Industries:

A JOURNAL OF ENGINEERING, ELECTRICITY, & CHEMISTRY

FOR THE

Mechanical and Manufacturing Trades.

VOL. IV.—JANUARY TO JUNE, 1888.

Offices:

LONDON: 22, WELLINGTON STREET, STRAND, W.C. MANCHESTER: 70, MARKET STREET.

GLASGOW: 62, ST. VINCENT STREET.

INDEX TO "INDUSTRIES."

Articles.

*(All Articles marked thus * are Illustrated.)*

Accumulators, Transformers or, 452
*Adams' "Vortex" Blast Pipe, 367
Admiralty Programme, The, 344
Agricultural and Dairy Schools, 329
*Air Propeller, An Improved, 370
Alcohol, Duty Free, 201
Alexandra Dock, Hull, The, Paper read before the Institution of Civil Engineers, by A. C. Hurtzig, M.Inst.C.E., 155
Alkali Waste, The Recovery of Sulphur from, Paper read before the Society of Chemical Industry, by A. M. Chance, 278
Alloys and Their Properties, 274, 300, 357
*Almond's Coupling, 110
*Alternate Current Transformers, Paper read before the Society of Telegraph Engineers and Electricians, by G. Kapp, 145
*Alternating Current Motor, Nicola Tesla's, Paper read before the American Institute of Electrical Engineers, by Nicola Tesla, 576
*Alternator, The Mordey, 542
*Ambler's Attachment for Monkey Wrenches, 328
Amendment of the Patent Law, 324
America, Boiler Explosion in, 352
America, The Recent Storm in, 328
American Electric Light Installations, Fire and Life Risks in, 524
American Field Gun, A New, 542
American Foundry Iron, Notes on, Paper read by W. J. Keep and Thomas Turner, Assoc. R.S.M., before the South Staffordshire Institute of Iron and Steel Works' Managers, 479
*American Hotel, Moving an, 491
*American Institute of Electrical Engineers, The, 576
American Warship Design, Paper read before the Institution of Naval Architects by W. John, 311
Analysis of the Gas Engine, The Thermo-Dynamic, Abstract of Paper read before the Manchester Association of Engineers, by H. Guthrie, 329
Antagonism, The Principle of, 500
Anti-Fouling Composition, 621
*Apparatus for Heating, Setting, and Removing Tyres, 162
*Apparatus, Improved Steam Sanding, 389
Architects, Engineers, and Surveyors, The Registration of, 298, 350
Architects, The Institution of Naval, 311, 337, 363, 389
Army and Navy Contracts, 393
Arsenal of Tientsin, The Eastern, 618, 638
Arsenic on Mild Steel, The Effects of, Paper read by F. W. Harbord and A. E. Tucker, before the Iron and Steel Institute, 513
Arsenic in Ore and Metal during Smelting and Purification Process, The Behaviour of, Paper read by Pattinson and Stead, before the Iron and Steel Institute, 512
Art Commission, A Japanese, 207
Artillery, Modern Heavy, 513
*Attachment for Monkey Wrenches, Ambler's, 328
*Automatic Bilge Cleaning Arrangement, 29
*Automatic Damper for Boiler Furnaces, 391
*Automatic Lubricator, Improved, 431
*Automatic Regulation of Dynamo Machines, 123
*Automatic Valves, Brough's, 355

*Backman's Helicoidal Lift, 120
*Balanced Hydraulic Lifts, 583
"Bar-Lock" Type Writer, The, 447
Basic Steel for Boilers, 299
Bell Telephone before the American Courts, The, 376
*Belt Gear for Testing Dynamos, 625
*Bending Machine, Improved, 157
Berdan's Combined Ram and Torpedo, 419
*Bernstein System of Electric Lighting, The, 69
Big Guns, Our, 142, 188
*Bilge Cleaning Arrangement, Automatic, 29
Bill, Mines (Limitation of Hours), 573
Bill, The Employers' Liability, 573
Bill, Weekly Wages, 621
Bimetallic Conference, The, 402
Birmingham and the Sea, Improved Communication between, 287
*Blast Pipe, Adams' "Vortex," 367
Bleaching, Electrolytic, Paper read before the Society of Chemical Industry, by C. F. Cross and E. J. Bevan, 456
Board of Trade and Shipowners, The, 546
*Boats, Proposed Designs for Surface Boats and Diving, Paper read before the Institution of Naval Architects, by Lieut. W. Hovgaard, 364
Boiler Explosion in America, 352
Boiler Explosion near Burns' Cottage, 248
*Boiler Explosion, Some Recent Official Reports on, 266, 340, 391, 502, 591
Boiler Explosion near Seaham Harbour, 614
*Boiler Explosions Act, 1882, Formal Investigation under the, 446
*Boiler Furnaces, Automatic Damper for, 391
*Boiler Shell Drill, Dalett's, 110
*Boiler, Turner's Improved Steam Engine and, 560
Boilers, Basic Steel for, 299
*Boilers, Combined Engines and, 337
Boilers, Inspection of, 526
*Boilers of the s.s. "City of Berlin," Engines and, 137
*Boilers of the Gunboat "Ceram," Engines and, 58
Boilers under Forced Draught on the Closed Stoke Hold System, Paper read before the Institution of Naval Architects, by T. Soper, R.N., 340
Boilers, Working and Test Pressure for Marine, Paper read before the Institute of Naval Architects, by R. Sennett, R.N., 337
Bottle Making by Machinery, Glass, 90
*Brace, An Improved Ratchet, 12
Brassey's Naval Annual, Lord, 324
*Breadner's Copper Damping Brush, 590
Bricks and Brick Making, Paper read before the Inventors' Institute, by William Johnson, 315
*Bridge, The Forth, 65, 288, 312, 345, 370, 599, 607
Bridge at Hooghly, The Erection of the "Jubilee," Paper read before the Institution of Civil Engineers, by Sir Bradford Leslie, K.C.I.E., M.Inst.C.E., 105
*Bright, The Late Sir Charles, 477, 502
British and Foreign Shipbuilding, 350
*British Empire Section of the Brussels Exhibition, 66
British Watch Industry, 633
*Brough's Automatic Valves, 355
*Brussels Exhibition, 1888, The, 66
Budget Debate, The, 376
Burns' Cottage, Boiler Explosion near, 248

Caird, Mr. James T., The late, 118
*Caissons, Travelling, 633
*Canada, Logging in, 4, 55, 80, 106
Canal Extension, 299, 428
Canal, The Panama, 90
*Cane Mill with Maceration Apparatus, Four-Roller, 188
Carbo-Dynamite, 645
Cardon Flax Scutching Machine, The, 374
Carriage of Fish, The Railway Companies and the, 247
*Casing for Locks, Improved, 570
Castings, Sound Copper, 608
*Castors, Rickinson's Improved, 614
Cement, The Effect of Sea Water on Portland, Paper read before the Society of Engineers, by Henry Faija, M.Inst.C.E., 322
Central Electric Light Station, The Leamington, 623
Central Station Lighting, Paper read before the Society of Telegraph Engineers and Electricians, by R. E. Crompton, 405, 432, 455
Central Station Lighting by Storage Batteries, 220
Central Station Lighting, On the Cost of, 276
*"Ceram," Engines and Boilers of the Gunboat, 58
Chemical Examination of Resins, The, 357
Chemical Industry, Society of, 44, 174, 226, 252, 277, 278, 407, 456, 457, 602, 648
Chemical Progress in 1887, 43
Chemical Reagents for Textile Fabrics, 252
Chemical Society of Paris, The, 625
Chemical Society, The, 174, 356
Chemistry of the Leaden Chamber, The, 251
China and Europe, Telegraphic Communication between, 470
China or Tender Porcelain, English, Abstract of Paper read before the Society of Chemical Industry, by Thomas Bayley, 252
Chlorine, The Manufacture of, Paper read before the Society of Chemical Industry, by C. T. Kingzett, 457
*Chronograph Dial, Trotter's, 15
*Chuck, Improved Jaw, 455
*Chuck, Reversible Jaw, 15
*"City of Berlin," Engines of the s.s., 137
*"City of New York," The s.s., 270
Civil Engineers, The Institution of, 52, 105, 155, 188, 250, 286, 390, 440, 536, 585
Civil and Mechanical Engineers' Society, 355
*"Close Grip" Sash Fastener, The, 513
Clyde, Serious Collision during a Trial Trip on the, 618
Clyde Shipbuilding, 170, 319, 429, 519, 598
Coal, Combustion of, Abstract of Paper read before the Chemical Society of Paris, by Scheurer-Kestner, 625
Coal Distillation, Studies in, Paper read before the Society of Chemical Industry, by Lewis T. Wright, 174
Coal Gas, A New Method of Removing Sulphur Compounds from, Paper read before the Society of Chemical Industry, by A. Gordon Salomon, 44
Coal Getter, Moulds' Patent, 185
*Coal Getting Machine, Hydraulic, 574, 609
Coal, Iron, and Cognate Industries, 36, 168, 270, 430, 498, 594
Coal in 1887, The Production of, 299
Coal Tar Derivative, Saccharine, a New, 553
Collieries, Safety Lamps in, Abstract of a Paper read by W. H. Preece, F.R.S., before the Royal Institution of Great Britain, 171
Colliery Warnings, 12
Collisions at Sea, The Influence of Size and Speed on, Paper read before the Institution of Naval Architects, by J. H. Heck, 390
Collision During a Trial Trip on the Clyde, Serious, 618
Colour, A New Instrument for the Measurement of, Paper read by H. le Neve Foster, before the Iron and Steel Institute, 513
Colour, The Origin of, Paper read before the Chemical Society, by Professor Henry E. Armstrong, F.R.S., 356
*Combined Gas Engine and Pump, 422
*Combined Engines and Boilers, 337
*Combined Pick and Spade, 276
Combined Ram and Torpedo, Berdan's, 419
Combustion of Coal, Abstract of Paper read before the Chemical Society of Paris, by Scheurer-Kestner, 625
Commerce during 1887, Industries and, 1, 25
Commercial Education in Japan, 327
Commission, A Japanese Art, 207
Communication between Birmingham and the Sea, Improved, 287
Composition, Anti-Fouling, 621
*Compound Steam Turbines, Paper read before North-East Coast Institution of Engineers and Shipbuilders, by the Hon. C. A. Parson, 41
*Compressed Air, Photography in, 400
Compressed Oil Gas and its Applications, Paper read before the Institution of Civil Engineers, by Arthur Ayres, M.Inst.C.E., 390
Condition of Self Excitation of a Dynamo Machine, The, Paper read before the Physical Society, by Professor S. P. Thompson, 503
Congress, Life Saving and Preservation, 638
Conference, The Bimetallic, 402
Contracts, Army and Navy, 393
*Contraction of Metals in Magnetic Fields, The Elongation and, 377
Controversialist, Professor Huxley as a, 194
Conversazione at the Royal Society, 502
Copper "Boom" and Copper Mining, The, 70
Copper Castings, Sound, 608
*Copper Damping Brush, Breadner's, 590
Cost of Central Station Lighting, On the, 276
Cotton Dyeing, The Revolution in, 600
Cotton Industry and Technical Education, The, 208
Cotton Spinning Limited Companies, 64
Cotton Trade, The, 350
*Coupling, Almond's, 110
*Cox-Walker's Telemeter, 199
Crampton, The late Mr. Thomas R., 426, 453
*"Crandall" Type Writer, The, 479
*Crucible Furnace, Otto's, 149
*Cruiser "Reina Regente," The Spanish, 88
*Cutting Off Saw, Swing, 315
Cycle Show, The Stanley, 114
*"Cyclone" Dust Collector, The, 450
*Cyclone Oil Burner, The, 491
*"Cyclone" Pulveriser, The, 566
*Cylinder Lubricator, Improved, 487

Dairy Schools, Agricultural and, 329
*Dalett's Boiler Shell Drill, 110
*Damper for Boiler Furnaces, Automatic, 391
*Damping Brush, Breadner's Copper, 590
Debate, The Budget, 376
Defences of the United Kingdom, The Naval, 548
Designs in India, The Protection of Inventions and, 287
Development of Modern Weapons Considered in Relation to the Designs of War Ships, The, Paper read before the Institution of Naval Architects, by Captain Hubert Grenfell, R.N., 311
Development of Shipping and Shipbuilding, The Commercial, 14, 38
*Diagrams Relating to the Properties of Water and Saturated Steam, 426, 450
*Dial, Trotter's Chronograph, 15
*Discs for Heating and Cooling Purposes, Improved, 237
Distribution of Electricity, Paper read by J. K. D. Mackenzie, before the Society of Telegraph Engineers and Electricians, 173
Distribution of Hydraulic Power in London, The, Paper read before the Institution of Civil Engineers, by E. Bayzand Ellington, M.Inst.C.E., 440
*Diving Boats, Proposed Designs for Surface Boats and, Paper read before the Institution of Naval Architects, by Lieut. W. Hovgaard, 364

Digitized by Google

Dock, Hull, The Alexandra, Paper read before the Institution of Civil Engineers, by A. C. Hurtzig, M.Inst.C.E., 155
*Docks, Pontoon and Floating, Paper read by A. Taylor, before the North-East Coast Institution of Engineers and Shipbuilders, 514
Dockyard v. Private Contract Work, 596, 607
*Draught, Forced, Paper read before the Institution of Naval Architects, by J. R. Fothergill, 339
*Drill, Dalett's Boiler Shell, 110
*Drilling Machine, Hodson's Portable, 586
*Drilling Machine, Improved Triple Radial, 114
*Ducretet's Oil Filter for Gas Engines, 535
*Duplex Pumping Engine, 12
*Dust Collector, The "Cyclone," 450
Duty Free Alcohol, 201
Dyeing, The Revolution in Cotton, 600
Dynamite Gun, The, 237
*Dynamo, Fifty Kilo-Watt Goolden-Ravenshaw, 522
*Dynamo, The "Leeds," 518
Dynamo Machine, The Condition of Self Excitation of a, Paper read before the Physical Society, by Professor S. P. Thompson, 503
*Dynamo Machines, Automatic Regulation of, 123
Dynamo Machines, The Magnetic Circuit in, Paper read before the Physical Society, by Professor Perry, 304
*Dynamometer, A New Transmission, 122
*Dynamos, Belt Gear for Testing, 625

Economy Trials of a Non-Condensing Steam Engine, Paper read before the Institution of Civil Engineers, by P. W. Willans, M.Inst.C.E., 286
Edison Glow Lamp Patents, The, 428, 452, 476, 525, 620
Education, The Cotton Industry and Technical, 208
Education, Mr. Goschen on, 168
Education in Japan, Commercial, 327
Education in New South Wales, Technical, 524
Effect of Oil on Waves, The, 446
Effect of Sea Water on Portland Cement, The, Paper read before the Society of Engineers, by Henry Faija, M.Inst.C.E., 322
Efficiency of Incandescent Lamps with Direct and Alternate Currents, Paper read before the Physical Society, by Professor Ayrton, 214
Efficiency of Steam Ships from the Owners' Point of View, The, 259
*Electric Balance, Sir William Thomson's Composite, 538
Electric Currents, The Heating Effects of, 432
*Electric Light Installation at the Botanical Gardens, Manchester, 599
Electric Light Installations, Fire and Life Risks in American, 524
*Electric Light Installations at Hamburg, Hydraulic Power and, 302
Electric Light in the City of London, The, 195
Electric Light Legislation, 246
*Electric Light Plant, Portable, 67
*Electric Lighting at the Glasgow International Exhibition, 1888, 396
Electric Lighting, Fire Risks in, Paper read before the Society of Telegraph Engineers and Electricians, by W. H. Preece, F.R.S., 504
*Electric Lighting, The Bernstein System of, 69
*Electric Lighting at the *Scotsman* Offices, 504
Electric Lighting at the Victoria Hotel, Manchester, 430
Electric Lighting in Switzerland, 121
Electric Lighting in the United States, The Growth of, 197
Electric Light Station at Leamington, Central, 623
Electric Light Wires, Underground, 272, 330
*Electric Railways, Main Switch for, 199
Electric Street Lighting, 220
Electric Tramway, The Lineff, 116
*Electrical Measuring Instruments, Sir William Thomson's New Standard, 93
Electrical Progress in 1887, 40
Electrical Stress, Paper read before the Society of Telegraph Engineers and Electricians, by Professor A. W. Rücker and C. V. Boys, 330
*Electrical Submarine Vessel, The "Waddington," 155
Electrical Transmission of Energy, 18
*Electricians, The Society of Telegraph Engineers and, 116, 145, 173, 198, 224, 277, 330, 405, 432, 453, 455, 504, 518, 550, 574
*Electricity as Applied to Engineering, Prospects of, Paper read before the Institution of Mechanical Engineers, by Wm. Geipel, 146, 172
Electricity, Distribution of, Paper read by J. K. D. Mackenzie, before the Society of Telegraph Engineers and Electricians, 173
Electricity, Pumping in Mines by, 326
*Electro-Dynamic Rotation by Means of Alternating Currents, 505
Electrolytic Bleaching, Paper read before the Society of Chemical Industry, by C. F. Cross and E. J. Bevan, 456
Electromotors, The Governing of, Paper read before the Physical Society, by Professor Ayrton and Professor Perry, 549
Elementary Schools, Instruction in, 422
*Elements and Meta-Elements, 382
*Elevator, Improved Floating Grain, 609
*Elongation and Contraction of Metals in Magnetic Fields, The, 377
*Emery Testing Machine, Paper read before the Institution of Mechanical Engineers, by H. R. Towne, 590, 631
Employers' Liability Bill, The, 573
Employers' Liability Legislation, 403
*Energy, Electrical Transmission of, 18
Engine, Report on the "Griffin" Patent Gas, 379
*Engine, The Priestman Petroleum, 490
Engine, The Thermo-Dynamic Analysis of the Gas, Abstract of Paper read before the Manchester Association of Engineers, by H. Guthrie, 329
*Engine, The Westinghouse, 631
*Engineering, Progress in 1887, 32
Engineers and Surveyors, The Registration of Architects, 298, 350
*Engineers, Manchester Association of, 52, 136, 292, 329
Engineers, The Institution of Civil, 52, 105, 155, 188, 250, 286, 390, 440, 536, 585
*Engineers, The Institution of Mechanical, 3, 27, 130, 146, 172, 463, 465, 590, 631
Engineers and Shipbuilders in Scotland, The Institution of, 41, 514, 642
Engineers' Society, Civil and Mechanical, 355
Engineers, The Society of, 322, 407
*Engines and Boilers, Combined, 337
*Engines and Boilers of the Gunboat "Ceram," 58
*Engines and Boilers of the s.s. "City of Berlin," 137
*Engines, Petroleum Vapour, 597
Engines, The Horse Power of Marine, 642
*Engines of the s.s. "Queen Victoria," The Paddle, 88, 474, 498
*Engines, The Theory of Hot Air and Gas, 233
*Engines, Triple Expansion Launch, 207
England, Farm Homesteads of, 250, 467
England, Possible Naval Combination against, 261
England, Tobacco Culture in, 287
English China or Tender Porcelain, Abstract of Paper read before the Society of Chemical Industry, by Thomas Bayley, 252
English Fisheries, 396
English Railway, The Working of an, 226
*Engraving Machine, Taylor's, 370
Erection of the "Jubilee" Bridge at Hooghly, The, Paper read before the Institution of Civil Engineers, by Sir Bradford Leslie, K.C.I.E., M.Inst.C.E., 105
*Erection of the Superstructure of the Forth Bridge, Paper read before the Institution of Engineers and Shipbuilders in Scotland, by Andrew S. Biggart, C.E., 312
Europe, Telegraphic Communication between China and, 470
Examination of Resins, The Chemical, 357
*Excavator, Garvie's Improved, 285
Exhibition at the Crystal Palace, Photographic, 197
*Exhibition (1888), Glasgow International, 396 415, 474, 501, 583, 647
Exhibition in Munich, 157
*Exhibition (1888), The Brussels, 66
Exhibition, The Irish, 570
Exhibition, The Italian, 494
*Exhibition, The Manchester Royal Jubilee, 181, 285, 366, 392, 418, 439
*Expanding Pulleys, Improved, 344
Experiments on Models used at the Admiralty Experiment Works, The Constant System of Notation of Results of, Paper read before the Institution of Naval Architects, by R. E. Froude, 363
Explosion near Burns' Cottage, Boiler, 248
Explosion near Seaham Harbour, Boiler, 614
Explosive "Hellhoffite," The New, 274
Extension, Canal, 299, 428

Fabrics, Chemical Reagents of Textile, 252
*Facing Lathe, An Improved, 51
Farm Homesteads of England, 250, 467
*Feed Water Heater and Purifier, 319
*Feed Water Heater, Improved, 615
Field Gun, A New American, 542
*Field Guns, Steel for, Paper read before the Iron and Steel Institute, by Major L. Cubillo, 511, 526
Fire and Life Risks in American Electric Light Installations, 524
Fire Risks in Electric Lighting, Paper read before the Society of Telegraph Engineers and Electricians, by W. H. Preece, F.R.S., 504
*Fire Telegraphs, The New York, 405
Fire Telegraphy, Statistics of, Paper read before the Society of Telegraph Engineers and Electricians, by R. von Fischer Treuenfeld, F.R.G.S., 277
Fisheries, English, 396
*Fishery, The Scottish Herring, 156, 183
Flax Scutching Machine, The Cardon, 374
*Floating Docks, Pontoon and, Paper read by A. Taylor, before the North-East Coast Institution of Engineers and Shipbuilders, 514
*Floating Grain Elevator, Improved, 609
*Fluorine, Isolation of, 44
*Forced Draught, Paper read before the Institute of Naval Architects, by J. R. Fothergill, 339
Foreign Shipbuilding, British and, 350
Foreign Trade, Our, 192
*Forth Bridge, The, 65, 288, 312, 345, 370, 599, 607
*Forth Bridge, Lighting Arrangements at the, 599.
Fortification of Our Ports, The, 272
Foundry Iron, Keep's Tests for, Paper read before the South Staffordshire Institute of Iron and Steel Works' Managers, by Thomas Turner, Assoc.R.S.M., 527
Foundry Iron, Notes on American, Paper read by W. J. Keep and Thomas Turner, Assoc. R.S.M., before the South Staffordshire Institute of Iron and Steel Works' Managers, 479
*Foundry Work, Notes on, 84, 131, 235, 416, 537
*Friction, Third Report of the Research Committee on, Read at the Institution of Mechanical Engineers, 465
*Friern Barnet Sewage Works, 200
*Furnace, Otto's Crucible, 149.
Fuses, Safety, Paper read before the Society of Telegraph Engineers and Electricians, by C. Cockburn, 116

Galvanometer and Lamp, Portable Reflecting, Paper read before the Physical Society, by G. L. Addenbrooke, 304
*Garvie's Improved Excavator, 285
*Gas Engine and Pump, Combined, 422
*Gas Engine, Report on the "Griffin" Patent, 379
Gas Engine, The Thermo-Dynamic Analysis of the, Abstract of Paper read before the Manchester Association of Engineers, by H. Guthrie, 329
*Gas Engines, Ducretet's Oil Filter for, 535
Gas Engines, The Theory of Hot Air and, 233
*Glasgow International Exhibition, 1888, 396, 415, 474, 501, 583, 647
Glass Bottle Making by Machinery, 90
Glazes for Porcelain Ware, 480
Glow Lamp Patents, The Edison, 428, 452, 476, 525, 620
Glow Lamp, The Seel, 146
Gold Fields, The Welsh, 70
*Goolden-Ravenshaw Dynamo, Fifty Kilo-Watt, 522
Goschen on Education, Mr., 168
Governing of Electromotors, The, Paper read before the Physical Society, by Professor Ayrton and Professor Perry, 549
Government Bill, The Local, 325
Government Tests of the Strength of Spirits, Paper read before the Society of Chemical Industry, by Dr. B. Derham, 407
*Grain Elevator, Improved Floating, 609
Gray, Professor Asa, The Late, 118
*"Griffin" Patent Gas Engine, Report on the, 379
*Grinding Machine, Universal Face and Angle, 352
Gun, A New American Field, 542
Gun, The Dynamite, 237
Guns in the United States, Heavy, 642
Guns, Our Big, 142, 188
Guns, Steel Castings for the Manufacture of, Paper read by Major L. Cubillo, before the Iron and Steel Institute, 512

*Hamburg, Hydraulic Power and Electric Light Installations at, 302
*Hargreaves' Thermo-Motor, 8
Harrison, The Late Mr. T. E., 326
*Health in Engineering Workshops, Abstract of a Paper read before the Manchester Association of Engineers, by J. Corbett, 136
Heating Effects of Electric Currents, The, 432
"Hellhoffite," The New Explosive, 274
*Henderson's Mechanical Stoker, 392
*Herring Fishery, The Scottish, 156, 183
*Hetherington-Draper Sprinkler, The, 249
*"Hetherington" Saw, The, 77
*High Pressure Turbines, 129
*Hodson's Portable Drilling Machine, 586
*Hoist, Improved, 514
*Hole Cutting Machine, Smiles', 36
*Holroyd Smith Magnetic Separator, The, 381
Horse Power of Marine Engines, The, 642
Hot Air and Gas Engines, The Theory of, 233
*Hughes' Lecture Lantern, 642
Huxley as a Controversialist, Professor, 194
*Hydraulic Coal Getting Machine, 574, 609
*Hydraulic Lifts, Balanced, 583
*Hydraulic Power and Electric Light Installations at Hamburg, 302
Hydraulic Power in London, The Distribution of, Paper read before the Institution of Civil Engineers, by E. Bayzand Ellington, M.Inst.C.E., 440

*Imperfection in Mild Steel Plates Considered Chemically, An, Paper read before the Iron and Steel Institute, by H. Eccles, 489, 494
Importations, Temporary, 117
Imports into Sicily, 2
*Improved Automatic Lubricator, 431
*Improved Bending Machine, 157
*Improved Casing for Locks, 570
*Improved Castors, Rickinson's, 614
*Improved Cylinder Lubricator, 487
*Improved Discs for Heating and Cooling Purposes, 237
*Improved Expanding Pulleys, 344
*Improved Feed Water Heater, 615
*Improved Floating Grain Elevator, 609
*Improved Hoist, 514
*Improved Jaw Chuck, 455
*Improved Loom, An, 463

Breech-Loading Fire Arm, 179*
Breech Mechanism for Ordnance, 411
Brick Machine, 48*, 76*, 256*, 460
Brush Holders for Dynamos, 461*
Brushes of Dynamos and Motors, 335
Brushing Yarns and Fabrics, Machine for, 229
Buckets, Swing, 309
Burner, Hydrocarbon Oil, 258*
Burst Tubes, Stopper for, 75*
Button Making Machines, 284
Buttons, Making Collar, 180*

Cable, Traction, 206
Cable Tramway, 582*, 652*
Cage for Carrying Fibre, 462
Calcining Furnaces, 100
Calcium Hydroxide, 413
Calendering Machines, 484*
Cane, Diffuser for Sugar, 101
Cane, Extraction of Saccharine Matter from, 21*
Cap Spinning and Twisting Frames, 581
Car Coupling, 232*
Carbonate of Iron, 510
Carbonate of Soda, 653*
Carbonic Acid, 75*
Carbonic Acid, Liquid, 284*
Carbonising Vegetable Matters in Wool, 414
Cardboard Cutter, 153
Carding Cloth, 510
Carding Engines, 21, 22*, 74, 152, 282, 334, 361, 462, 558, 605
Carding Engine Cylinders, Driving, 436
Carding Engines, Adjusting, 102
Carding Engines, Cleaning, 534
Cards, Jacquard, 582
Carriages, Heating Railway, 154
Carrying Fibres, Cage for, 462
Cartridge for Oiling Sea, 486
Cast Steel, 152
Casting Metals, 153, 533*
Casting Metals under Pressure, 385*
Casting Ordnance, 558*
Caustic Ash, 387*
Cement, 283
Cement and Lime Kilns, 630
Centrifugal Filters, 414*
Chaff Cutter, 509
Chain Wheels and Pitch Chains, 49, 205
Chains, Elevating Band, 388
Chlorates of Alkalies, 387
Chlorine, 606
Chromium Sulphocyanide, 179
Churns, 180
Circular Saws, 438*
Cleaner for Flues, 486*, 654*
Cleaning Toothed Feed Rolls, 310
Cleaning Tubes, 654*
Closing the Lids of Tins, 258*
Cloth Finishing Machine, Feed for, 414
Clutch, 533
Clutches, Friction, 75, 101*, 629
Coal Cutting Machine, 49, 258*
Coal Mining, 509
Coal, Shipping, 508
Coating for Iron, 206
Coating Metals with Tin, 232, 309, 361, 486*
Cobalt, Electro-Deposition of, 283
Cobalt, Sulphate of, 557
Cold Drawing Machines, 100
Collar Buttons, Machine for Making, 180*
Collectors, Dust, 534, 582
Colour Printing Machines, 436*
Colouring Matters, 23, 49, 75, 437, 461
Combing Machines, 255, 628
Compound Steam Engines, 100, 177,* 359
Compressed Air and Gas Engine, 509*
Compressors, 128*
Condensers, 76*
Conductors, Insulation of Electrical, 180, 437*
Conduits, Underground, 23
Consumption of Smoke, 206
Controlling and Measuring the Supply of Water, 534
Controlling Apparatus, Electrical (see Electrical Controlling Apparatus)
Controlling the Supply of Water or Gas Automatically, 510
Converters, 102, 556*, 652
Conveying Minerals, Endless Bands for, 486
Cop-Tube Machine, 50
Copper, Electrolysing, 310
Copper from Ores, Extracting, 258, 437
Copper Pyrites, Treatment of, 257
Corn Planting Attachment for Ploughs, 388
Cotton Batting, 582
Cotton, Drying, 385
Cotton Gins, 462, 510, 630, 654
Cotton, Opening and Cleaning, 153
Cotton Seed Oil, Refining, 284
Cotton Waste Machines, 460
Coupling, Car, 76*, 232*, 558*
Coupling Pipes, 534*
Covering Electric Conductors with Lead, 100*
Covers for Shafts, 258
Cranes, Retiring Bearings for Travelling, 308
Cranes, Ship, 74*
Cranes for Ships, Hydraulic, 230*
Cross Weaving, Loom for, 438
Crushing and Grinding Mills, 333
Currents, Electric (see Electric Currents)
Cushioning Device for Pistons, 258
Cut-off Arrangements, 232*
Cut-out, Electrical (see Electrical Cut-out)
Cutter for Cardboard, 153
Cyanogen Compounds, 101
Cylinders, Safety Apparatus for Steam, 388*

Dandy Rolls for Paper Making Machines, 460
Decorating Glass, 49*
Decorating Tin Plates, 388, 462
Dextrine, 309
Die for Screw Making Machines, 362
Dies for Making Twist Drills, 630*
Dies, Machine for Making, 629
Diffuser for Sugar Cane, 101
Disc Pumps and Blowers, 360*
Disintegrators, 556
Distillers for Sea Water, 22*, 23, 361*
Distilling Shale, 510*
Doors, Double, 180
Doors for Furnaces, 74
Doubling and Twisting Machines, 484*, 605*, 652
Doubling and Winding Machines, 256
Dowel Pins, Making, 153
Drawing Machine, Cold, 100
Dresser for Band Saws, Side, 486*
Dressing Hides, 557*
Drill, Rock, 74, 180*, 362
Drills, Dies for Making Twist, 630*
Drills, Twist, 484
Drying Cotton, 385
Drying Fabrics, Machine for, 460
Drying, Sizing, and Warping Machines, 282*
Dust Collectors, 534, 582
Dyeing Apparatus, 606*
Dyeing and Scouring Machine, 232
Dyeing Fabrics, 309, 310
Dyeing with Aniline Black, 48, 153, 205
Dyes and Printing Ink, 461
Dynamite, 127
Dynamo and Engine, Combined, 257, 283*, 335
Dynamo Brushes, 335, 461*
Dynamos, 23, 127, 205, 231, 256, 283, 309, 309*, 334, 387, 387*, 413, 460, 461*, 485, 509, 510, 534*, 629, 653
Dynamos, Regulating, 153*, 557, 581

Economiser, Fuel, 508*
Edge Planing Machines, 533
Elastic Fabrics, 179
Electric Arc Lamps, 436, 485
Electric Circuits, Safety Device for, 205
Electric Conductor, 310

FRIDAY, 6TH JANUARY, 1888. VOL. IV.

Industries.

INDUSTRIES AND COMMERCE DURING 1887.

FOLLOWING out the arrangement we adopted at the beginning of last year we intend in this and following issues to place before our readers a review of the trade and industrial progress of the past year. We shall first review in a general way our industrial and commercial position as regards 1887, and afterwards consider separately the technical progress made during the past year in the three main subjects taken up by *Industries*, viz., Engineering, Electricity, and Chemistry. The circumstances of trade and commerce during 1887 have been decidedly mixed and variable. In the early part of the year hopes ran high, and there was every prospect of a substantial revival of business. Values appreciated generally, the volume of trade increased, there was a more active demand all round, and the outlook as a whole was such as to inspire confidence and buoyancy of feeling. But this condition of things did not long continue. The remarkable prosperity of the United States was not reflected to the same extent as it has been in previous years in the recuperation of British industry. The Colonial demands were not appreciably greater than usual. The new countries in Africa and our own territorial acquisitions in Burmah did not quite answer expectations, and have indeed scarcely had time as yet to develop. China, which for a time showed a strong disposition to come into the field with large demands for railway materials, has actually limited those demands to a beggarly 30,000 or 40,000 tons. The political horizon became unsettled in Europe, if, indeed, it had ever been anything else; and rumours of wars did not tend to increase the hopes that the future had really better times in store. The adoption by the Canadian Parliament of a new scale of Customs duties that were less favourable than before to certain leading descriptions of iron and steel, excited fears that our Colonial markets were by no means so secure and so capable of indefinite expansion as had been imagined. Agriculture continued depressed, and in regard to several leading products prices actually suffered a further fall. The labour market became more and more glutted, as a consequence of the migration of agricultural labourers into the cities and towns; and this fact, while it had the effect of keeping down the wages of those who were employed in industrial occupations, created a considerable amount of distress. All this tended to depress the markets, and to prevent prices from improving during the greater part of the year. But in the last quarter of 1887 there were again unmistakable signs and tokens of a revival, although the immediate occasion was far from manifest. Copper was one of the first materials to exhibit the change, and for a time prices in the copper market underwent violent fluctuations, until the price settled down at about double that of the same time in 1886. Iron and steel followed suit, but not to anything like the same extent. Textiles have been comparatively unaffected, and agricultural produce has not reflected the improvement as might have been anticipated. But in regard to a number of minor industries, there has been a real appreciation of prices and of demand. The political outlook is, however, still far from satisfactory. All the capitals of Europe are more or less in a condition of ferment, if not of panic. The rumours as to the intentions and policies of the several great Powers are as contradictory and unreliable as such rumours usually are; and all that can safely be predicted is that until political apprehensions are more or less abated, business is not likely to flow in its natural channels.

AGRICULTURE.

We must seek for a true index to the condition of agriculture in two paramount sources of information—the agricultural returns issued by the Privy Council, and the import and export returns issued by the Board of Trade. The former show that there has actually been an increase of 24,000 acres in the area of land under cultivation in Great Britain in 1887 as compared with 1886, and that there has been a decrease of 114,200 acres in the area of corn crops under cultivation. In Ireland, however, there has been a decrease of 82,000 acres in the area under cultivation. The decrease of cultivated area in the United Kingdom has not been so considerable as was generally expected. The common impression has been that in most of the purely agricultural counties many farms were unlet, and that the land had been allowed to go out of cultivation because it did not repay the cost of farming it. The official returns, happily, do not lend much countenance to this view. They show, however, an increasing tendency to substitute grass and clover for cereal crops, which means, of course, that less labour is employed upon the land, and that we must become increasingly dependent upon other countries for our breadstuffs. There has also, during 1887, been an increase in the area of land under flax, which is a hopeful sign. We are now importing more than a million and a half hundred-weights of flax from foreign countries, chiefly from Russia. During 1887 this supply was imported at a lower price than in either of the several preceding years, the average having been £1. 14s. 6d. per cwt. in 1887, and £1. 17s. 6d. in 1886. It is to be presumed, therefore, that the flax growers in Great Britain and Ireland did not obtain very satisfactory prices during 1887. But it has been proved that a large area of the land of this country is suitable for flax cultivation, and there appears to be a disposition in certain quarters to make a fuller trial in this direction.

Regarding the extent and character of foreign competition in agricultural produce during 1887, we find that the imports of the leading descriptions of agricultural produce during that year have been as follows:—

	Imports during the first eleven months of 1887.		1886.		Increase in 1887.		Decrease in 1887.
	1=1000cwt.				1=1000cwt.		
Wheat	50,775	...	44,052	.....	6723	...	—
Wheat meal and flour	16,442	...	13,465	.....	2977	...	—
Barley	11,603	...	11,869	.....	—	...	266
Oats	12,825	...	12,467	.....	358	...	—
Indian corn	29,054	...	29,364	.....	—	...	310
Fresh beef	604	...	755	.....	—	...	151
Fresh mutton	703	...	584	.....	119	...	—
Butter	1406	...	1436	.....	—	...	30
Cheese	1721	...	1630	.....	91	...	—
Potatoes	2648	...	2595	.....	53	...	—

When we take into account the fact that the population of this country is increasing at the rate of about 400,000 per annum, the above figures do not indicate an excess of imports that would seem to be out of proportion to the natural growth of the population, taking one product with another. Prices have again ruled very low. This is sufficiently evidenced by the fact that the total imports of food during the first eleven months of 1887 were officially valued at 105 millions sterling, as compared with 100½ millions in 1886, and 114 millions in 1885. The average recorded value of the imported wheat during 1887 has been rather over that of 1886, but under that of any previous year, the figures being—

	s.	
1887	7·7	per cwt.
1886	7·5	„
1885	7·8	„
1884	8·4	„
1883	9·8	„

For a part of 1887, the price of wheat was under 29s. per quarter, but towards the close of the year it slightly improved. With hardly any better prices for their own produce than in the previous year, it almost goes without saying that agriculturists have not been able to render that help to industries and to trade generally that would have come with better times.

THE COAL INDUSTRY.

There has seldom, if ever, within recent years, at all events, been a period of such entire and unmitigated depression as the coal trade has witnessed during 1887. This has more especially been the case with steam coal. The range of prices in every branch of the trade has been exceptionally low, and it appears probable that they will continue so. The redeeming feature in the trade is the increase in the quantities of coal exported and shipped for the use of steamers engaged in the foreign trade. These have compared for the first eleven months of each of the last two years as under:—

	1887. Tons.		1886. Tons.		Increase in 1887. Tons.
Exported	22,362,768	...	21,540,241	...	822,527
Foreign trade steamers	6,285,039	...	6,142,367	...	142,669
Totals	28,647,807	...	27,682,608	...	965,196
Add probable exports, &c., in December	2,446,291	...	2,300,690*	...	145,601
Totals	31,094,098	...	29,983,298	...	1,110,800

* Actual quantity.

According to this estimation, the consumption of coal from these two sources is likely to exceed by about a million tons the consumption for 1886. But this increase has been accompanied by a decrease in price, so that coal owners have not gained much advantage by the larger demand; and where pits have been working, as many of them are now doing, at an absolute loss, the improvement does not afford much cause for satisfaction. The average price of the coal shipped for export in 1887 has only been 8·3s. per ton, as compared with 8·4s. per ton in 1886, and 8·9s. per ton in 1885. The decrease of price on 1886 has certainly not been large; but the trade is now worked on such an extremely narrow margin, that even a very small difference in price has an appreciable influence on the business of many large firms.

It is too early as yet to make any estimate of a reliable character as to the total coal output of 1887. The increased activity in iron, steel, and other works in which coal is largely consumed, coupled with the increase in the quantities exported and used for shipping purposes, and the continually increasing domestic consumption, would justify the expectation that the output was greater than in 1886. The general feeling appears to be that coal has been too actively produced, and that as long as production is so far ahead of consumption as it now is, there is little likelihood of any material rise in prices. For this reason the miners of some leading districts have been taking steps to bring about a reduction of output. There has not, however, been sufficient cohesion and unanimity among themselves to carry this object generally into effect. The movement in question might create a revival in the coal trade, so long as it was general; but if it was only partially adopted, it is manifest that its only influence, so long as it lasted—which could not, in that case, be very long—would be to benefit particular districts at the cost of others. Nor should it be forgotten that, while the very low prices recently current have been extremely unsatisfactory to the coal trade, as a trade, they have been of great advantage to other industries, and to the general community. A large increase of price is certainly not desirable. The coal miners already show a disposition to "take time by the forelock," and with the first faint streaks of dawn in the commercial horizon, they have been putting forward demands and claims which would be likely to deprive the owners largely, if not wholly, of any possible improvement. In one district, indeed—that of Monmouth—the men have been agitating for "eight hours per day, five days per week, a week's holiday early in the New Year, and a 10 per cent. advance." This is a fairly "large order" for a district in which the owners have for a year or two found it most difficult to earn a 2½ per cent. dividend.

Digitized by Google

The fact has probably not yet been sufficiently appreciated that the range of prices during 1886 was lower than it has ever been in the history of the coal trade, so far as reliable statistics are at command. The official value of the 157½ millions of tons of coal raised in that year is £38,145,000, being an average of only 4·8s. per ton, as compared with 5·1s. in 1885, and 5·4s. in 1884. There has thus been an estimated fall of ·6s., or rather over 6d. per ton, in the interval, whilst during 1887, the condition of the market has certainly not improved. It needs not much argument or evidence to show that this is an average price at which the profits must almost entirely disappear, especially as it is coincident with legislation that is calculated to increase, in however small a degree, the cost of production. The process of "natural selection" has now been going on in the coal trade for some years. During the past year some of the weaker firms and the worst collieries have gone to the wall. The number of collieries in operation has been further reduced, and the efforts of coal owners have been directed to obtaining the largest possible output against the more or less invariable standing charges. The miners have also, in general, been working very steadily, so that there has been very little interruption to work.

THE IRON AND STEEL INDUSTRIES.

The year 1887 has been a much better year for the iron trade, as a whole, than either of the two previous years. Prices have not picked up, as it was confidently expected they would do from the appearances of the early part of the year; but the volume of production has considerably exceeded that of 1886. The exports of most varieties of iron and steel show that there has been a substantial improvement in the foreign trade. This is especially noticeable in railroad iron and tin plates. Stocks have decreased appreciably in the Cleveland district and in one or two others. The range of prices remained low until the closing months of the year, when pig iron, plates and angles, and some minor descriptions improved. Scotch warrants rose during the last days of November and early in December by 2s. to 3s. per ton, and Cleveland iron followed, in sympathy with this movement. But there is a widespread impression that this is not altogether due to increased demand, since it followed upon the close of the navigation season instead of preceding that event. Whether speculative operations have really been at the bottom of the spurt time will show. The fact, however, remains that rails and plates have been in much better demand. The demand from the United States has been larger than in either of the two preceding years, and so with our Indian and Colonial requirements, one order of 40,000 tons of rails for Australia and another of 30,000 tons for South America having been placed a few weeks ago. Shipbuilding iron and steel are also much more inquired after. There is, indeed, a tolerably widespread idea that we are on the eve of a substantial revival of the shipbuilding trade, in which, of course, makers of plates and angles will at once participate. Steel is now all but universally used in shipbuilding, and hence the principal firms that formerly produced iron plates and angles have now, for the most part, laid down steel plant. There is, however, reason to believe that the steel making plant already laid down to supply shipbuilding requirements is quite equal to the productive resources formerly available in iron. The basic Bessemer process has made less progress during the past year than the basic open hearth process. There are several firms going into the latter trade, which is likely by this time next year to be of considerable extent. Finished iron, nevertheless, continues to live; the trade dies hard in Staffordshire, although it may be regarded as all but extinct in the North of England and Wales, which formerly produced well on to a million tons a year.

The increase in the value of our exports of iron and steel for the eleven months ended 30th November has been 2¾ millions sterling over the year 1886. But this increase is much more considerable than it really appears from this figure, for the downward tendency in the prices of some leading commodities has been considerable, although in other cases there has been a real improvement of prices. It may therefore be taken that there has been a much greater increase of volume than of values. This is specially noticeable in some leading articles, such, for example, as tin plates, of which the value of the 247,042 tons exported to America in 1887 is returned at £3,274,485, as compared with £3,383,200, the declared value of the 242,130 tons exported to the same country in 1886. In this case the average value in 1886 was £14 per ton, whereas in 1887 it was only £13·2 per ton. Pig iron, on the contrary, shows a slight increase of value, the figures having been for the eleven months ending 30th November:—

Year.	Quantity. Tons.	Value. £	Average per ton to nearest decimal. £
1887	1,062,637	2,528,626	2·4
1886	988,354	2,128,470	2·2
Increase in 1887	74,283	400,156	

Coming now to railroad iron of various descriptions, we find that there has been a decrease of value in 1887 as compared with 1886, the figures for the eleven months comparing as under:—

Year.	Quantity. Tons.	Value. £	Average per ton to nearest decimal. £
1887	914,840	4,161,486	4·5
1886	688,635	3,463,533	5·0
Increase in 1887	226,205	697,953	

Of other descriptions of iron and steel exported, the values, as compared with quantities, were as under, for the eleven months ended 30th November:—

Year.	Quantities. Tons.	Values. £	Average value per ton to nearest decimal. £
1887	1,819,188	16,118,679	8·8
1886	1,446,275	14,506,965	10·0
Increase in 1887	372,913	1,611,714	

The first impression likely to be conveyed by these figures is that the iron and steel works have been working for lower prices, and presumably also for lower profits, in 1887 than in 1886. This is, indeed, likely to have been the case, but it need not necessarily be so. Everything depends upon the proportions of the different descriptions of iron exported. If the exports for 1886 embraced a considerably larger proportion of iron or steel that cost a high price to produce, and if those for 1887 included a larger proportion of cheaply produced iron, the result might be a larger profit in 1887, concurrently with a lower average realised value. It is here that the Board of Trade returns are defective in the information they supply. But they do show, unmistakeably, that the money received for our iron and steel exports, relatively to quantity, fell considerably short in 1887 of what was similarly received in 1886. It is said that threatened men live long. This aphorism is peculiarly applicable to the case of the tin plate industry, for notwithstanding all the efforts of the United States and Germany to oust our tin plate makers, they have sent abroad in 1887 a larger tonnage than in any previous year, although at unprecedentedly low prices.

LEAD, TIN, COPPER, AND OTHER METALS.

The improvement which has been noted in some other branches of the mineral and metal trades, has extended in a minor degree to lead, the imports of which for the first eleven months of the current year were nearly 8000 tons in excess of those of the corresponding period of 1886. There has also been an increase of nearly 2400 tons in the exports. The output of metallic lead in the United Kingdom during 1887 is not yet ascertainable; but for the year 1886 it amounted to 39,482 tons, being an increase of nearly 2000 tons on the production of the previous year. The tendency is to become more and more dependent upon foreign sources of supply, and this tendency appears to have been quite accentuated during the past year. Prices over the year have not varied greatly from those of 1886. The average import price for 1887 was £12·5 per ton, as compared with £12·7 in 1886, and £11·2 in each of the two preceding years. The prices of 1884-85 were, however, the lowest in the history of the trade. Indeed, the average price over the seven years ending with and including 1878 was more than £20 per ton, or about double the average of recent years. This enormous difference has, of course, been chiefly due to the opening up of foreign sources of supply, which have had the effect of practically shutting up a number of English mines, and on which we must apparently more largely depend in the future.

As measured by volume, the tin trade has not been so active during 1887 as in the immediately preceding years. The imports for the first eleven months of the year amounted to 442,155cwt., as compared with 445,220cwt. in 1886, and 480,525cwt. for 1885, in the corresponding periods. Leaving the recent sudden rise of the market out of account, prices of imported tin have been higher in 1887, averaging £5·3 per cwt., as against £4·81 in 1886, and £4·28 in 1885. The tin trade, like those of lead and copper, has become mainly dependent on foreign supplies. In 1878 the production of tin in the United Kingdom amounted to 10,106 tons, and the imports were 16,644 tons. In 1886, however, the home production was only 9312 tons, while the imports were 24,026 tons. The effect of the higher price of imported tin in 1887 has, of course, been unfavourable to the tin plate industry, the more so as the prices of tin plates have been lower than in the two preceding years, when tin was cheaper. There has, however, been a larger export of unwrought tin in 1887 than in either of the two previous years. The average price of the exported tin in 1887 was £5·0 in 1886, and £4·4 in 1885. The fact that England is so largely dependent upon foreign tin supplies alters our relative position as a tin-plate producing country, and it is used by Americans as an argument for renewed efforts to establish in the United States a tin-plate industry, in order to become independent of English supplies of that material. The prices of imported tin do not, however, diminish. They are, on the contrary, considerably higher than they were a few years ago.

There has been a good deal more fluctuation in the copper trade during 1887 than in any of the other metals. The imports of copper ore have been rather larger than in 1886, but about 12,000 tons less than in 1885. Of regulus and precipitate, the same story is to be told, the imports having been 69,399 tons for the first eleven months of 1887, as against 65,166 tons in the same period of 1886, and 79,617 tons in the first eleven months of 1885. There has, however, been a remarkable decline in the imports of worked and unworked copper, which were 27,040 tons in 1887, 40,692 tons in 1886, and 39,317 tons in 1885. The average price of copper was, during the first eleven months of 1887, £42·2, as compared with £42·3 in 1886, and £46·9 in 1885. In all three years, however, prices have been, on the average, abnormally low. Up to 1883, the price of copper never fell below £60 per ton; and in 1872, it was as high as £92. It has within the last four years fallen to less than one-half its former average price. It has been the same with copper ores, the imports of which averaged £6·7 per ton in 1887, as compared with £6·85 in 1886, and £11·10 in 1884, while between 1872 and 1876 the price varied from £17·2 to £12·4 per ton. The export trade in copper has been better in 1887 than in either of the two previous years; but not so with mixed or yellow metals. India continues to be the best market for our copper products, and France has largely increased her consumption in 1887. The total value of our exports of copper in the first eleven months of 1887 was £2,404,000, as compared with £2,366,000 in 1886, and £2,815,000 in 1885. The output of fine copper from British ores is rapidly falling. It was over 5000 tons a year until 1873; but since that time it has gradually diminished, until in 1887 it was only 1471 tons, valued at £65,463. Copper is, in this respect, following the same course as lead and zinc, the production of the latter from British ores having fallen from its maximum yield of 16,130 tons in 1882, valued at over £286,000, to 8989 tons, valued at only £141,000, in 1886. The prices of zinc, have thus also suffered serious reduction. Between 1872 and 1877 crude zinc varied from £20 to £23 per ton. Over the last four years, it has fluctuated between £14 and £15. The imports of crude zinc in 1887 were larger than in any previous year except 1885, when they were over 60,000 tons.

The following is a statement of prices in December of each of the last three years:—

	1887. Per ton.	1886. Per ton.	1885. Per ton.
Copper, Chili bars	£ 80 10 to —	£ 38 to 39 0	£ 40 0 to 41 0
Tin, English ingots	153 0 „ —	155 „ —	97 0 „ —
Lead, English pig	15 0 „ 15 10	12 „ 13 0	12 10 „ 12 15
Spelter, Silesian	19 0 „ 20 0	14 „ 14 10	14 10 „ 15 0
Antimony, regulus	45 0 „ 46 0	28 „ 30 0	34 0 „ 35 0

(To be continued.)

IMPORTS INTO SICILY.

Owing to the loss of a copy of the report of the British Consul at Palermo in the post, the statistics of the trade of Sicily for last year have only just been published by the Foreign Office. The principal imports from England were coal, iron, water pipes, tin plates, leather and raw hides, carpets, chemical products, machinery, linseed oil, copper, lead, zinc, coffee, biscuits, woollen, cotton, and jute goods, colours and varnishes, earthenware, and glass goods. There was a decrease in the importation of coal during the year of 16,312 tons, representing on arrival a value of £23,208, as compared with 1885; but the imports of iron and iron goods, metals, and machinery were greater. Iron and iron goods show an increase of 41,068 tons, of a value of £28,777. The greater part of the imports of iron came from Liverpool, and of water pipes from Glasgow. The British percentage is, however, falling off, owing to Belgian competition. The imports of machinery, which largely consist of sewing machines, have slightly increased. The chemical products imported consist chiefly of sulphate of quinine from England and France; citrate of magnesia, mainly from Milan; sulphuric, nitric, citric, and other acids, chiefly from Newcastle; soda, in iron drums, potash, sal-ammoniac, sulphate of copper, and chloride of lime. Germany is a strong competitor in this branch of business. Out of chemical imports of the value of £16,868, products to the value of £6,097 were derived from England. As regards tissues of all kinds, with the exception of silk goods, there was a slight general decrease, and English manufactures specially show a falling off, though they once had a monopoly of the market. The Consul states that the competition of Italian and German goods is driving English textiles out of the market, and that the hardware trade has passed entirely into German hands.

IRRIGATING MACHINERY ON THE PACIFIC COAST.*

In offering the present paper to the Institution of Mechanical Engineers the author does so with a tolerably complete knowledge of the very advanced practice in England in this class of machinery; and his purpose is mainly to explain the differences that have been called for by local circumstances in California.

Character of the Country.—The western or Pacific slope of the Sierra Nevada or coast range of mountains in California is very abrupt, the crests of the range being so near that the snow is visible from the coast during the whole year. Hundreds of streams cross this narrow country, falling either direct into the Pacific Ocean or into the great basin formed by the Sacramento and San Joaquin rivers. These two rivers, the largest in California, run in opposite directions, nearly parallel with the coast, and meet at the Bay of San Francisco, forming a continuous valley 400 miles long and from 50 to 100 miles wide. The small streams for the most part are fed by melting snow in the summer; and every gulch or cañon has its rivulet or brook. They increase in volume until they pass into or through the hills at the foot of the mountain range; and there, unless of considerable size, they may wholly disappear in summer by percolation through the silt or by evaporation. Streams exposed to the torrid air which in summer sweeps across the sand deserts of southern California are dried up with wonderful rapidity. The evaporation from Salt Lake, exposed to the same dry wind, is sometimes equal to half an inch per day, or 64 million tons of water. Notwithstanding this great loss by evaporation, the quantity of water falling into the ocean on the coast of California has been estimated at 100 million cubic feet or 2¾ million tons per minute, enough if distributed properly to irrigate 25,000 square miles. The Pacific coast in California may be said to consist of a mountain slope, fissured everywhere by water; and of alluvial plains formed by the sediment deposited from the water, which varies from coarse gravel and sand to fine silt, as the velocity and volume of the water courses have determined. Nearly the whole country is therefore underlaid with strata of sand and gravel, which afford water everywhere at various depths.

The need of irrigation arises from three causes: the lack of rain, which in summer ceases wholly along the coast; the want of surface water; and the free percolation into the sand beneath. The area requiring irrigation comprises most of the land in the country, except the lowlying sedimentary plains near the mouths of the rivers, and around the Bay of San Francisco, where water reaches the surface by capillary saturation.

Water Training.—In the days of placer gold mining, a large part of the running water in the mountains and foot hills was collected in extensive ditches, flumes, and iron pipes; the water was as important as the gold, which could not be washed out without it. Placer mining is gone; but the ditches remain, most of the water now being required for the more permanent business of fruit growing and other kinds of agriculture. Perhaps no part of the world equally rugged and difficult of access has been so thoroughly explored and mapped as this. From the tops of the mountain ridge to the depths of the cañons there is scarcely an acre that has escaped the search for gold and silver. The information thus acquired respecting the surface of the country was made use of as soon as agriculture began to receive attention; and the result is that nearly all land is now occupied upon which water can be led, not only by training small mountain streams, but also by leading long canals, or ditches as they are called, from the rivers; until at the present time, or when works now in hand are completed, the only remaining resource for getting water will be by lifting it from the rivers or the gravel strata by machinery.

Character of the Machinery required.—The standard methods of raising water for irrigation and drainage, commonly adopted in the Netherlands and elsewhere, would not apply on the Pacific coast. Permanent foundations are wanting; a number of small separate pumping stations, widely distributed, are required, instead of a few large establishments centrally situated; and a high efficiency is essential in the machinery employed, because of the high cost of fuel, coals of indifferent quality being worth from 30s. to 40s. a ton. For raising 420,000 gallons per hour from 6ft. to 10ft. high the cost of the machinery is from £500 to £600. For raising 1,000,000 gallons per hour from 10ft. to 14ft. high the cost is from £800 to £1,000, including engines, boilers, pipes, and framing. This must account for the light sections and other scant proportions that will be observed in the drawings; material enhanced in value 40 to 50 per cent. by tariff taxes is of course used sparingly. An efficiency of 65 to 70 per cent. is attained in most cases when the head or lift is between 8ft. and 16ft. For pumping from deeper wells the machinery is much more expensive, in proportion to the quantity of water raised, both because of the greater length of the driving connections to the pumps, which are placed in the bottom of pits in order to be within suction distance of the water, and also because of the greater strength required in all parts to stand the speed and pressure.

Fruit farms, on account of the labour and attention they require, are limited in size; and irrigating machinery must come within moderate limits of cost. Where the water is drawn from the gravel, concentration of pumping is out of the question. Percolation is not free enough to admit of large quantities being raised at one point and distributed; and even if this were possible, adjacent wells would be robbed, and litigation might ensue. In some experiments at San José, California, during the year 1885, it was found that, in drawing 15,000 gallons per hour from two artesian wells of 10in. diam. and 200ft. depth, neighbouring wells of distances of from two to six hundred yards were lowered. In this instance the water rose naturally to 2½ft. above the surface of the ground at the wells, and was lowered only 6ft. by drawing 15,000 gallons per hour. The wells here referred to, and indeed nearly all wells in irrigated districts, are tubes of sheet iron from 6in. to 14in. diam., sunk by forcing, the earth being removed through the interior of the tubes. In the broad alluvial plains along the Sacramento river, and especially in places near to its banks, percolation is so rapid that some attempt has been made at concentration of pumping plants. One well of 40ft. diam. and 16ft. depth, having an infiltrating surface of 1000 sq. ft. to 1200 sq. ft., yields 180,000 gallons per hour; and others of smaller infiltrating area yield a proportionate quantity. But these are in places where the water bearing strata are much thicker than usual, the gravel coarse, and the saturation greater than in most other parts of the country.

Early Irrigating Machinery.—One of the earliest appliances for raising water in California was the Chinese pump, illustrated in Fig. 1, which consists of an endless band travelling round pulleys at top and bottom of a moderate slope, and carrying a series of wooden floats or cross bars fixed on its outer face; the under span ascending through an open trough carries up water from a ditch or pit and delivers it into a launder or flume at top. The endless bands are sometimes made of india-rubber or cotton canvas; but more commonly consist of a pair of ropes, upon which the cross bars, having their ends split, are clamped at regular intervals by means of screws. It is a very cheap contrivance, and for low lifts is still employed to a considerable extent by the Chinese and Italians; it was doubtless introduced into California by the Chinese in imitation of similar pumps extensively used in China for raising water from the canals, where the lift is only a few feet. For slopes not steeper than 20 degrees, and lifts of only from 3ft. to 6ft., it is found to be very economical in cost of working, and is said to be capable of high duty when the wooden floats or cross bars are so arranged and proportioned as to render the rising span nearly buoyant in the water, and especially when the inside of the trough is lined with metal to diminish the friction. For irrigation these pumps are commonly driven by horses, and for other purposes are employed only temporarily; and so far as the writer knows, no experiments have been made to determine their real efficiency. For lifts exceeding 10ft. and slopes steeper than 30 degrees, the friction and leakage render them unsuitable; and their use is being abandoned as better methods are introduced.

Tube Well Pumps.—These pumps, or the method of constructing them, grew out of the oil well experience in the Atlantic States. The tubes or barrels, which constitute both well and uptake, are made of galvanised iron, from No. 18 to No. 14 B.W.G., or 0·050in. to 0·085in. thick, with the longitudinal seams riveted and soldered together throughout. They are made from 6in. to 14in. in diameter, and are sunk to depths varying from 100ft. to 200ft., sometimes more when pure water is wanted. The water rises in the wells to heights varying with different seasons, and in some cases overflows at the surface, as in the well at San José already mentioned. The pumps are placed at different depths accordingly. For irrigation the wells are generally arranged in a quadrangle. These crude looking pumps are much more effective and economical in their working than would be supposed. The pump rods are of wood, their section being equal to half the area of the working barrel; consequently in both the up and down stroke the delivery is equal to half the capacity of the barrel. In effect therefore the pumps are double acting, with only one set of valves, and the load is in a measure equalised between the up and down strokes; they correspond with the ordinary bucket and plunger arrangement common in mining districts. The working barrel is either a brass casting bored out, or made of drawn brass tube. The foot valve at bottom is inserted from the top, and can be drawn out and replaced without trouble, after the pump rod and bucket valve have been removed. The two tube wells of 10in. diam. at San José, already mentioned, were put down by contract at 5s. per foot for the first 100ft., including everything. For a second 100ft. the cost per foot would be something more, not exceeding 50 per cent. extra, and generally less, according to the nature of the ground to be sunk through. Wells from 7in. to 8in. diam., and not exceeding 150ft. deep, cost from 4s. to 6s. per foot, including galvanised tubing inserted ready for use. Much depends of course on the nature of the ground, and if boulders are met with the whole work may be lost. It is not easy to withdraw the tubes, and in case of obstruction they are generally abandoned. A serious impediment to the use of these pumps is the wear of their valves or leathers, which are soon destroyed by sand and gravel. To renew them, the pump rods of 50ft. to 100ft. length have first to be removed by drawing them up and disconnecting the sections one at a time. As the rods are long, heavy, and inconvenient to handle, half a day's time of two men may be required to replace a leather which will not last twenty-four hours after it is inserted. Accordingly for pumping from the sand and gravel strata the author is of opinion that no machinery which involves close fitting pistons or sliding joints of any kind exposed to the water can ever succeed in California.

Centrifugal Pumps.—The destruction of pistons by the sand and gravel has led to the adoption of centrifugal pumps. In these, with their constant and rapid flow, the sound of the gravel striking against the elbows and sides of the pipes can be heard distinctly. A pile of gravel and coarse sand soon accumulates wherever the speed of the discharged water is slow enough to allow of precipitation; and the wonder is what supplies the displacement thus caused at the bottom of the wells. Elsewhere it has not been common to recommend centrifugal pumps for high lifts, and they have been considered less economical than piston pumps; but the opinions hitherto entertained regarding them have been much modified by the experience of their working in California. A head of 100ft. however, for a centrifugal pump to work against, is a very different thing from a head of only 10ft. When the head exceeds 40ft., efficiency declines rapidly, but not to such an extent as to outweigh the great economic advantages of centrifugal pumps for heads up to 100ft. or even more. For lifting water from the gravel strata in California, four kinds of centrifugal pumps have been employed, viz.: firstly, the common make, with open vanes revolving in a plain volute casing; secondly, wheels with shielded or encased vanes, the water being drawn in at the centre and discharged from the circumference; thirdly, compound pumps with two or more wheels acting in succession upon the water during its passage through the pump; and fourthly, balanced pumps receiving the water at one side, whence it is deflected in an easy curve to the circumference by a conical disc on which are formed the vanes. These various forms of the centrifugal pump may be regarded as phases of development, adapted in some cases for particular objects, but generally reverting from enclosed discs, compound or double wheels, and other features, back to the original simple form of the first pumps in use prior to 1820. The wheels with encased vanes, for example, have been a feature of first practice with most prominent makers. These wheels were made in America as early as 1831, mainly with the object of partly avoiding side thrust when a single inlet was employed.

Centrifugal Pumps with Open Vanes.—These are employed for lifts up to 30ft., and are usually arranged, as shown in Fig. 2, at the bottom of rectangular pits sunk to the depth required for bringing the pumps within suction distance of the water. The pits have often to be sunk 50ft. or more below the surface, and are usually 10ft. to 12ft. long, and 4ft. to 6ft. wide. The sides are lined with planks of redwood (*sequoia*), which is very durable under exposure in such situations. Two or more tube wells T are sunk from 50ft. to 150ft. below the bottom of the pit, and in them are placed suction pipes S, connected by bends at top to the upper side of the horizontal pump casing, as shown in the illustration. This mode of connection is adopted simply for convenience in the present case, in which there is no upward thrust; but for a different and more important purpose in other cases to be described presently. The pump P is driven by a vertical shaft, which is mounted in pivoted bearings B, each having a supporting collar for carrying the weight of the shaft and pump wheel. The compression couplings C, for connecting the several lengths of which the shaft is made up, are so constructed as to be almost instantly loosened or removed. These couplings were introduced in England a short time ago by the writer, and have given evidence of superiority over the more intricate modifications that have preceded them. The uptake or rising main U from the pump is of galvanised iron, and preferably two to three times as large in area as the delivery nozzle on the pump. The pumps are charged in several ways, always from the top of the pit. In Fig. 2 is shown a steam ejector at E, with a small pipe running down to the pump. Air pumps are sometimes used. Charging with water is out of the question, because foot valves are no longer employed; it was found that the rapidly entering water, loaded with sand and gravel, cut away the valves like the sand blast process; and there is no room in the well, as there is above, for making flap valves that swing clear of the current. Single acting engines have been found most suitable for driving these pumps, and are now extensively adopted for the purpose, being connected with the top of the vertical pump shaft by a band, as shown in Fig. 2. For some of the earliest pumps horizontal driving shafts were employed, with bands extending down the pit from a shaft at the top to the pump at the bottom; but the weight of the bands, the danger to anyone descending the pit, and the delay caused by breaking, rendered the plan undesirable, and it has given way to vertical driving shafts. One of the first experiments in deep pumping with a centrifugal pump was made in a case where the water stood at 70ft. below the surface; and when it had become lowered by pumping, the lift was 74ft. The pump was a compound one, driven at 900 revolutions a minute, raising 10,000 gallons an hour. The pit was only 3½ft. square, and the pump was fixed at 60ft. below the surface. A band passing down the pit was employed for driving; but the difficulties attending its use were such as to direct attention to other and safer methods of transmitting power in deep pits.

Centrifugal Pumps with Shrouded or Enclosed Vanes.—Nearly all makers of centrifugal pumps in California and elsewhere have at first followed Sir Henry Bessemer's plan of more than thirty years ago, employing shrouded wheels, in which the sides of the vanes are attached to two enclosing discs that revolve with them. The difference is very great between a wheel or runner constructed in this manner, with closed sides, and an open wheel without enclosing discs attached to the vanes. With the shrouded wheel a water tight joint must be maintained all round the inlet orifice; otherwise the water would only circulate through the pump, passing from the circumference back to the inlet. Such leakage is increased by the pressure, which at all points on the sides of the wheels is the same as in the discharge pipe or at the discharge orifices of the wheels. The skin friction of the water seems to be less with a shrouded wheel; the water instead of being driven round in contact with the sides of the stationary casing, flows through the wheels as it does through the pipes, without any greater skin friction in passing through the wheel than for an equal distance in the pipes. On the other hand, however, there is the skin friction of the outside of the wheel itself, and this has been found to be diminished by having a considerable thickness of water intervening between the outside of the revolving wheel and the inside of the stationary casing. In the pump shown in Fig. 3, there is only a very narrow clearance space at the sides of the wheel; but here unusual care has been taken in construction, the wheel being turned and made perfectly true after being keyed on the spindle. The resistance greatly increases if the wheels are not perfectly true, but up to the present time the data respecting friction in such cases are meagre. Experiments now being made in the University of California it is hoped will before long afford useful facts respecting the friction of submerged bodies revolving at high speed. As the water enters through one side only of the wheel, it causes a thrust in that direction, which is equivalent not to the force of suction only, as is generally supposed, but to the whole duty performed, including both suction and delivery. The pump being inverted, with the suction inlet at the top, the entering water flows downwards, and the reactive force is consequently upwards. The upward thrust, which, in most cases, would be objectionable, is here turned to practical account for supporting the weight of the vertical driving shaft and the pump wheel. The plan of inverting the pump so that the suction enters at the top was introduced in California by the writer in the latter part of 1883, and he believes it will be of great importance in future, because of the difficulty of supporting the vertical driving shafts by other means in the deeper pits. In the case of one pump, completed a short time ago, the weight of the shaft and its attachments was nearly 2000lb. The shaft was of steel, 2¼in. diam., and ran at 600 revolutions a minute. The upward thrust was sufficient to carry this shaft, together with some additional weight which was found necessary. The lift was 90ft., inlet of pump 10in. diam., throat of discharge 5in. diam., uptake pipe 10in. diam. This problem of thrust upon enclosed wheels taking water at one side is an intricate one. If the rear side of the wheel is exposed, as is common, to a pressure

equal to the discharge, the thrust is the inlet area multiplied by the discharge pressure. If the wheel is shrouded on one side only, the thrust will be equal to the whole area of the wheel multiplied by the discharge pressure. At starting there is of course no upward thrust until the pump is charged. Provision is therefore made at C for carrying the shaft on collars, which are already required for steadying the revolving wheel laterally in the pump casing, and are so arranged as to support the shaft vertically for a short time, unassisted by the water thrust. The collars are screwed upon the shaft, and several thin washers of steel are inserted between them and the seat which carries them. They run in a pool of oil, or rather oil and water, because there is generally a small pipe leading a little water back from the discharge pipe to the thrust box C. The joint thus formed seals the pump, taking the place of a packing gland. It was with some misgivings that the writer first ventured to substitute this contrivance for a packing gland on the suction side of a pump; but thus far it seems quite as reliable, and requires no care or adjustment. The suction pipes S S are shown as commonly arranged, for branches leading in from right and left; their area is equal to that of a number of branch pipes.

Compound Centrifugal Pumps.—Two of the main problems to be dealt with in applying centrifugal pumps to high lifts are how far the impact or mechanical push of the vanes may be disregarded as a factor in the pump's duty, and how the bearings and driving gearing may be maintained in proper order at the high speed required. Practically the speed at which the pump should be driven increases as the square of the height of lift. As the pits are too narrow to admit pumps with volute casing and with a single wheel large enough to attain the required speed, the pumps have to be compounded, as shown in Fig. 4, so as to reduce the speed of rotation and diminish the size of the wheels and casing. In the compound pump here shown with two revolving wheels R, the main casing is made in five parts, consisting of three hoops or rings and two intervening diaphragm plates, all secured together by external bolts. The driving shaft from the top of the pit is coupled to the pump spindle at C. A charging pipe is carried down from the top of the pit. The foot of the delivery main M is surrounded by an annular air vessel A. The water is drawn by suction into the top chamber T, whence it passes downwards through the two wheels or runners R, and out through the discharge chamber D, the delivery valve V, and the rising main M. The two shrouded wheels have each five curved vanes. Curved throat pieces and tangential tips to the vanes are found in such cases to be of practical value so far only as they tend to obviate friction and consequent slight loss of power. The diaphragm above the upper runner is a plain flat plate; but the intermediate diaphragm between the two runners is made with fixed guide blades on its upper side, for leading the water back from the circumference of the upper wheel to the central inlet into the lower. The delivery valve V is arranged to swing clear of the ascending column of water; the area of passage is here contracted, and determines the pump's capacity. In all other parts the area of passage is made much larger. The seat of the delivery valve V is raised so as to leave an annular space all round it, for catching any gravel deposited in the valve chamber; this space is commonly made much larger than shown in the illustration. The bottom bearing of the pump spindle at B, Fig. 4, is simply a hole bored in the base plate. There is no strain upon it when the wheels are carefully balanced. It is of course exposed to sand and gravel, but these do not seem to have much effect upon bearings of steel running in cast iron; either the sand is at once pulverised and washed out, or in some other way attrition is prevented. Similarly the throats of the inlet orifices in the revolving wheels do not seem to wear after they have ground themselves out of contact.

Triple Centrifugal Pump.—In Fig. 5 is shown a vertical section of a triple pump designed for the permanent duty of raising 3,000,000 gallons of water per day through a lift of 70ft. for a town supply in California. The suction pipe S is here connected with the bottom of the pump casing, and the water entering at A ascends through an inlet orifice in the under side of the bottom runner, from which it is delivered to the top of the pump, and thence passes downwards through the two upper runners, and from the lower of them to the delivery pipe D. Two of the three wheels balance each other in vertical thrust, and the upward thrust of the third will be sufficient to support the steel driving shaft of 2½in. diam., together with all its mountings, the whole weighing 1800lb. to 2000lb. In one instance the working of a compound centrifugal pump has been interfered with by the liberation of carbonic acid gas in the suction pipe, owing to the vacuum of 6lb. or 8lb. per square inch below the atmosphere. The difficulty is easily overcome by providing vent for the gas at the highest point in the discharge chambers.

Balanced Pump with Single Lateral Inlet.—In Figs. 6 and 7 is shown the construction adopted by the author for pumps with a single inlet at one side, a form most suitable for the requirements of the Pacific coast, and essential in many cases. The drawing shows a pump of 12in. bore arranged for a head of 30ft. The wheel consists of a curved disc D, shaped so as to deflect the water gradually from the centre to the circumference. On the face of the disc are formed the vanes U and V of unequal area, On the back of the disc are also vanes N. Holes C are made through the disc, so that any water passing around the circumference may circulate in this way. An equal or nearly equal centrifugal action is thus set up on each side of the disc, and there is no axial thrust, the pump being balanced in the same way as though there were double inlets, one at each side. In this arrangement the suction pipe is easily removed, and can be hoisted vertically clear of the pump. The water passages are also more free, and of large area until the disc is reached. In order to guard the spindle bearings from sand and grit, the packing is placed at P inside the main bearings B, which act also as glands for compressing the packing. This arrangement is now employed in all the various modifications of centrifugal pumps from the author's designs, and in working permits no leak of either air or water; and the packing seldom needs renewal. The pumps are characterised by great steadiness of running, and an absence of the pulsation or jar common with free or open vanes or with enclosed discs. Such jar is often caused by an obtuse or imperfectly formed throat piece at T, especially with enclosed discs, the radial flow being interrupted at that point.

LOGGING IN CANADA.

I.

In England, where the trade in native timber is so limited as to be hardly worth consideration, it is difficult to realise the wholesale manner in which the felling of trees and subsequent handling of logs is carried on in the great continent of North America. Compared with this industry, whether in Canada or the United States, the timber business in what we are in the habit of calling "timber growing" countries in Europe is quite insignificant. The great centre of the logging industry is the country surrounding the lakes Huron and Superior, which form part of the boundary line between Canada and the United States. On the Canadian side is situated the province of Ontario, and on the opposite side is the state of Michigan. The system of "logging," being the name by which the trade is generally known, is much the same in both countries. The statistics and details, however, given in these articles will mostly relate to Canada, though in cases of special interest reference will also be made to the United States.

It is stated that the exports of timber produce from Canada alone average an annual value of £6,000,000, by far the greater proportion of which represents pine. This sum, however, only represents about three-fifths of the total output of the forests, as the remaining two-fifths are required for home use. The demand is still on the increase, especially for the latter purpose, as the population of Canada is rapidly multiplying, both from immigration and natural causes. The supply of timber is, however, equally rapidly decreasing; so much so, that it is considered by many that within a few years these pine forests, which until recently were looked upon as inexhaustible, will be entirely obliterated. Opinions differ very much as to what quantity of pine still remains, and as it is most difficult to assess standing timber correctly, this difference of opinion is easily accounted for. We give herewith the estimates of two authorities on this subject. At the Forestry Convention in Montreal, in 1882, Mr. Little stated that in the whole of Canada there remained ten thousand million feet of pine, and that felling was going on at the rate of one thousand million feet annually. From these figures it would appear that there was enough at that time to last ten years, leaving now only a five years' supply. Professor Macoum, botanist to the Canadian Government, however, looks on the matter in a very different light, giving us to understand that the supply is not so limited, and that, even if the "white" pine does fail, there are other qualities of pine sufficiently good to replace it in the European market. We extract the following from his speech at the Conference on Colonial Timber which took place in London last year: "Many of our men say that the white pine, known as the yellow pine here, is getting scarce; but we think the Douglas pine, which is not confined to British Columbia, will take its place. It is found all through the Rocky and Selkirk mountains right down to the Pacific coast, and I know that it grows five degrees to the north, as I myself found it from latitude 49 to latitude 55, so that you see the supply is not limited; and when our yellow pine gets so scarce that it becomes dear you will have to take this in its place. The trees will produce a great quantity of timber, and one tree that was cut down was 90ft. long, the large end being just 13in. across and the small 7in., so that in ninety feet the taper was precisely six inches. . . . When we Canadians talk about supplying woods, we are prepared to supply any quantity—not for a few years only, but for years and years."

One thing, however, is very certain, and that is no matter when the date may be that these forests will cease to exist, it must come sooner or later, unless prompt and

Digitized by Google

systematic re-planting is at once undertaken; and the various governments of the provinces, urged by practical men, are now awakening to that fact, and are in many cases offering great facilities for its accomplishment. The disappearance of the forests would not only be an immense loss to the Dominion on account of the value of the timber, but also on account of the lamentable effect that such a state of things would necessarily have on the climate, and consequently on both health and agriculture. For statistics clearly show that the wholesale destruction of trees has the effect of producing both drought and floods, with their attendant evils.

Although the lumberman and the agricultural settler are responsible to a great extent for the thinning of the forests, the principal element of destruction has hitherto been fire. Terrible conflagrations have from time to time played enormous havoc with vast tracts of valuable timber, destroying everything in their path, and leaving behind them a wilderness of charred débris; so scorching up all vegetable life, and the soil itself, as to make it impossible for anything to grow there for years to come. Mr. Thistle, a lumberman and surveyor of great experience, gave it as his opinion that ten times as many trees had been destroyed by fire as by the axe; and this can be readily understood when it is pointed out that fires extending over some hundreds of square miles were at one time of no unusual occurrence. The largest fire that has ever been known in Canada, and probably in the world, took place in October, 1825, in the neighbourhood of the Miramichi River, in the province of New Brunswick, and extended over a total length of 220 to 230 miles, and a vast breadth, destroying not only the forests and many hundreds of lives, but also several towns, including Douglastown and Newcastle, and leaving 2000 people absolutely destitute. From the above it will be seen that precautions against fire are at least as important as the re-planting of trees, and it is a satisfaction to know that stringent regulations are now in force in most of the provinces, and that special watchers are appointed to see to the proper carrying out of them.

A reckless waste of wood characterised the work of the early lumberman, and it is estimated that he has been in the habit of leaving behind him as much serviceable wood as he has taken away, using only such parts of the tree as could be got at with the least work. This is not only wasteful, but also a source of danger, as the vast amount of dry chips, branches, and the rejected timber afford excellent food for the flames if a fire should break out in the locality. Another source of waste and danger, not so prevalent nowadays, was the amount of timber felled by the road makers, and left to rot.

As before stated, the province of Ontario is the principal lumber district of Canada; in fact, it is estimated that it contains more than one-third of the "white" pine in the Dominion. It covers an area of 200,000 square miles, being more than half as much again as the whole of the British Isles. Its climate is very healthy, though the thermometer varies to a great extent, viz., from many degrees below zero to upwards of 90°F. It is difficult to strike a mean temperature which will give a correct idea of the whole province, as the temperature varies greatly with locality; but the official reading for the last forty-four years is 44°18F. Within the memory of living man the whole of Ontario was one vast virgin forest; but it is doubtful whether one-third of the area is under timber at the present day. Until recently lumbering was its principal industry; but now, although this trade is increasing, agriculture has surpassed it, progressing in a greater degree owing to the continuing influx of immigrants, and the favourable properties of the land for farming. The lumber trade in this province is estimated to provide employment for a population numbering 100,000, directly and indirectly, about 20,000 of whom represent the men actually employed in the forest. The revenue from this industry amounts to an annual sum of nearly half a million dollars, and is derived in the following manner: The Government allots the forest land, sometimes by private sale, but more often by auction, and the purchaser of the tract or "limit," as it is usually called, has the right of felling the timber upon it, paying a further tax of so much per thousand feet of wood when the trees have been converted into logs, in addition to a ground rent of $2 per square mile during his occupancy, the Government retaining the ownership of the land, so that in reality the so-called "purchaser" is, more properly speaking, merely the licensee.

Logging begins when the saw mills close—that is to say, towards the end of September the various gangs find their way into the forests to the scene of their respective labours. The number of hands in a gang varies very much; but as a rule they consist of from thirty to sixty or seventy men. Having reached the "limit," the foreman selects a suitable spot for the camp, and all hands proceed to clear it and erect the necessary buildings. These shanties are seldom used for more than one season, as the gangs work further into the forest each year, and consequently the buildings, though substantial, are of the rudest construction. Each camp is

LOGGING IN CANADA.

FIG. 1.—A LOGGING SHANTY IN WINTER.

composed of four or five different buildings, viz., dwelling hut, stables, blacksmith's shop, granary, and shed for sleighs, which latter must be kept under cover as much as possible, on account of the heavy snowfall, which in this district averages as much as 70in. in the year, the snow commencing to fall early in October and not disappearing for six months. Strange as it may appear at first sight to Englishmen, who look on snow as a serious impediment to traffic and business generally, in Canada its appearance is looked forward to by all, whether by the pleasure seeker of the city, to whom it means an incessant round of gaiety, or by the lumberman, who regards it as the highway by which his supplies for the forthcoming season are to be conveyed the first step on their journey. Indeed, were it not for the smooth surface afforded by the frozen snow, often 3ft. deep, it would be well nigh impracticable to convey the rough logs to the river down which they are to be floated. Fig. 1, above, represents a logging shanty in winter. The buildings, as is natural, are constructed entirely of logs, even to the roofs. The dwelling hut is rectangular, and consists of one compartment, round which the sleeping bunks of the men are ranged, a box being placed at the foot of each, containing the effects of the occupant. A huge log fire burns day and night in the centre of the room, not only serving to heat it and cook the victuals, but also affording the only light to the interior, there being no windows whatever. The smoke escapes through a conical chimney in the roof. As will be readily understood, the supply of provisions, though plentiful, is anything but varied, consisting usually of salt pork or beef, flour, and tea, no intoxicants whatever being allowed. The supplies are brought in as often as practicable on sleighs from the nearest station. The men employed are mostly French Canadians, who, though without remarkable physique, are tough and wiry. They by no means strike the observer as possessing a vast amount of intelligence, with the exception of the leading men, who, holding a responsible position, must be capable of using their heads as well as their hands. A logging gang is generally made up somewhat on the following lines: One foreman, who has entire control of the work and camp; one "culler" appointed by the Government, whose duty it is to measure every log cut, and who is bound by oath to render a correct account of it to the authorities, for the assessment of the timber dues (it is he who inspects and passes the good timber, rejecting the unsound by marking it with a "cull," or red cross, on the butt end of the log); eight or ten log makers, who fell the trees, cross cut them to the standard lengths, and "butt" or trim the ends; half a dozen or so teamsters for conveying the logs along the side tracks in the forest to the main road leading to the river; a certain number of chainers, who, with the aid of horses and tackle, drag the logs from where they are felled to the sleighs; a corresponding number of sloop loaders; a blacksmith; and a cook, who is assisted by a "chore boy," whose duty it is also to collect fire wood and make himself generally useful about the shanty. For conveying the logs down the main road to the river (often a considerable distance) another gang of teamsters is frequently employed, working by contract, independent of the logging gang, and occupying a separate shanty.

The wages paid to the various workers in a logging gang may be rated as follows: Foreman, $1,000 per annum; log makers, from $20 to $23 per month; teamsters, from $18 to $20 per month; general workers, $16 to $22 per month; blacksmith, $26 per month; and cook, $30 to $35 per month. None of the men are paid anything until the end of the season, as, food and lodging being found for them during the time they are in the forest, they have no opportunity of spending money. It will be seen that the cook, on whom the camp depends to a great degree for creature comforts, receives a wage somewhat in excess of what might be expected; but in spite of the fact that the meals are of the simplest description, and each one is an exact repetition of the former, his position is by no means a sinecure, cooking and baking, as he does, three meals a day for two or three score hungry men. The consumption of provisions in a shanty of fifty men, exclusive of the cost of conveying, may be valued at about $1,000 per month. The life of the logger while in the forest is almost devoid of recreation, as the nature of his work renders him disinclined for anything but repose at the end of the day. Sunday is kept by him as a day of rest in the most literal sense of the word, and Saturday night is the only time when any attempt is made to depart from the regular routine of work, food, and sleep. It is then that the more energetic indulge in a few songs and "breakdowns," to the accompaniment of a more or less melodious violin, if the camp can boast such a luxury, which is usually the case. It is interesting to note that although these men live together practically shut out from the world for about half the year, there are but few serious disagreements between them, law and order prevailing in the forest to perhaps a greater extent than in any densely populated city.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 3RD JANUARY, 1888.

THE IRON MARKET.—A feeling of relief pervades the iron market. With the last week of the old year the depressing influences under which we have so long suffered passed away, and we find ourselves at the commencement of 1888 amid circumstances favourable to a speedy return to prosperity. There is, perhaps, some exaggeration in the tone of hopefulness and confidence which now prevails; but a great improvement has certainly taken place, and there is abundant evidence of a tendency to further progress. A steady revival of business throughout the country, combined with the influence of a powerfal combination on the part of the manufacturers, has compelled the merchants of Paris to change their attitude, and there is no longer cause to complain of an undercutting trade. There is a manifest desire to acknowledge a community of interests, and manufacturers and merchants are now acting in concert. An agreement was come to a few days ago to advance prices 4s. a ton, making bars £5. 12s. and joists £5. 4s. In spite of the large business of the last three months, stocks in Paris are still heavy. The amount on hand is estimated at 70,000 tons, of which 67,000 tons are held by the merchants. Old rails sell well at 64s. The reality of the revival is shown by the activity which has for some weeks past characterised the crude iron trade of the Meurthe-et-Moselle. At this time last year there were stocks on hand amounting to 100,000 tons. Now there is not a ton remaining, and the demand exceeds the production. Prices of pig iron are consequently rising, and as coke has this week further advanced, the upward movement will be accentuated. The latest reports from the chief centres of industry are very encouraging. The present week will be a dull one on account of the New Year holidays and stocktaking, but these ended, we may hope to witness a rapid expansion of trade.

THE METAL MARKET.—Some of the parties whom I mentioned last week as members of the syndicate formed to keep up the price of copper have publicly denied their participation in that compact; but it is worthy of note that the denial was not given till a general shout of indignation was uttered by the Press, and angry demands were made for legal action against the offenders, who, it seems, are amenable to the law for "rigs" of this sort. This week the price of copper has further advanced to £85. 10s. Business in tin has been very quiet, but prices remain firm. Lead has given way slightly, the latest quotations being £16 a ton. Spelter continues to rise slowly in price, and is likely to go considerably higher, the demand for galvanising purposes being very strong and stocks low.

THE FOREIGN TRADE OF FRANCE.—The foreign trade for the later months of 1887 compares unfavourably with that of 1886. The value of the imports in November amounted to 376,423 million francs against 363,423 millions in the same month of last year, the increase being chiefly in food stuffs. The exports, which have fallen off considerably in manufactured goods, are valued at 302,253 millions against 328,002 millions in November of 1886. For the trade of the eleven months ending with November the value of the imports is 3,805,560 million francs against 3,766,392 millions in the corresponding period of 1886. The value of the exports for the same period is 2,980,096 millions against 2,934,002 millions last year.

A SCHOOL OF BREWING.—The project to establish a school of brewing at Paris is to be carried into effect. The Minister of Agriculture, by a decree dated the 24th December, has ordained the immediate creation of "Laboratory Schools of Brewing, Distilling, and Sugar Making," for which suitable buildings are to be erected on lands adjacent to the National Agronomic Institute, in the Rue Arbalès and the Rue Claude-Bernard.

THE EXHIBITION OF 1889.—Rumours are current here that notwithstanding official announcements, it is possible that the date of the opening of the International Exhibition will be postponed till 1890, in order to avoid the political complexion which it would have if it were to be held next year.

BERLIN, 2ND JANUARY, 1888.

THE IRON MARKET.—Owing to the holidays there has been some temporary dulness in most branches of the iron trade during the past week, but in fine sheets business has been fairly brisk. Heavy sheets, with the exception of boiler plates, have for some weeks been in but slight demand. Some good orders were secured for the home market before the holidays by steel makers, but there are not many orders for export on hand. The recent revival in prices is shown by the figures quoted at the end of last month for railway material required by the Magdeburg railway administration. The following were the successful contractors: Carl Delius, of Magdeburg, for 700 tons of bar iron at 140s. per ton. This corresponds to about 126s. per ton at the works in Westphalia. The ruling price at the same time last year was 91s., thus showing an enormous improvement in the market. A. Druckenmüller, of Berlin, obtained the contract for 59 tons of rivet iron at 150s. per ton, which price is low in comparison with that of bar iron. A rolling mill in Upper Silesia obtained the contract for heavy sheets at 142s., whilst the contract for fine sheets was secured by Messrs. Grillo, Funke, & Co., at 156s. per ton. The Cologne railway administration have ordered a batch of railway waggons. Amongst these are some goods waggons with Carpenter brakes, quoted at £382 each, and some smaller waggons with hand brakes, quoted at £295 each, by the Düsseldorf Railway Supply Company. Harkort, of Duisburg, has secured an order for fifty coal waggons, made entirely of iron, at £87 each. The Frankfort railway administration have ordered a parcel of steel rails from the Hörde Company at 125s., and some steel sleepers from the Aix-la-Chapelle Company at 135s. per ton.

TEXTILES.—Satisfactory reports are to hand regarding the worsted and stocking trades of Saxony, where manufacturers have sufficient orders on hand to keep their works going full time, and at fairly remunerative prices. Tricots are in strong request in the south of Germany for export to North and South America, and several works have ordered a considerable number of new looms, In gloves the trade is also reviving. Dr. Lahmann's "reform cotton goods" are beginning to be well appreciated, and a brisk trade is being done in this kind of article.

ELECTRIC LIGHTING.—The experiment recently made in Berlin of joining the underground mains of two central stations has proved completely successful. Hitherto the network belonging to each station has been kept distinct from neighbouring mains, but as such a sub-division entailed greater administrative expenses and a greater outlay for reserve machinery, the Allgemeine Elektricitats Gesellschaft resolved to join their two stations, one in the Markgrafenstrasse and the other in the Mauerstrasse, so that during the day time and late at night only one of these stations need be kept at work. I have during the holidays visited various Continental towns with the object, amongst others, of ascertaining what progress has been made in electric lighting. The following is a short account of my experience: The railway stations at Bonn and Mayence, and a portion of the goods yard in the former, are now lighted electrically, whilst the work of installation at the Frankfort-on-the-Maine central railway station is rapidly progressing. In Darmstadt the railway station buildings and the goods yard have also been electrically lighted; and a central station for the public supply of electricity in this town will be taken in hand as soon as the frost permits of building operations, whilst the installation at the Court Theatre is already finished. The railway station at Carlsruhe is lighted throughout by electricity, and glow lamps are also installed in a covered arcade in the town containing shops. The electric light installation in the Strasburg railway station, which was put up some time ago, continues to give great satisfaction. A project is on foot in Basle for utilising the water power of the new Rhine canal for lighting the town, but the concession will not be given to a private contractor, since the town authorities wish to keep the business in their own hands. In Zürich the railway station and some neighbouring restaurants are electrically lighted. The central electric light station at Lucerne is now supplying about 4000 glow lamps, but further extensions are in progress. As your readers probably know, alternating currents are used in this instance. The machines were made by Messrs. Ganz and Co., of Buda-Pesth, and are installed about four miles from the town, where water power is available. The current is conveyed to Lucerne by overhead conductors, and Zipernowsky transformers are used. A good deal of activity in electric lighting, and especially in utilising water power for this purpose, is now being developed in Switzerland.

VIENNA, 2ND JANUARY, 1888.

THE IRON MARKET.—It has now been officially announced that the syndicate of iron masters has been established up to the end of 1890. The delay to which I alluded last week arose from the difficulty of conciliating the claims of different works in the distribution of the permissible output for each. Bohemian iron works have obtained some concession in the schedule of distribution which will allow them to turn out about 5000 tons more than during the past year, and the Ternitz works are permitted to increase their output by 800 tons. On the other hand, the Witkowitz works sacrifice about 1200 tons, and the rest is divided between other Austrian and Hungarian works. Otherwise no important alterations have been made in the constitution of the previous syndicate, which was formed on the 1st May, 1886, and the main objects of the new syndicate are also identical, viz., to do away with over production, to obtain a uniform classification of the products, and to regulate prices and customs in the trade. The announcement that the syndicate has been definitely established has not had any influence on the condition of the iron market, as at no time was the success of the movement seriously doubted. The market remains exceedingly dull, which is partly due to the holiday season, but mainly to rumours of war. Bohemian engineering shops are an exception to the general depressed condition of the market, and are fairly busy with agricultural machinery, boilers, and apparatus for sugar works. On the whole, the position of the iron and steel trades during the year which has just passed has been better than in the two or three previous years. The demand for rails during 1887 was by 20,000 tons greater than in 1886, and the quantities sold of building iron castings and other finished goods were greater than in the previous year. The same was the case with machinery, boilers, and railway material. There was also, on the whole, a slight improvement in the prices of crude and finished iron, and this was especially noticeable as regards sheets, nails, and wire. The Hungarian Government have definitely decided to discontinue the management of the State iron works from the 1st instant, and these works will therefore be offered for private management. The more important of these works are the following: In Transylvania, Vajda Hunyad, and Gyalar; in Hungary, Gömor, Sohl, Marmaros, and Szolnok-Doboka.

MINING.—In estimating the possible prosperity of the above works when under an energetic and intelligent management, some account should be taken of the mineral resources of the district, and in this connection the following details may perhaps be of interest to your readers. Transylvania and Hungary are exceedingly rich in iron ores. In the former district the largest deposit is that of Gyalar, where the ironstone contains 40 per cent. of iron, and under the present Government administration the cost of mining it amounts to about 2s. 6d. per ton at the mine, and including freight and other charges 3s. 2d. delivered at the furnace of the nearest iron works. The deposit extends over an area of 7 miles by 3 miles, and is of considerable depth, and rough estimates put the quantity which can be extracted by open work at 32 million tons. In Hungary proper there are three principal deposits of ironstone now worked under State management. The ore also contains about 40 per cent. of iron, and in some places considerable quantities of manganese. These deposits are not continuous, but are separated by private mines, the right of way, however, being secured by Government. The ores are magnetite, limonite containing oxides of manganese, and oligonite, and they are specially suited for the production of ferro-manganese. There are other smaller mines also offered for private exploitation, and the total quantity of ores which might be extracted is estimated at 40 million tons. The total value of the mines and iron works which have hitherto been under the management of the Hungarian Government is estimated at about £7,000,000. The Government has stipulated that whatever party may take over these works must agree to develop the industries which were begun under Government administration, amongst which are those of the manufacture of steel in various forms, enamelled iron ware, and cast iron pipes.

THE PETROLEUM INDUSTRY IN GALICIA.—The owners of petroleum wells in Galicia have during the year which has just passed not found this industry a very profitable one. Although the area over which petroleum occurs is very considerable, amounting to about 1500 English square miles, the local yield is small, in many cases not exceeding 1½ barrels per day per bore hole, whilst the price of Galician petroleum has ruled very low, varying from 4s. to 5s. 6d. per ton. Russian oils can be delivered here for 7s. per ton. The cost of sinking bore holes in the eastern portion of Galicia amounts to about 75s. per yard, whilst in the western portion the cost is only 20s. per yard. During the last six years there were sunk 280 bore holes averaging in depth from 200 to 400 yards. There are about 50 boring engines at work, besides a considerable number of hand drills, and quite recently diamond drills have been introduced so as to accelerate the work.

BRUSSELS, 3RD JANUARY, 1888.

THE COAL MARKET.—The situation in the iron trade is affecting the other markets, and coke is very scarce, as well as small coking coal. Some makers propose to charge 12s. per ton for coke, and speak of still higher rates for future delivery. This rise will harm a number of furnaces which have sold their production at low rates. It is evident that under the circumstances blast furnace owners will have to raise the price for pig. The rates for other kinds of coal continue the same as reported in my last letter. Owing to cold weather having set in, there is a better demand for household coal.

THE METAL MARKET.—Although at this time of the year the demand is usually small, rolling mills have difficulty in fulfilling the orders which flow in. Prices of finished iron have risen 4s. per ton, and if this condition of affairs is maintained until spring, a good business year will follow. Engineering works have difficulty in obtaining prices corresponding to the rise in raw materials, the rate for ingot copper being £82 per ton, for tin £164, for zinc £20. 16s. to £20. 12s., and regulus of antimony £50 to £52. There is plenty of work in girders, special sections, and sheets. Pig iron is scarce. The management of the economic railways are going to order a hundred carriages. For the State railways a number of luxurious international cars will be required. There will also be ordered from home makers three hundred trucks and one hundred locomotives. The outlook is therefore very good in this branch of business. Steel works have not much in the way of rails in hand, but further work is in course of negotiation, and orders have been received for metal sleepers, axle boxes, and other railway material. Makers of springs and buffers are busy.

FLAX AND YARN MARKETS.—The Belgian market for home-grown flax exhibits no new features. Generally the amount of business transacted is less than it was a few weeks ago, and prices show a weakening tendency. Probably this state of things is in part attributable to the season. A commonly held opinion is that the demand will strengthen after the middle of this month. At Bruges the market is dull, but flax of good quality finds a ready sale at firm prices. At Courtrai business has shrunk within narrow limits, but there, too, a good demand is reported for the higher qualities. At Ghent there has been more flax on offer this week, and prices are weaker. A considerable amount of buying has taken place in Russian.

Digitized by Google

Linen yarns move heavily in the market, and what little demand there is, is for tow yarns. Cotton yarns are not much sought after, business being delayed on the part of consumers in the hope of easier prices.

Railways, Posts, and Telegraphs.—A report has been issued on the operations of the State railways, posts, and telegraphs during the last official year, from which it appears that three new types of locomotives have been adopted for light traffic, fourteen new carriages have been ordered, and 150 carriages have been altered so as to have a central gangway. At present one hundred carriages for train-tramways are being built. Oil, gas, and electric lighting have been extended. The receipts show a diminution compared with the previous year. The number of accidents has been steadily decreasing since 1880, and only 113 cases of collision or derailment are cited in the present report. There were 3 railway passengers killed, 27 wounded, and 13 received contusions. Among railway servants 56 were killed, 241 wounded, and 56 received contusions.—In the posts and telegraphs section, there has been a falling off in the letter traffic, but the number of telegrams has slightly increased. Three new telephone systems have been established, having as their centres Ostend, La Louvière, and Ieseghem. An increase has taken place in the receipts of the mail steamers between Ostend and Dover.

DÜSSELDORF, 2nd January, 1888.

State and Prospects of the Iron Market.—As there is nothing to record of the iron markets this week but the fact that business has, as usual, been brought practically to a standstill by the Christmas and New Year holidays, I will set out for review the salient features of the situation, and try to forecast the near future of the trade. Not the least suggestive, perhaps, of the events which have marked the course of the year now ended is the unusual heartiness with which the Christmas festivities have been indulged in. Clearly the pinch of adversity is no longer felt. The contrast between 1887 and 1886 in this respect is very striking, The revival dates back to the beginning of last year. Consumption of iron has steadily grown down to the present time, bringing a constantly increasing demand. The improvement was not confined to the home markets. The foreign demand kept pace with the home requirements, and helped materially to swell the total volume of trade. A remarkable feature of the revival has been its persistence. There has been no interruption of its progress. At first, competition being exceedingly keen, prices showed but little tendency to follow the movement in volume. To remedy this, the syndicate system was adopted, and the results arrived at have far exceeded the hopes of the most sanguine. Under this system, a rapid and great advance in prices has taken place, changing the situation for the manufacturers from one of profitless production to one of very remunerative work. The demand has continued unchecked by these enhanced prices, and is now, with a much larger make of pig iron and increased imports of foreign pig, well ahead of production. What the course of the trade will be in the first half of the year on which we have entered it is not hard to predict, for it is already marked out. Blast furnace owners have sold the whole of their make of iron in the first three months, and orders are being rapidly booked for delivery in the second quarter. Makers of finished iron and steel are not dealing speculatively in thus buying far forward, for they, too, have their order books filled for four, five, and, in some instances, six months to come, and business continues to flow in. In these circumstances, with the whole trade controlled by syndicates, it is certain, leaving war only out of account, that the present situation is assured for at least six months to come, and that the second half of the year is likely to show the same features which will distinguish the first. Thus we enter upon 1888 with prospects that justify the tone of confidence now prevailing, and strengthen the hope of a long-to-be-continued prosperity.

The Wages of Iron Workers.—The annual balance sheets of the great iron works' companies, recently issued, show an improvement in the rate of wages paid in the business year 1886-87 relatively to 1885-86. Thus the accounts of the Dortmund "Union" gave an average annual rate of £47. 2s. 3d. per head against £46. 19s. 2d. Again, those of the Bochum "Verein" gave an average of £48. 19s, 10d., against £47. 3s., or leaving out all hands under twenty years of age, £51. 18s. 5d., against £49. 13s. 2d. Those of the Wesphalian "Union" at Hamm give a general average of £41. 8s. 3d., against £39. 14s. 5d.

The Zinc Market.—The demand for zinc steadily increases and prices as steadily tend upward. This market contrasts favourably with that of copper, which is entirely in the hands of speculators. The prevailing activity is due to a larger consumption of the metal, and the advancing rates are fully justified by the state of trade. Prices had reached a very low level, stocks are practically exhausted, and the requirements of consumption are in excess of production. The average price of Silesian spelter fell from £16. 6s. a ton in 1882 to £14. 10s. in 1883, to £14. 0s. 10d. in 1884, and to £13. 10s. in 1885, at which price it remained stationary throughout 1886. From the middle of June to the beginning of December, 1887, the prices increased £3 a ton, and between that date and the end of the month it rose to £18. 6s. The production of Silesian spelter in the above mentioned years amounted to 69,846 tons, 71,466 tons, 77,278 tons, 80,838 tons, and 82,730 tons, respectively.

LILLE, 3rd January, 1888.

Textile Manufactures.—The trade in textile goods continues to make steady progress towards recovery, and the markets are evidently tending towards greater activity. The linen goods trade has become fairly animated. Buyers from the wholesale houses of the Eastern districts have operated largely within the last few days, but manufacturers complain of low prices. At Rouen business in cotton goods increases, but is not yet sufficient to impart a cheerful tone to the markets. At Roubaix the recent advance in combed wool has been partly lost. There is, however, buoyancy in the markets, which will doubtless make itself felt after the holidays. Spinners are asking higher prices for yarns, a good indication of the tendency of business. There is some animation in the business in woollen stuff goods, but the demand is for the moment confined chiefly to novelties. The export trade is wanting in animation. The values of the woven goods exported in the first eleven months of 1887 are as follows, the figures within brackets representing the values for the corresponding period of 1886: Woollen goods, £12,714,480 (£13,726,000); cotton goods, £4,162,600 (£3,952,000); linen and hempen goods, £282,240 (£509,240); jute goods, £115,920 (£73,600); and silk goods, £7,977,960 (£9,514,240).

Flax and Yarn Markets.—The demand for home grown flax is strong, and prices move in favour of sellers. Walloons from Douai and Bergues are much sought after. The activity which I reported last week in Russian "futures" continues unabated. As a consequence prices are hardening. There is a strong current of business in yarns of all classes. For the fine and medium numbers spinners are asking higher prices. Some important sales of Riga tows have been effected this week on foreign account. Jute yarns are still in strong demand at steadily rising prices.

The Iron Market.—The higher rates for iron are now readily paid, and the only matter about which there is dispute is the time of delivery. The merchants, in anticipation of further advances, seek to contract at present rates for delivery in the second quarter of the year, but manufacturers generally refuse to bind themselves beyond the end of March. The market is animated, the demand being brisk for nearly all classes of iron. The Algerian syndicate is now complete, and came into force on the 1st instant.

The Sugar Crop.—The latest estimates of the sugar production of Europe, founded upon the results already arrived at, are as follow: Germany 900,000 tons, France 425,000 tons, Austria-Hungary 420,000 tons, Russia 400,000 tons, Belgium 95,000 tons, and Holland 50,000 tons; total 2,200,000 tons against 2,630,000 tons last year.

WINTERTHUR, 2nd January, 1888.

Railways.—The management of the St. Gothard railway have decided to commence doubling the track shortly. The second track on the section Faido-Airolo is to be in working order by 1890, that on the section Faido-Biasca by 1892, and that on the section Göschenen-Erstfeld by 1896. The estimated cost of doubling the line is £520,000. A one-metre gauge line is projected in the Engelbergerthal to feed the Brünig railway; it will run from Hergiswyl through Stans, Büren, Wolfenschiessen, and Grafenort. The estimated cost of construction is £3,600 per mile.

Arms.—There will be plenty of work for our arms factories this year, as the Landwehr artillery is to be equipped with fifty-six new cannon, at a cost of £14,400. The Vetterli repeating rifle, which up to the present has given excellent results, will also soon have to be changed for a type with a smaller bore, preliminary trials with which have already proved eminently satisfactory. The Budget for this year contains an item of £20,000 for the Gothard fortifications.

The Paris Exhibition.—On the whole there is not much anxiety shown in Switzerland to take part in this Exhibition, and machinery makers and others, who would be put to great expense in being represented, are holding back. Watch makers, on the contrary, who can make a valuable display in a small space, are more disposed to patronise the Exhibition. Lace makers also feel it necessary not to let Saxony have the field to herself. In order to reduce expenses, an effort is being made to get intending exhibitors to act in concert, instead of independently. Switzerland has now decided to take part in the Exhibition officially, and the Commercial Department has appointed Colonel Vögeli-Bodmer as a commissioner.

MADRID, 2nd January, 1888.

Telephony.—The contract to establish a telephone station at Cadiz is offered for public tender under payment to the Government of 10 per cent. of the gross receipts. The system, if limited to the town itself, would be of but little importance; but if Jerez, Port St. Mary, and other small places surrounding Cadiz were included, the business would pay. The Madrid Telephone Company is doing very well; their charge is £12 a year, but a reduction would greatly increase the number of subscribers.

Railways.—A line of railway, owned by a number of Oporto capitalists, has been opened for traffic from Salamanca to the Portuguese frontier. There have been some engineering difficulties to overcome, and though the length of the line is only about fifty miles, twenty tunnels had to be bored. A Bill is being prepared which will give an impulse to the construction of economic railways, a large number of concessions will be made, and probably the line from Calatayud to Teruel, which has been repeatedly offered as a broad gauge line, will now be submitted as a narrow gauge line. It is reported that a syndicate is being formed by M. Anspach, the Belgian financier, to take over all the central lines. English capitalists might do well to turn their attention to railways here, which, if the cost of construction be kept within reasonable limits, should pay from 7 to 9 per cent.

ST. PETERSBURG, 31st December, 1887.

Railways.—A new route has been projected by Mr. Protzenko for the Siberian railway, which differs considerably from other schemes. He proposes to commence the line at Zlataousk, and to pass through the thickly populated districts of Tchelahou and Kourghan, along the southern confines of the Ishimsky district to Omsk. The road next proceeds in a straight line to Tomsk and Krasnoyarsk, crossing the rivers Irtish, Ohi, and Yenisei to Irkutsk, and then to the northern end of Lake Baika, where there are several large iron works. It then turns north-east, crossing the rivers Vitim and East Olekmon, by which it is connected with the Yakutsk gold fields. It would next cross either the Stanovoi or Jablonoi mountains, and run along the river Oura to the Amoor, and past Khabarodka to Vladivostock. As this port is closed for two months each winter, an alternative route, provided the consent of Corea were obtained, would be along the coast of the sea of Japan to port Lazaret, which is open all the year round. The total length of the line would be 3978 miles, the estimated cost being about £40,000,000. Surveys have already been begun for a line between Tomsk and Irkutsk, and the municipality of the former town have granted 270 acres of townland for railway works and stations. Traffic has now been opened on a new line of railway between Valka and Dorpat, in the government of Livonia.

Harbour Works.—The port of Mariopot, on the Sea of Azov, will, when finished, be one of the finest in Russia. The new works were commenced last year, and are to be completed in 1893, the estimated cost being four and a half million roubles. The contract is in the hands of the firm which constructed the St. Petersburg Canal.

NEW YORK, 24th December, 1887.

Cotton.—Statistics have been published in reference to the statement that the yield of cotton per acre tends to decrease with the extension of the area under cotton in the United States. The figures, which deal with the period between 1879 and 1887, show that though there has been some recovery in the last two years, the general tendency has been downwards, and this is attributed partly to the exhaustion of old lands, to the increase in acreage being mainly in poorer tracts, to the tendency to sell the seed for manufacturing purposes instead of using it on the land as formerly, and to the indiscriminate use of artificial fertilisers.

Iron Production.—Estimates of the production of iron during the present year place the quantity at about 6,300,000 tons, an increase of over 10 per cent. as compared with last year, and over 50 per cent. as compared with 1885. It is calculated that about 13,000,000 tons of iron ore have been consumed during the year.

Oil Works.—The Standard Oil Company has bought up the Toledo Oil Company of Ohio, which refines coal oil, for £20,000.

Cable Traction.—The Rapid Transit Cable Company has been incorporated, with a capital of £20,000. Its object is to introduce an improved cable motor gripper and curve devices for drawing heavy rolling stock on elevated and other railways. The new system bears a similarity to that employed on the Brooklyn Bridge.

Automatic Coupler Tests.—A committee was instituted some time ago with a view to bring about the adoption of a uniform draw bar and coupler for freight trains. Tests were made under the superintendence of the committee with four link and pin and seven vertical couplers, but it was decided that further trials should be made. According to the report of the committee, which has just been issued, these trials took place in the yard of the West Shore Railroad at Weehawken. The first service test was made, on October 14th, with five cars equipped with the Janney freight coupler, and five cars equipped with the Dowling automatic coupler. It was found that cars having each type of coupler could readily be coupled together, and that the Dowling and Janney coupled with each other and uncoupled without difficulty on straight and curved tracks. The hook of one coupler, which was coupled to an ordinary draw bar with a link, broke, the fracture showing that the material was not properly applicable to that purpose. The trial of coupling the Dowling and Janney couplers on a curve of 31½° proved that while each coupler would couple with that of its own class, it would not couple readily with the other on the curve. Physical tests were made with four couplers during the second week in October by Captain Michaelis at the Troy Iron and Steel Company's works, and according to the report presented by him to the committee, the results obtained were not satisfactory, since the couplers broke under the tests. The conclusion arrived at by the committee is that none of the couplers presented fulfil the conditions requisite in a coupler before it can be generally adopted, and they recommend that competitors should not prepare for further tests until they have made such modifications as are necessary to fully meet the requirements of the committee.

HARGREAVES' THERMO-MOTOR.

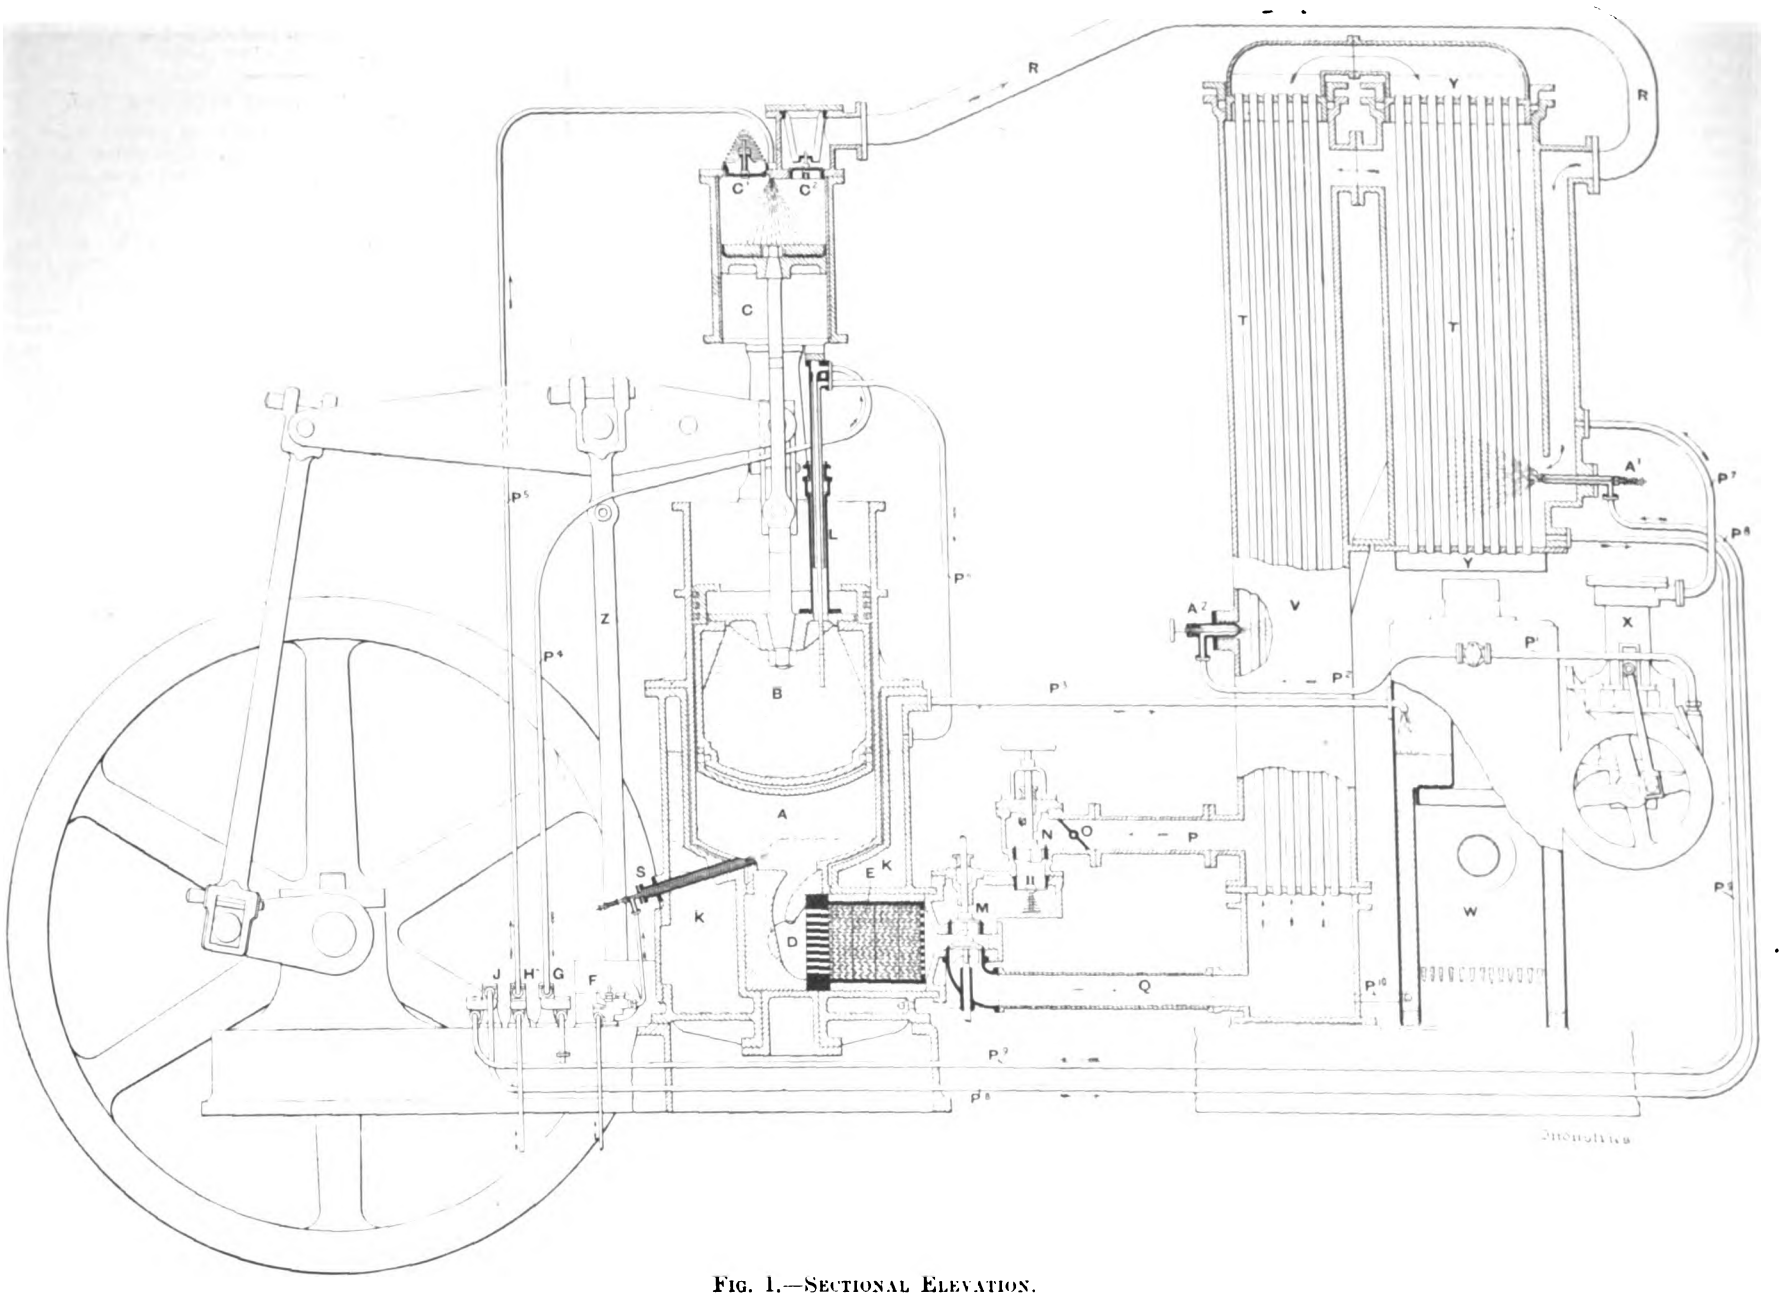

FIG. 1.—SECTIONAL ELEVATION.

HARGREAVES' THERMO-MOTOR.

FROM the researches and investigations of Carnot, Joule, Rankine, Clausius, and Sir William Thompson, the science of thermo-dynamics has not only been brought into existence, but fully matured. We learn from it, that whereas, in the steam engine, on account of the limited range of temperature in the working cylinder, and the rapid conduction of steam during condensation, no combination of cylinders can materially affect its present efficiency; internally fired engines, such as gas and caloric engines—being, as it were, less fettered—can have their already high efficiency increased by simply overcoming mechanical difficulties. To this fact is no doubt due the recent remarkable development of gas and caloric engines. The first caloric, or hot air engine, was invented by Sir George Cayley in 1807, and in 1827 Dr. Robert Stirling, a Scotch minister, took out his first patent for a hot air engine, which was the foundation of many subsequent machines, and by the invention of the regenerator he converted what was practically a scientific toy into an efficient machine.

One of the most ardent workers in this field at the present time is Mr. James Hargreaves, of Widnes, who, with a thorough theoretical knowledge of the subject, has, after many years of patient perseverance, overcome many of the mechanical difficulties, and designed the engine of which the above is an illustration.

The sectional elevation, shown in Fig. 1, is an expanded view of the machine, shown thus to enable the action of the machine to be more clearly understood; the relative position of the different parts, as actually made, is shown in the side elevation (Fig. 4). The principal working parts of the machine are the combustion chamber D, which is of the form shown, lined with fire brick, and having an entrance, with the door screwed down like a manhole lid; the working cylinder A, surrounded by the water casing K; the piston B, with a water lining, and coupled to the end of the working beam by a parallel motion, the beam being supported by two rocking columns Z, as in engines of the "grasshopper" type; the air compressor C, coupled directly to the piston of the working cylinder; the injection pump F, for supplying the fuel—creosote or coal tar—to the combustion chamber; the regenerator E; the receiver and separator V Y; the feed and exhaust valves M.

The action of the machine is as follows: Assuming the engine to be in condition for starting, the sides of the combustion chamber D are red hot, the chamber charged

FIG. 2.

with air, and the spray of creosote, injected by the pump F, is ignited; the expansion of the gases produced by the combustion acts upon the bottom of the piston B, forcing it to the top of the cylinder, and thus, by intermediate mechanism, causing the crank shaft to revolve. By the same stroke a charge of air is forced by the compressor C into the receiver through the pipe R. The cylinder is, of course, single acting, and on the down stroke of the piston B—which falls by its own weight and the momentum of the fly wheel—the exhaust gases are forced through the regenerator E, which absorbs most of their heat; they then pass through the exhaust valve, placed immediately under the feed valve M, along the pipe Q, up through the pipes T fitted into the receiver V, down the pipes T fitted into the saturator Y, and out of the funnel fixed to the bottom of Y.

The charge of air for supplying the combustion chamber is forced by the compressor C through the pipe R, *outside* the tubes T in the chambers V and Y, along the pipe P, through the feed valve M and the regenerator E into the combustion chamber. In its passage from the compressor, it first picks up the residual heat of the exhaust gases in the tubes T, and finally the heat absorbed by the regenerator E, thus entering the combustion chamber in a highly heated state. Having described generally the passage of the air from the compressor to the working cylinder, and back again to the funnel, we will now describe the details. The working cylinder A is fitted into the casting which forms the water casing K, a space being left between the bottom of the cylinder and the casing, which is filled with a non-conducting mixture of asbestos to protect it from the heat of combustion; the bottom of the piston B has a similar protection, and the regenerator has a lining of the same mixture, to prevent any heat from escaping through the casting which holds it. The water in the casing K and in the piston B is supplied by a small pump G, which forces the water through the pipe P_4 into the telescopic pipe L, either into the piston B or through the pipe P_6 into the casing K—the bottom of the casing being connected by the pipe P_{10} with the auxiliary boiler W. The steam generated in the casing K is carried to the boiler W by the pipe P_3, and from the boiler it passes along the pipe P_2, through the valve A_2, into the chamber V, thus giving up its heat to the incoming air, with which it mixes. The vapour gradually condenses at the bottom of the vessel Y, and the water so formed is drawn by the pump J along the suction pipe P_9, and forced through the pipe P_5, back to the chamber Y through the valve A_1, and in the form of spray plays on the tubes T, and absorbing any residual heat. The heat generated by compression in the cylinder C is absorbed

Digitized by Google

by a spray of water from the pump H, the vapour being carried along with the air through the pipe R to the chamber Y, where it is separated, and falling to the bottom is circulated, as just described, by the pump J.

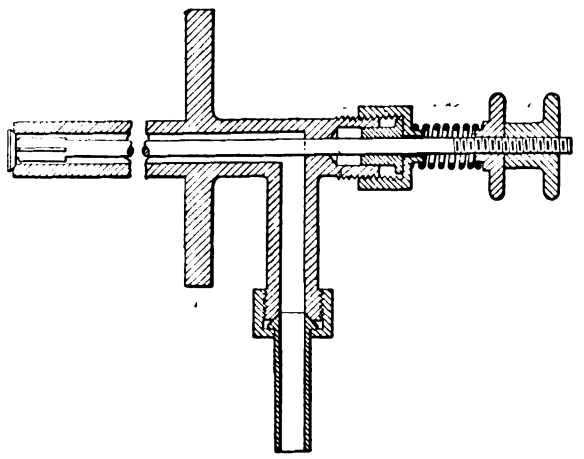

FIG. 3.

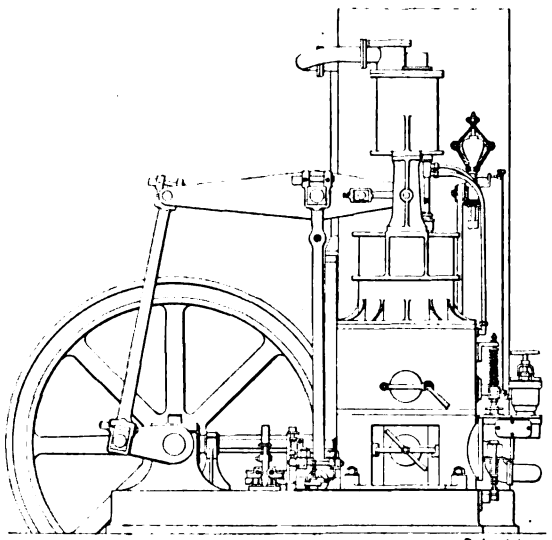

FIG. 4.

X is a small auxiliary air compressor, to obtain the necessary compression to start the engine, and is worked from the boiler W. In future engines this compressor will be superseded by a specially designed injector, which will produce the necessary pressure at a considerable reduction in cost. When once the engine is started, the fire of the auxiliary boiler can, of course, be drawn, as the main engine afterwards makes its own steam. The regenerator E has circular ends of fire clay perforated, the body being filled with fire clay spirals of the shape clearly shown in elevation in Fig. 2. The injector valve for the creosote is shown to a larger scale in Fig. 3; this valve has, however, been since considerably modified and improved. The feed and exhaust valves M are actuated by cams keyed to a counter shaft driven by bevel wheels from the main shaft. The creosote pump F is also worked by a cam on the same shaft, but the pumps G H J are worked by eccentrics. A stop valve N is fixed to the supply pipe P, under which is placed a back pressure valve to retain the pressure in the combustion chamber. The engine is regulated by an ordinary Porter governor actuating the throttle valve O. An engine, as described, has been constructed by Messrs. Adair & Co., engineers, Waterloo Road, Liverpool, and has been running most satisfactorily for several weeks, the results being clearly shown by the indicator diagrams (Figs. 5 and 6). The results obtained by this motor are very remarkable, and are a long way in advance of any previous performance, as only a little over ½lb. of fuel is used per i.h.p. per hour. It may be mentioned that the temperature of the combustion chamber is calculated to be about 2500°F., and that of the exhaust gases does not exceed 180°F.

METALS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—The market continues firm at about £85 per ton for Chili bars. It is said that the speculators in Paris, who act by a syndicate, so as to control the market quite artificially, are now endeavouring to keep the present price of copper steady, so as to unload their stocks, and realise the large profits which at present exist only on paper. They have probably been led to this course by the attention their proceedings have received of late from the Paris press, and the threat of Government interference. It is clear that the metal trade has been seriously hampered by their proceedings, and the best course is evidently to steady prices without forcing them further until they would become impracticable. The present price of manufactured copper, £90 per ton for "strong," is based upon a much lower price than that current for Chili bars, viz., on about £78 per ton for raw copper, as compared with £85 for Chili bars. It is thus a favourable price for the consumer, and should encourage exporters to place orders for early shipment, as the stocks abroad are now very low.

TIN remains firm, being strongly held; but a belief gains ground that the price cannot be maintained much longer at its present high figure. Straits tin may be quoted £167, whilst English tin is from £148 to £150. There was a remarkable note in the *Times'* money article of Tuesday from importers of Straits tin, stating that the cost price was only £78 per ton, equal to London delivery, and that the output was being greatly increased, the Chinese miners working day and night, so that stocks were beginning to accumulate. The present price is very much higher than it ought to be, and there is good prospect of an early reduction on account of increased supplies.

LEAD remains at about last week's prices, £15. 10s. to £16 per ton.

SPELTER continues firm at advancing prices. Spot parcels are scarce, and many of the largest works in Silesia and Belgium have sold their whole production for many months to come, so that forward quotations have advanced greatly. The English smelters are also sold a long way ahead. This metal will be likely to continue dear, as the demand has quite overtaken the production, and the advance has been caused by natural and not by speculative influences.

HOME INDUSTRIES.

MANCHESTER, 5TH JANUARY, 1888.

THE COTTON TRADE.—The New Year has opened with promise of better trade for spinners, and although business has scarcely recovered from the effect of the holidays, there is still sufficient being done to afford some indication of the probable tendency. Many spinners sold freely just before the close of the year and are well under contract, while those who are not in that position are content to wait rather than sell unless they can get some advance on recent prices. Some kinds of yarns are sold a long way forward, and bundles especially are very scarce. During the past few weeks free buying of cotton has taken place, and the stocks in the hands of spinners must be very much increased. On the other hand, the supply of yarn is not any larger than is required by the demand, and consequently spinners are enabled to adhere firmly to their quotations. Owing to the difficulty which manufacturers experience in getting corresponding advances for cloth, they are indisposed to pay higher rates to the spinners, and in the home trade it is somewhat difficult to arrange business. The cloth market is in anything but a good state at present, the difficulty being mainly one of prices, which tend to become lower for several reasons. The large increase in the manufacturing power, to which we have before alluded, is now beginning to have its natural influence, and is rendering the competition for orders keener. On the other hand, the augmented use of yarn so created has made that commodity much dearer, a development which is aided by the increasing price of cotton. Thus, the manufacturer has to pay more for his materials, has a wider circle of competitors to meet, and finds an increasing difficulty in obtaining a corresponding advance of rates from his customers. Fortunately many makers are well sold, and can afford to wait before accepting low offers. It is stated that a new company has been floated at Rochdale to build, equip, and work a weaving shed, which is to contain 1350 looms.

THE SHIP CANAL.—Since we last referred to this enterprise considerable progress has been made. Mr. Walker has brought into operation a large quantity of plant, and work is now going on at four points. A novelty in the way of a land dredger, which is made by a German firm, is about to be brought into operation, and is expected to give good results. The quotations of both the ordinary and preference shares have advanced, and after the payment of the next call on the former, which is due on the 16th inst., are likely to become still higher. Since the acquisition of the Bridgewater Navigation Company's canals by the Ship Canal Company, the traffic on them has largely increased, and this route is now becoming a favourite one with shippers.

THE IRON TRADE.—There is an unmistakeable movement in this trade towards higher prices. Whether the advance in pig iron is speculative or not, it has been productive of some free buying, and all round the tone is very firm. Hematites especially are being sold at better prices, and appear likely to advance further. The movement has extended to finished iron, which is now very firmly quoted at a basis of £5 per ton for common bars; but sellers are very indisposed to do much even at that price. In the minor branches of this industry there is a fair trade doing, hoops, for instance, selling freely.

NEW STOP VALVE.—A stop valve is about to be put on the market here, a distinguishing feature of which is that it is seatless. The valve consists of a hollow spindle with its lower end blank, but drilled round its circumference with such a number of holes that their combined area is rather in excess of that of the bore of the spindle. The holes referred to are, when the valve is shut, raised into asbestos packing suitably placed, and when the valve is open are pushed into a steam space. In this way the steam is admitted into a steam chamber, to which the exit pipe is affixed. The amount of steam passed can be regulated by the number of holes uncovered, and the valve has the advantage that leakage can at all times be prevented.

LONDON, 5TH JANUARY, 1888.

THE MONEY MARKET.—After a week of some little stir the money market has become very easy again. The first week of the year always throws a deal of loanable capital on the market, and in view of this there were speculations in the early days of the week as to the likelihood of the Bank directors reducing their rate of discount in keeping with the general tone. Gold still continues to be in demand for Berlin, a fact which is adverse to a reduction; but, on the other hand, considerable sums have just been placed in the Bank, and more is in sight. Another broken week has made the stock markets of less interest, and the ruling tendencies are much as they have been for some time back. Copper still keeps up, and several new mining properties will shortly be brought into the market upon the strength of the present boom. Several hopeful home industrial investments may also be looked for as soon as the holiday influence has passed away. The striking feature of the past month, and indeed of the past year, was the demand for substantial home securities in the form of railway debenture and preference stocks. The number of investments which are absolutely safe does not increase in proportion to the wants of the investing public, hence the enhanced prices of such stocks, which are now almost prohibitive.

COMPANIES.—There were registered during the month of December 203 companies, with an aggregate capital of £21,100,000. Since our last report, the following new companies have been registered: New Minerva Mining Company, Limited, with a capital of £30,000; the Llwydarth Iron, Steel, and Tin Plate Company, Limited, with a capital of £75,000; The Clamond (Continental) Incandescent Gas Light Company, Limited, with a capital of £200,000; the Lawrence Automatic Gas Company, Limited, with a capital of £310,000; and Lockwood's Patent Horse Feeder Company, Limited, with a capital of £3000.

COPPER.—According to Messrs. H. R. Merton & Co.'s report, the stocks of copper in England and France on the 31st December amounted to 34,451 tons, as compared with 54,890 tons, 46,116 tons, and 37,770 tons at the same date in 1886, 1885, and 1884 respectively. Adding the copper advised from Chili and Australia, the amounts are 42,301 tons on 31st December, 1887, 63,290 tons in 1886, 58,170 tons in 1885, and 49,543 tons in 1884. The price per ton for Chili bars was £85, £38. 10s., £41, and £47. 5s. at these dates respectively.

SHIPPING.—With reference to the great increase in ship building which is now taking place, Messrs. Angier Brothers report that freights during the past year were poor and unprofitable for the first six months, followed by a solid progressive improvement during the second half of the year, at least as far as regards the shorter trades. In the long trades there is less encouragement, the improvement being as yet but little felt. They are of opinion that one important fact has been demonstrated, viz., that the present supply of tonnage is not too great for the demand, and that any increase in the general trade of the world would at once lift freights; but this favourable position is likely to be spoiled by the too eager haste of owners to increase their fleets. Second hand tonnage has been largely dealt in during the year, and after touching the lowest price on record has now risen considerably, the number on offer being small.

COAL.—The imports of coal into London during the month of December amounted to 1,211,140 tons, and the quantity conveyed beyond the limits of the coal duty districts to 276,338 tons, as compared with 1,100,856 tons and 272,085 tons in December, 1886. The total imports last year amounted to 12,054,048 tons, as compared with 11,800,507 tons in 1886; and the total exports to 2,997,246 tons, as compared with 2,984,628 tons in 1886. The total net increase in consumption is thus nearly a quarter of a million tons.

SUGAR.—The price of sugar is advancing. Though stocks in the United Kingdom show an increase, it is expected that the visible supplies during the year will decrease, in view of the deficiency in the production of beet and of greater consumption.

THE DRAUGHTSMAN'S PROVIDENT SOCIETY.—This society is to be formally established on the 9th inst. Membership is open to draughtsmen who are in the employ of architects, engineers, or surveyors. Besides the usual death insurance and sick pay allowances, there is also a provision made for advancing loans to members who are in distress. By contributing one shilling a quarter, a member is entitled to borrow a sum not exceeding £10 for a period of six months.

PATENTS.—The applications for patents during 1887 were higher than in any preceding year, the number amounting to 18,029, as against 17,162 in 1886, 16,101 in 1885, and 17,110 in 1884, the first year after the passing of the Act reducing the preliminary fees.

RAILWAYS.—The gross receipts of the twenty-two principal railways in the United Kingdom for the week ending 25th December amounted to £1,258,734 on 15,502½ miles, as compared with £1,155,311 in the corresponding period of 1886, when the mileage was 15,394¾ miles. An increase is thus shown in the mileage of 107¾ miles or 0·6 per cent., and in the receipts of 8·9 per cent.

THE NEW RIFLE.—It is announced that the Small Arms Committee have decided on the new magazine rifle for the infantry, and that one of the new weapons is now finished. It has a bore of rather over 0·3, and is rifled on the Metford principle. The magazine can be detached, and the rifle used as a single shot weapon.

GLASGOW, 5TH JANUARY, 1888.

PROSPECTS FOR THE NEW YEAR.—There can be no doubt that trade this winter has been brisker in Glasgow than for some years past. Ship builders and engineers have fairly well filled order books, and some are even withdrawing estimates, the acceptance of which had been delayed. The briskness in these departments and the considerable gains in iron and ore on the Stock Exchange have infused in commercial circles a feeling of liveliness to which the city has been a stranger for some time. In Greenock, also, the simultaneous rise in sugar and in freights has enabled some houses, who had lost heavily in the bad years, to recoup their losses, in some cases to a large extent. Retail trade has felt the improvement also, and the numbers of unemployed, as compared with those of previous years, would appear to be very much reduced, though on this point the absence of accurate statistics renders it hazardous to draw conclusions. In the flour trade there has been considerable briskness for some months, and the close of the year found stocks unusually low, while imports have been exceptionally heavy. Freights for steamships have been advancing during the last three or four months; but sailing freights have not yet manifested any material improvement. The price of iron touched an extremely low point on November 3rd, when it was quoted at 38s. 5½d.; but the last weeks of the year showed a great rebound, and though some of the advantages have, as usual, been lost, there seems reason to believe that for the present a firm advance has been made.

SHIPBUILDING.—An order has been placed with Messrs. Denny Brothers, Dumbarton, by the Compania Trans-Atlantica of Spain for a steel screw steamship of 5000 tons gross for Atlantic service. Messrs. A. Macmillan and Son, Dumbarton, have booked an order for a screw steamer for a French company. The Preston Town Council have ordered from Messrs. Fleming & Ferguson, Paisley, a dredger capable of dredging 800 tons per hour from a depth of 35ft.

PROPOSED ELEVATED FERRY STEAMERS.—A proposal has been made to construct some elevated ferry steamers for the cross river traffic. At present the traffic is conducted by small steamers, two plying at each ferry. The construction of more commodious vessels to meet the very great traffic is only a question of time. The matter has been remitted to the engineers to examine and report.

CLYDE TRUST.—The quarterly report of the engineer to the Clyde Trust, just issued, shows that the quantity of material dredged from the bed of the Clyde by the dredgers of the Trust, and deposited in Loch Long, is rapidly increasing. The total quantity dredged during the quarter was 354,144 cubic yards, and the quantity deposited in Loch Long alone was 331,640 yards. The new works at Cessnock Dock are being carried on steadily. The west wall of the entrance to the dock is now ready for the granite cope, and the ferry stair in the wall is completed. The Winne cylinders of the east wall of the entrance are being sunk. These Winne cylinders are sunk to a depth of 55ft. below the level of the cope. The new cattle loading bank at Shieldhall, Govan, has been finished during the quarter.

LARGE CORLISS ENGINE.—There is now being shipped at Glasgow, per "Clan Cameron," a very large Corliss engine for a cotton mill in Bombay. The low pressure cylinder is 70in. in diameter, and weighs 27½ tons; the high pressure cylinder is 40in. in diameter, and each has a stroke of 72in. The fly wheel, which is 30ft. in diameter, weighs 110 tons. It is 8ft. 6in. in width, and is grooved for 38 ropes. The crank shaft is made of Whitworth's fluid compressed steel, and is 25in. in diameter. The engine will work up to 2500 h.p. The number of revolutions per minute will be sixty, and the working pressure 100lb. per square inch. The engine has been constructed by Messrs. Douglas & Grant, Kirkcaldy.

LLOYD'S REGISTER AND BASIC STEEL.—The Committee of Lloyd's Register have just issued circulars stating that they now sanction the use of basic steel of ⅝in. in thickness and under, for shipbuilding and boiler making purposes carried out under their supervision, provided that the works supplying such material first satisfy them that they are producing it in accordance with their tests, and of uniform quality. The Glasgow Iron Company, of Wishaw, near Glasgow, are now supplying steel under these conditions.

LIVERPOOL, 4TH JANUARY, 1888.

(From our own Correspondents.)

OPENING OF THE WEST WIRRAL RAILWAY EXTENSION.—An official inspection of the extension of the Mersey Railway to Birkenhead Park, Wallasey, and Hoylake was made last Wednesday by Major-General Hutchinson, who, after a very careful examination, expressed the utmost satisfaction, and unhesitatingly gave his consent for the opening of the lines for passenger traffic on January 2nd. The lines were accordingly opened on that date, but without any ceremony beyond the conveyance of the leading officials along the whole length of the extensions. It is expected that the extensions to West Kirby and to New Brighton will be ready for traffic at Easter. One portion of the railway between the Mersey Tunnel and Birkenhead Park has been constructed under very great difficulties on account of the many quicksands encountered. The company have had to pay heavy compensation to the property owners in Beckwith-street for damage done to the buildings in consequence of the subsidence of the ground. Sir James Brunlees and Sir Douglas Fox were the engineers for the work, Messrs. J. Waddell & Son, of Edinburgh, being the contractors for the Birkenhead Park Extension, and Messrs. Meakin & Dean, of Birkenhead, for the Wirral Railway works.

PRESCOT WATCH MAKING INDUSTRY.—For many years this industry has been in a most depressed state, and a movement has now been set on foot by the Vicar, with the support of the Earl of Derby and other influential men, to build a factory for the manufacturing of watches by machinery to compete with the large American firms. The capital of the company is to be £100,000, in £1 shares. The movement has the entire sympathy of all who know the present suffering of the villagers.

THE LIVERPOOL WATER SUPPLY.—A report embodying several important alterations in the charges for water supplied outside the city has been prepared for the Water Committee and submitted to the Council. The recommendations are as follows: (1) The water supplied by meter outside of the city to be charged 50 per cent. more than that for the supply within; (2) the charge for water supplied by meter to supplement supplies from private wells or canals to be increased; (3) to discontinue the inspection of private hydrants, and to make an annual

Digitized by Google

charge for connecting the same to the mains. The estimated annual increase in the receipts by the adoption of the above recommendation is £3,588.

SHEFFIELD, 4TH JANUARY, 1888.

A RETROSPECT.—One of the most significant evidences of improving trade is the increasing business with the United States. The bulk of trade done by Sheffield in 1886 with America, chiefly in steel and cutlery, was £701,545, whereas, in 1887, the total exports amounted to £1,063,356. In December alone steel to the amount of £27,170 was exported to the United States, and this was a considerable increase on the exports of the two previous months. Other branches of local trade show a decided improvement, and there is everywhere proof of reviving markets, less difficulty in obtaining orders, and more work for skilled artisans.

IRON AND STEEL.—Prices are still firm, and Bessemer billets are selling at higher quotations than those given in this report last week. Makers are sanguine, in fact, that there will be a considerable rise in price before the first quarter of 1888 closes. As an indication of growing business, it may be stated that several Sheffield houses, doing largely in the steel trade, were obliged to curtail the Christmas holidays owing to the pressure of orders. All descriptions of railway material are in steady demand at higher prices, and shipbuilding material is selling well. Corrugated flues, for marine boiler furnaces, are becoming a profitable specialty; and a very large trade is being done in crucible steel castings. There is undoubtedly a reviving shipping trade. Heavy marine castings are more extensively on order; and Messrs. William Jessop and Sons, who have been actively engaged for some months on engine bed plates, rudders, rams, and so on, have their books satisfactorily filled with new orders. There is on every side the admission that competition was never keener; but best quality material is telling in the commercial struggle, and Sheffield firms, now thoroughly roused, are putting down the newest plant, and straining every nerve, to uphold their reputation for good work, and at prices that would, ten years ago, have been considered preposterous. Railway springs are obtainable at £9 per ton; tyres £6, or a little over; axles from £6. 5s. to £6. 10s. per ton. In heavy machinery and other engineering work there is more activity, and employment is easier to get both at the rolling mills and foundries. Indeed, the heavy branches of Sheffield trade have not had a brighter prospect for the past ten years than at the present time. Messrs. John Brown & Co., Limited, have one or two orders on their books, but are waiting for specifications; and Messrs. Charles Cammell & Co. have also a few orders for steel faced plates. Messrs. John Brown & Co., Messrs. Charles Cammell & Co., Messrs. Firth & Sons, and Messrs. Vickers and Co., have now completed and put down enormous plant for the production of heavy ordnance. It is anticipated that the Government, during the next few days, will send very extensive orders to Sheffield.

CUTLERY, &C.—In cutlery, edge tools, silver and electroplate, and skates particularly, the demand is extensive, and orders are coming in daily.

THE MANUFACTURE OF STEEL WHEELS.—Messrs. Hansell & Co., of this town, have arranged to undertake the sole manufacture of the "National" interchangeable steel tramway wheels and axles. The tyre is rolled from cast steel, and the centre is cast in one piece of mild Swedish crucible steel. Each spoke is partly divided towards its end by an oval-shaped opening, and steel bolts pass through holes formed in the sides of these openings in a direction at right angles to the axle, and having a broad spring washer threaded on between the sides. The centre is then placed inside the tyre, and each spoke opening is gradually tightened up, causing each spoke to expand slightly.

NORTH STAFFORDSHIRE, 4TH JANUARY, 1888.

THE IRON TRADE.—Last week a general holiday prevailed throughout the district; and most of the mills and forges only started work again on Monday, orders not being plentiful enough to warrant makers curtailing the usual holiday. The product of the blast furnaces has mostly been put into stock, for which some firms, whose stocks have been decreasing, are not unthankful, in anticipation of an improvement in demand and in prices after quarter day. Consumers are fully bought for the next two and three months at late low rates; and it remains to be seen whether prices will hold out until they are again in the market. Finished iron must see an advance before producers can afford to pay more for the crude metal.

THE COAL TRADE.—The seasonable weather of the last two or three weeks has put the resources of local collieries to the severest test, and where men could be got to work, the pits have been kept going uninterruptedly, even during Christmas week. The holiday in the pottery trade curtailed the demand for that class of fuel, and deliveries of forge coal also fell off. Prices of all coals are low for the time of year, and afford little, if any, margin for profit.

ENGINEERING.—There has not been much work for local founders of late, and prices of all descriptions of castings are unremunerative. The wish is repeatedly expressed that foundry pig iron would go up to 60s. per ton, as under such a condition engineers could do satisfactory work.

COLLIERY EXPLOSION.—Early on Monday morning an explosion of gas occurred at No. 2 pit of the Diglake Colliery, Audley, belonging to the Audley Coal and Iron Company. A fire had broken out in a gob, and although every precaution had been taken to put it out by building stoppings, it got to some gas, and an explosion resulted. Fortunately, owing to the precautionary measures taken, no loss of life occurred. It was afterwards found necessary to fill up No. 2 shaft bottom.

BARROW-IN-FURNESS, 4TH JANUARY, 1888.

SHIPBUILDING AND ENGINEERING.—In connection with the business of shipbuilding and engineering which is being taken over from the Barrow Shipbuilding Company by a new company, of which Mr. Bryce-Douglas is the managing director, it is worthy of remark that one of the features of the new concern is to be a gun factory, which will be under the guidance of Mr. Nordenfelt.

IRON AND STEEL.—The Christmas holidays have attracted attention from business, but it is noticeable that in the iron and steel trades makers have been very well employed, and have been also in receipt of numerous inquiries both for prompt and forward delivery. A firm tone prevails in the market, and there are indications of a brisk trade. Prices are steady at 47s. for mixed numbers of Bessemer iron net at maker's works or f.o.b., and 46s. 3d. to 46s. 6d. forge and foundry samples. Stocks have been somewhat reduced. Steel makers are busy all round, and steel rails and plates are in exceptional demand, the former at £4. 2s. 6d. for heavy sections, and £4. 7s. 6d. for lighter sorts; and the latter at £7. 5s. per ton net f.o.b. Iron ore is exceptionally firm and brisk, and prices range from 9s. 6d. to 13s. 6d., according to quality net at mines.

MIDDLESBROUGH, 4TH JANUARY, 1888.

PIG IRON.—The holidays are hardly over yet, so the pig iron market may be said to be nominal. The tone is firm, however, and prices are unchanged, No. 3 G.M.B running from 33s. to 33s. 3d. per ton for prompt delivery. Warrants are 33s. 6d. per ton cash for Connal's No. 3 G.M.B., and 45s. to 45s. 6d. for Connal's hematite mixed numbers. There has been an increase during the month of December in Connal's store of 12,969 tons. On the 31st December the stock stood at 340,133 tons.

SHIPMENTS OF PIG IRON.—The shipments of pig iron for the month of December amounted to 66,173 tons, as compared with 64,488 tons in November, and 63,777 tons in the month of December, 1886. The shipments for the entire year of 1887 amounted to 814,294 tons, as compared with 783,555 tons in the year 1886. Of the 814,294 tons 444,951 tons went coastwise, and 369,343 tons foreign. Rather more has been shipped to Belgium and Germany, and slightly less to Holland in 1887 than 1886. America has taken 54,080 tons, as against 19,083 tons. Upon the whole the shipments for the past year may be looked upon as very fair, and full of hope for the year now begun.

MANUFACTURED IRON AND STEEL.—The works are still busy, except for the usual lull during the holidays. At the Eston Steel Works there has been a partial stoppage in one department in consequence of the alleged forgery of Lloyds' stamp upon a steel angle iron; but the firm are confident of a satisfactory explanation of the difference between them and Lloyd's inspector being given by the gentleman appointed to arbitrate, and this is asserted after the examination has been passed. The shipments of manufactured steel have increased during the month of December by 5428 tons over those of December in the previous year. In the shipments of manufactured iron and steel India figures largely, having taken 13,224 tons more this December than the previous one.

SUNDERLAND, 4TH JANUARY, 1888.

SHIPBUILDING.—All the shipbuilding firms on the Wear are commencing the year with better prospects than in any of the three previous years. The most recently reported orders are for two steel steamers to be built by the Strand Shipping and Shipbuilding Company, Limited.

MARINE ENGINEERING.—The large marine engineering concerns are now in every case actively employed, and in each the machinery will be worked night and day after the holidays. Ironfounders are also consequently obtaining increased employment.

SHIPPING.—The trade of the port during the last month of the old year has been well maintained, 338,778 tons of coals being shipped, as against 308,751 tons in December, 1886, an increase of 30,027 tons. Shipments of coke and patent fuel were also larger, 5873 tons of the former and 4760 tons of the latter being shipped last month, as compared with 1610 tons and 980 tons in December, 1886. A similar increase is to be noted in the shipment of bottles. Freights continue to be somewhat easier, and it is feared that when the vessels recently ordered are launched, the slight improvement in shipping investments may disappear. More especially is this true of trades in which vessels of 3000 tons and upwards are available, as the great bulk of the cargo carrying steamers now building are of large carrying capacity. In the meantime the outlook is more cheerful, as it is anticipated that there will be a brisk demand for tonnage in the freight market as soon as business gets into its ordinary groove after the holidays.

NEWCASTLE, 4TH JANUARY, 1888.

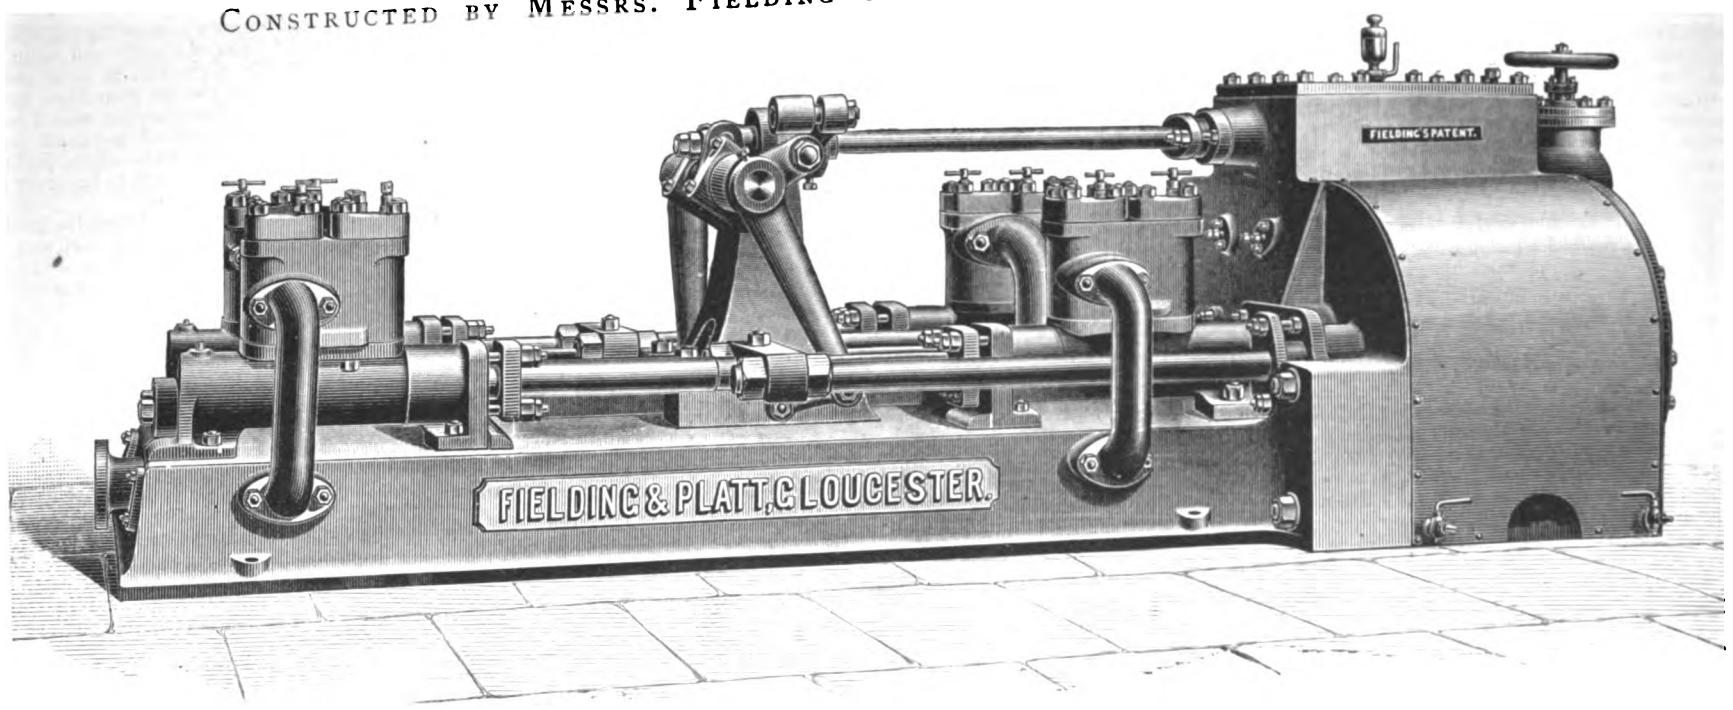
IRON.—The leading iron manufacturers in the district have taken the opportunity, afforded by the observance of the New Year holidays, to effect a thorough repair of furnaces, &c. The inadequacy of the steel supply for ship building purposes has caused a larger inquiry to arise for angle bars &c., manufactured from the older material; and there is little reason to doubt that the works will be kept more constantly employed during the present year than they have been since 1884. The establishments which are specially devoted to the manufacture of merchant iron are generally so well supplied with forward orders, that no prolonged periods of stoppage are expected to occur for at least the first six months of the year.

STEEL.—The newly erected steel works belonging to the Consett Iron and Steel Company have not yet been put in operation, chiefly on account of the unfavourable weather. At the Jarrow Steel Works the pressure of orders is far beyond the existing capabilities of production, but the proprietors are actively carrying out measures to meet the greatly increased demand for such specialties as steel plates, angles, &c. The Redheugh Iron and Steel Sheet Manufactory has been kept going during the whole of the holiday period, the unprecedentedly heavy strain upon the resources of the establishment rendering this course absolutely necessary. The proprietors have recently made some large contracts with London tank makers for the supply of steel and iron sheets over the first half of the year. The prices obtained under these contracts are, as compared with the prices of two months ago, 20s. per ton higher on steel sheets, and from 10s. to 15s. per ton on iron sheets. Those establishments where steel castings are produced are also in full activity, and in some instances arrangements for increasing the output are in progress, or are contemplated.

THE COAL TRADE.—Though the shipments of coal from the Tyne for the week ending December 31st show a large decrease as compared with the shipments in the concluding week of 1886, the year opens with greatly improved prospects for the industry, as the demand for all descriptions of coal produced in the district has been greatly stimulated lately, and many important contracts for forward supply have been secured, thus insuring steady work for months to come at several colleries. The demand for coke, both for home use and exportation, has also largely increased, and the shipments of this commodity have been more than doubled lately, as compared with those of a year ago.

PETROLEUM OIL.—The tank steamer "Petrolea" arrived in the Tyne yesterday, from Libau, with 280,000 gallons refined Russian petroleum. This cargo is from Messrs. Nobel's refineries, Baku, the "region of eternal fire." The Droojba Fountain sends up a column of oil 200 to 300 feet high 18in. in diameter, and forces the oil out of the earth at the rate of 2,400,000 gallons every 24 hours, being nearly equal to the output of all the 20,000 wells in the oil fields of the United States.

DUNDEE, 4TH JANUARY, 1888.



FLAX AND JUTE TRADES.—Owing to the holidays there has been little doing in the local market during the past fortnight. The year opens hopefully, however, and the prospects are better than they usually are at this season. It is calculated that the import of jute during the past year has been 173,346 tons. The trade employed 79 vessels of an aggregate tonnage of 137,000. There has not been so extensive an importation since 1883, when 114 vessels of 162,210 aggregate tonnage arrived. The increasing employment of steamers has been a feature of the trade during the year. At present there are some twenty jute laden sailing vessels bound for Dundee from India. Manufacturers are more and more learning the expediency of cultivating specialties instead of relying on ordinary coarse goods. Carpets, rugs, and checks are now quite common articles of manufacture. The market generally has been favourable to a productive output during the twelve months. The limitation of production at Calcutta has enabled makers to dispose of the stocks that hung on their hands, and business now seems in a healthy condition. In the linen trade signs of of improvement are noticeable in the finer branches, but the market for coarser goods has not been buoyant. Local spinners have felt the competition of French and Belgium yarns. There appears for the moment an increased disposition to invest money in local undertakings. Several important works are likely to be begun this year. Among them are the circular district railway, the Dundee and Highland district line, new water works, and a marine embankment. One of the railway companies is making preparations for building an extensive new station. The value of new property erected within the borough last year was over £100,000.

TIMBER TRADE.—Considerable activity has prevailed in this trade during the year. Eighty-one cargoes arrived, and the number of loads imported was 47,896. In this, as in other trades, the importation is being taken up by steamers. The classes of timber imported were: Yellow pine, 3351 loads; pitch pine, 2885 loads; firewood, 1073 loads; spars, 1232 loads; lathwood, 1473 loads; birch, 218 loads; elm, 152 loads; ash, 88 loads; poplar, 62 loads; and oak, 42 loads. Most of the wood comes from Scandinavian ports, but Cronstadt sent more than any other single place of export, 7181 loads; whilst Quebec sent 4056 loads.

DUPLEX PUMPING ENGINE.

Constructed by Messrs. Fielding & Platt, Engineers, Gloucester.

COLLIERY WARNINGS.

Those who are in the habit of accepting without question statements made with some appearance of authority, are likely to become confused in their opinions if they give heed to all that is written concerning the causes of accidents in mines. The Government Inspectors of mines ascribe, in their last annual report, the gradually diminishing proportion of deaths by accident solely to the system which they administer. The error of this partial view we recently felt ourselves compelled to expose. More extended knowledge, discoveries in science, improved mechanical appliances, and better education count for something in this matter. Now a fresh claimant to the sole honour and rewards of lessening the dangers that beset the occupation of a collier has appeared. For some years past the Press Association has monopolised the services of a prophet whose particular function it is to discern coming events in the domain of coal mining. At least he is expected to foretell the issue of fire damp in increased quantity. The method of procedure is this: The seer having observed from the daily report of the Meteorological Office that the barometer is likely, in the course of the next twenty-four hours, to fall rapidly, writes a paragraph of warning to colliery managers, which the Press Association forthwith sends to the daily newspapers published in the districts affected. The Association has just issued a report in which it claims to have brought about by this means the notable reduction in the number of deaths by explosion per one thousand hands employed which appears in the statistics of the last ten years as compared with the preceding decade; and *The Times* newspaper lends the weight of its authority in support of the contention. We must once more protest against an assumption of this sweeping character. If that of the Government Inspectors was groundless, this is absurd. It is well known that colliery managers give no heed to these warnings, which the Royal Commission on Accidents in Mines condemned as rather pernicious than useful. All such warnings must come too late. The indications of the barometer at the mine demand the prompt and careful attention of the manager, affording as they do trustworthy evidence of the movements of gas. But their whole value lies in the possibility of their being promptly acted upon. To take the warning from the newspaper of the next day is to lock the stable door after the steed has been stolen. So far, therefore, from having alone brought about the improved state of things, it may reasonably be doubted whether this system of colliery warnings has contributed anything to that result. The mischief of making these groundless claims lies, first, in diverting attention from the true causes at work, and, next, in bringing discredit upon a system in itself good and capable, when properly applied, of serving a useful purpose. Whatever is done in weather warnings for colliery managers must be the work of the Meteorological Office, and the warning must be conveyed by telegraph direct to the mines.

AN IMPROVED RATCHET BRACE.

The accompanying illustrations are taken from the *American Machinist*, and show some new forms of ratchet braces, as manufactured by the Lowell Wrench Company, Worcester, Massachusetts. Figs. 1, 3, and 4 represent the tool in different forms. Fig. 1 shows a square ratchet wrench, while Fig. 3 illustrates the same tool changed into a ratchet brace. In Fig. 2 the cap is removed, showing the internal construction. There are two pawls, the lower one of which is engaged with the ratchet, while the other pawl is pressed back into a recess in the casing head

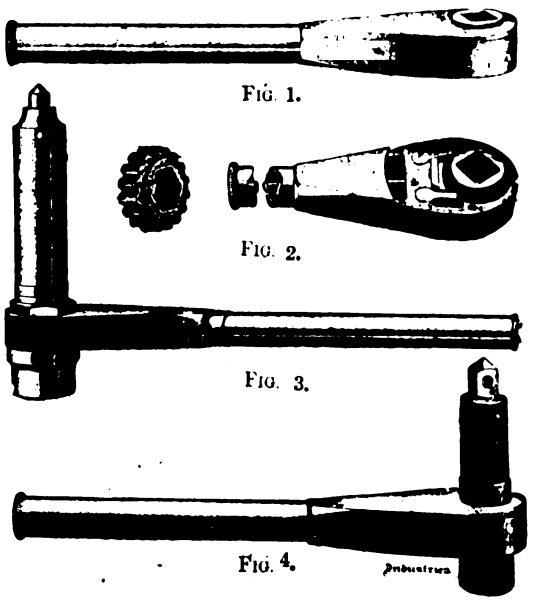

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

by a narrow metal bar capable of sliding to and fro in a transverse groove. This sliding bar is provided with a vertical slot, in which a crank pin slides. This pin is connected to one end of a rod passing through the centre of the handle, while the other end carries a milled button. The pawls are pressed into gear by spiral springs. By turning the milled button, and thereby moving the crank pin either to an extreme left or right position, the sliding bar throws the corresponding pawl out of gear, while the spring pushes the other one into gear. The length of the vertical slot in the sliding bar is so adjusted as to allow the crank pin to go slightly beyond the centre, in which position the pressure of the pawl spring locks the crank. The wrench wheel, one of which is shown at the left of Fig. 2, is made in various shapes and sizes within the limit of the wrench, and can easily be changed by removing the cap. In the same manner the wrench wheel may be removed, and the drill socket substituted, thereby making a complete ratchet brace, as shown in Fig. 3. The possibility of causing a change from right to left hand motion from the end of the handle gives the invention an additional advantage, apart from making the tool look neat and handy. It is sometimes desirable to produce certain motions in places where the hand of the operator could not reach the head of the wrench. This new design allows the reciprocating motion of the handle to be changed to either right or left hand rotation without displacing the wrench. Fig. 4 shows the same principle applied to a tool solely intended for use as a ratchet brace. The comparatively small size of the ratchet wheel and its casing renders this tool extremely useful in places where but a limited space is available for working.

DUPLEX PUMPING ENGINE.

The above illustration shows a new form of duplex engine and pump now working in a satisfactory manner at the Atlas Iron Works of Messrs. Fielding & Platt, engineers, Gloucester. It supplies an accumulator loaded to 1500lb. per square inch. By means of an automatic arrangement the pump is stopped as soon as the accumulator reaches the top, and started again when it begins to descend. There are no chains and balance weights, the only connection between the pump and accumulator being a small delivery pipe. This duplex pumping engine is the patent of Mr. Fielding, and it is manufactured solely by Messrs. Fielding & Platt. We may mention that two sets of compound engines have been working for a considerable period at the shipbuilding yards of Messrs. J. L. Thompson & Sons, Sunderland, and at the works of Messrs. John Readhead & Sons, South Shields. The engines supplied to Messrs. Thompson & Sons have 12in. high pressure and 20in. low pressure cylinders, 12in. stroke, and are pumping water against a pressure of 1500lb., for working Tweddell's hydraulic riveters and winches. It is claimed for this duplex pumping engine, that it is the only non-rotative pumping engine which has positive valve gear. Silence and smoothness of working have thus been completely secured, and efficiency, reliability, and durability have been maintained. The change of design embodied in this valve gear is important, when it is recalled that duplex pumping engines have hitherto mostly consisted of two entirely distinct and complete engines placed side by side, the slide valve of each being operated by the cross head of the other. The distinctive feature, then, of the Fielding engine is that instead of each cylinder being fitted with its own slide valve a single valve serves both cylinders, an arrangement which causes a reduction in the number of parts subject to wear and requiring attention. As each pump plunger begins its stroke the other comes to rest, and in this way the flow of water in the suction and delivery pipes is steadily maintained with little or no pulsation, whilst a pause is made by each plunger at the end of the stroke, enabling the chamber to be completely charged—the valves closing by their own weight alone, thereby insuring small and even wear.

Industries:

FRIDAY, 6TH JANUARY, 1888.

A RETROSPECT AND A FORECAST.

IT is an excellent practice, and one that can never fail to be profitable in its ultimate results, to take stock at the commencement of a new year, with a view to ascertaining how far we have progressed or receded in the period that has just passed. A retrospect for the year 1887 is necessarily one of mixed colours, but it is not quite so unrelieved in its sombre tints as that which we had to draw at this time last year. The outlook is decidedly brighter. The amount of business actually done during the year has been greater almost than during the previous year in almost every department of industry; but whilst the volume of trade has thus been enlarged the range of prices, with all the improvement of demand, and increase of confidence, continues to be almost unprecedentedly low.

Owing to the interdependence between agriculture and manufactures, there is some reason to believe that the depressed condition of manufacturing industry is largely bound up with the misfortunes that have overtaken the farming community. The farmers of Great Britain are estimated to have lost some 200 millions, or about one-half of their entire working capital, during the last ten years. This, again, signifies that they have not had the means with which to purchase agricultural implements, domestic requisites, and many other items which they could afford when their trade was prosperous. The future of the agricultural interest is far from hopeful. It could be materially improved by higher prices for produce; but these higher prices do not appear to be probable in face of the increasing competition between our own Colonies, India, and America for British markets. Some optimistic and speculative minds have been seeking to solace themselves with the belief that, by-and-by, the United States and India will themselves consume all the food that they can raise; and others are content with the more proximate satisfaction that this year's harvest will not allow of the same surplus for export in the chief wheat growing countries of the world.

The future of prices is necessarily determined by two leading considerations: the first, that of how cheap raw materials can be bought; the second, that of how economically we can produce. There is a third element that has always a great deal to do with the question, viz., that of the character and extent of the competition that our manufacturers have to meet, both at home and abroad. There does not appear to be any solid reason to anticipate that we shall have a materially higher price to pay for the raw materials of our manufactures. The area of supply for the majority of materials is continually widening, and this alone is a sufficient guarantee that prices will not be greatly advanced, except under very exceptional circumstances. Our manufacturers, however, are evidently increasingly subject to a keen competition on the part of other nations in manufactured commodities. Our imports of manufactured goods during 1887—including metals, which are more or less manufactured—amounted to about seventy millions sterling, being nearly 20 per cent. of our total imports of all kinds in that year. This is, no doubt, good for the general consumer; but it is far from satisfactory to the manufacturer, who, under a free, fighting trade, finds it more and more difficult to keep his head above water, and for whom the only possible hope of salvation seems to lie in the utmost economy in every direction.

There is one remarkable feature of the depression from which we are now beginning to emerge, and that is that it has been literally world-wide. England has only been an exceptional sufferer in so far as her commerce and manufactures are on a larger scale than those of other countries. With hardly a single exception, the export and import returns of all other countries show a shrinkage as well as our own, and even our Colonies are not exempt. In most of the Colonies, the trade done during the last two or three years has been considerably under that of some previous years. Continental agriculture has suffered like our own, but not with equal reason, seeing that the majority of European nations levy tariff duties on imported bread stuffs, while ours are absolutely free. Other nations have, in isolated cases, made remarkable strides in particular industries; but this has been so rare an event as to have provoked a greater amount of observation than it could fairly claim. England still continues to produce the cheapest manufactured commodities in all the leading industries of the world. We produce the cheapest coal, the cheapest iron ore, the cheapest iron and steel, the cheapest machinery, and the cheapest cotton, quality for quality. If we continue to do this—and there is no reason to apprehend that we shall fail—we are sure to hold our own in the home market, and in the markets of the world.

The auguries for the future are, however, by no means so harmonious as we should wish them to be. There are still very grave apprehensions that we are on the eve of a huge and desolating European war. Why there should be such a war is a problem that no one seems to think it necessary to solve. The armaments that are now maintained at enormous cost by all the leading nations of continental Europe are in themselves a standing menace to the peace of the world. With all respect to the ancient aphorism that the best way to preserve peace is to be prepared for war, it is not justified by results; and there is a growing disposition to believe that the people who are taxed for the maintenance of the enormous standing armies of the Continent will not be satisfied to keep up this taxation unless they see some fruits accruing therefrom. In the case of France, retaliation on Germany is perhaps a sufficient object; whilst in Germany there is profound belief that it is necessary to keep up armaments that will be more than a match for those of France. Austria-Hungary and Italy have each their own theories as to their dangers and necessities, and the "Colossus of the North" has, by repeated aggressions, and by the discordant character of the elements that compose the Russian Empire of to-day, become so much of a menace to Europe, and so liable to internal troubles, that it is probable that disarmament would involve dismemberment, if not more serious disaster. It is regarded in some quarters as probable, for these and other reasons, that a European war is an event of the near future. It is owing to this feeling of uneasiness that the revival of trade, which has undoubtedly commenced, will probably not attain the large proportions usual after a prolonged period of depression. Thus we enter upon 1888 with better hopes than could be entertained in the beginning of 1887, but hardly with a greater feeling of confidence in the stability of the situation.

Political considerations are, however, at the present moment not the only disturbing factors in the prosperity of English industry and commerce. Internal

Digitized by Google

difficulties regarding the relative positions of employers and employed are unfortunately an ever present danger to the prosperity of our great manufacturing community. Of late there has been a good deal of dissatisfaction on the part of large employers of labour with the current rates of wages, which seem out of proportion to the interest realised by capital on manufacturing operations. So far as capital is concerned, there has been a tendency for a number of years towards a lower level of safe interest. The price of Consols, and the high premiums at which the shares of our leading railway companies are quoted, would appear to prove that secure investments paying more than 3 per cent. are becoming increasingly scarce in this country. In the case of a successful business enterprise, the earning power of capital, with some amount of superintendence added, may occasionally rise as high as 10 per cent.; but that is now the exception where it formerly was the rule. The capitalist naturally regards this state of things as unsatisfactory, and is apt to regard a reduction of wages as a fair and proper remedy. This view is strengthened by the fact that wages have generally been increased concurrently with a remarkable reduction in the value of commodities over the last thirty years.

The President of the Institution of Civil Engineers, in his address, referred to the rise of wages paid to engine fitters as a proof that during the last fifty years their position has greatly improved. According to Mr. Bruce, the wage per hour has in that interval increased by about 26 per cent. At the same time, many commodities have fallen by 20 or 25 per cent., so that skilled artisans are now very much better off than formerly, whatever may be the position of the unskilled labourers. At the same time, the return to capital has been reduced from 10 or 12 to 3 or 5 per cent., and in this discrepancy between the rewards falling to the two wealth-producing factors lies the danger. As wages cannot be reduced without impairing the quality of the manufactured articles, and thus injuring the trade generally, to say nothing of the personal hardship inflicted on the artisan, capital will seek for fields where it can obtain a larger return—in other words, it will be gradually withdrawn from such British industry as fails to reward it adequately, and transplanted to foreign countries. This movement has to a certain extent already taken place during the past year, and there are indications to show that it will go on during the present year to even a larger extent.

THE COMMERCIAL DEVELOPMENT OF SHIPPING AND SHIPBUILDING.

I.

THERE is nothing in the history of industry that is invested with a greater degree of interest to a maritime nation like our own, than the development of shipbuilding and its consequent effect on the commercial position and prospects of different nations. To Great Britain, as the shipbuilder of the world, this record is, and must always be, peculiarly interesting. We have achieved a position in the carrying trade of the world that has never been attained by any other nation. Our shipbuilding interest is thereby placed in the very front rank. We produce a greater tonnage of new shipping every year than all the other nations of the world put together. This is an economic problem of very great importance, and it naturally divides itself into the two considerations, viz.: (1) How has England come to occupy its unique position as a shipping and shipbuilding nation? and (2) Is it probable that that position will be maintained in the future?

The shipping and transport trade of the world has from time to time been subject to great changes and vicissitudes. These are naturally so much a part of the domain of ancient history, that we cannot give much attention to them here. In the seventeenth century the carrying trade of the world appears to have been divided between Holland, Spain, and England. During the war between Holland and Spain, the latter country lost the greater part of her naval power. Between the years 1643—when the treaty of Munster was concluded between these two continental powers—to 1698 the commerce of Holland is estimated by De Witt to have increased by about one-half, and Spain was at that time forced to hire Dutch ships to sail to her American possessions. Holland had then, according to Sir William Petty, about 900,000 tons of shipping, or about one-half the total tonnage of Europe. The Dutch almost monopolised the shipping trade for nearly a century afterwards, not as a result of any artificial monopoly, but by reason of the greater number of their ships, and their superior skill and economy in navigation. In 1701, when Holland was at the zenith of her naval power, inquiries were addressed by the Commissioners of Customs to the officers at the different ports, which showed that the whole mercantile navy of England amounted at that time to no more than 261,222 tons, carrying only 27,196 men and boys.

The remarkable feature in the shipping and shipbuilding supremacy of Holland during a great part of the seventeenth and eighteenth centuries was that that country had no conspicuous natural advantages for the prosecution of either industry. The Dutch had, indeed, scarcely a piece of timber fit for shipbuilding purposes, and they had no native produce to export worth speaking of. The principal centre of the Dutch shipbuilding trade was Swaardam, a place that has since been of very little account. It was by the force of industry, the close cultivation of colonial resources, and the economy and skill with which all operations of a commercial and industrial character were carried on, that Holland so far "breasted the blows of circumstance" as to secure the position that Great Britain subsequently wrested from her. The same readiness to grapple with natural obstacles has been apparent in more recent times. Even now, although Holland produces neither iron nor timber, a considerable shipbuilding industry is carried on at the principal Dutch ports. The merchant navy of Holland, on the other hand, is now not more than one-half, as measured by tonnage, that it was in the seventeenth century. This decay has been attributed to the natural development of commerce in other countries, and to the pressure of taxation at home.

The expansion of English shipping and shipbuilding has been dated, by some writers, from the adoption, in 1651, of the famous Act of Navigation. That of France has been attributed by others to the promulgation of the tariff of 1664 by M. Colbert. The effect of these measures, however, cannot have been very immediate, since Sir William Petty gave the tonnage of English shipping in 1690 at less than half a million of tons, and that of France at only 100,000 tons. These, and all other returns up to within the last half century, are, however, very conjectural. The truth of the matter is, that although the Custom House authorities professed to keep returns of the mercantile marine, they were vitiated by the fact that the law did not compel these vessels to be registered that plied only within the limits of a port. The inaccurate and imperfect character of the official returns caused the committee appointed by Parliament in 1839 to investigate the causes of accidents on steamships, and institute a special inquiry into the extent of the then shipping industry, and they found that there were 760 steam vessels in Great Britain and Ireland having a registered tonnage of 78,884 tons, and 56,490 h.p. Of these, 256 were under 50 tons burthen, 145 were between 50 and 100 tons, 84 were between 100 and 150 tons, 76 were from 200 to 300 tons, and 41 were between 300 and 400 tons. Only twelve vessels in all were over 400 tons burthen.

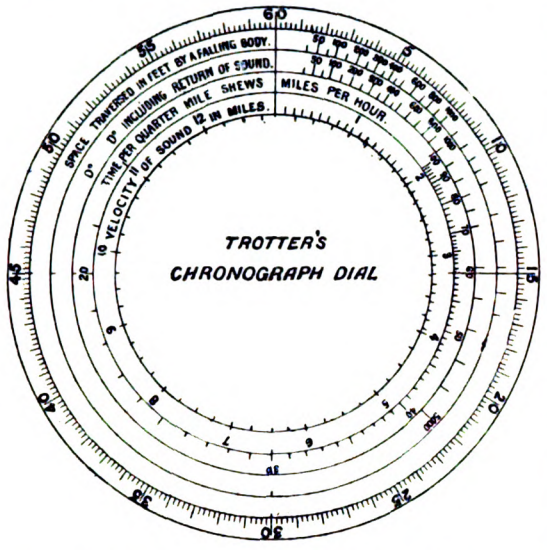
The effect of the introduction of iron in the place of timber has been to shift the *venue* of the shipbuilding trade in this country, and to give it a special stimulus in localities where iron was cheap and plentiful. In the days of "wooden walls," vessels were largely built in the South of England—at Woolwich, Gravesend, Dartmouth, Portsmouth, and Southampton. The Clyde, the Tyne, the Wear, and the Tees—the modern centres of the trade—were then almost of no account. But these northern rivers took the lead when iron became the dominant material, and they have kept it ever since. This is especially true of the Clyde. Commencing with the construction of the "Comet," constructed by Henry Bell, in 1812, for the transport of passengers between Glasgow and Greenock, the Clyde has ever since kept to the front in marine architecture. In 1864, indeed, there were 178,000 tons of new shipping constructed on that river, out of a total of 461,000 tons launched in the United Kingdom as a whole. But even these figures do not adequately show the relative superiority of the northern river, for most probably at least three-fourths of the tonnage launched in that year on the Clyde would be iron steamships; and as the total tonnage of steamers built in the United Kingdom in that year was only 186,000 tons, the Clyde manifestly did by far the lion's share of this kind of work. Taking an average of the last twenty years, the Clyde has contributed nearly one-half of all the shipbuilding of the country. In some years, as in 1881, when the proportion falling to the Clyde was 327,000 tons, out of a total of 608,000 tons built in the country as a whole, the shipbuilders of that river have contributed more than one-half of the whole.

It goes without saying, that during those earlier days of the iron shipbuilding trade the business was fairly prosperous. This fact called into existence a great expansion of the trade, chiefly on the Tyne, Wear, and Tees; but also, to a less extent, at Dundee, at Leith, at Grangemouth, and at Belfast. Other localities of minor importance came into the field; and by the year 1880 there were upwards of thirty distinct ports or localities in the United Kingdom at which ships were being built of iron or steel. The main difference between one port and another, in an economic aspect, was that involved in questions of transport. Obviously, all other conditions being equal, the Tyne, Tees, and Clyde, which are in the neighbourhood of great iron works, providing the materials used at the cheapest possible rate, should have advantages over districts that had to import their materials over longer distances. But this, after all, cannot be the sole determinant of success, otherwise the iron shipbuilding trade at Southampton and Belfast would be brought to a standstill, whereas it has for years past been in a very flourishing condition. The most flourishing and progressing centres of the shipbuilding industry at present appear to be the Tyne and the Tees. A few years ago, those rivers came very far behind the Clyde in their united production. Now, however, they unitedly produce about as great a tonnage as the more northern river.

In a survey of the general economic progress of shipbuilding, it is necessary that we should direct our attention to other countries than our own. In so doing, our first glance will be cast at the United States, which have had a remarkable record. About 1861 the total tonnage of the shipping of the world was, according to a high authority, thus distributed:—

Belonging to the United States.....	5,539,000	tons.
" the United Kingdom	5,895,000	"
" all other countries	5,800,000	"

The tonnage of shipbuilding turned out of the United States ports at this time often exceeded that produced in the United Kingdom. The material employed was, of course, chiefly timber, and the class of vessels built, the famous clipper ships of that day. America could keep her own so long as timber-built vessels were the order of the day. When iron took the place of wood the condition of things were changed. The tariff of the United States did not allow of iron being imported, except on the payment of almost prohibitory duties, and with labour very much more costly, the shipbuilding trade of the American Continent rapidly decreased. This movement was greatly accelerated by the events of the civil war, which, for a time, almost stopped the production of American-built vessels, and caused the trade to be transferred to England. The American shipbuilders now turn out, on an average, about one-third the tonnage annually built in Great Britain. They chiefly, however, build wooden vessels. The tonnage built in iron has never in any one year exceeded 40,000 tons, being approximately about one-sixth of the whole production, whereas in the United Kingdom the new work turned out is almost exclusively in iron or steel. Many attempts have been made to revive the shipbuilding industry of the United States. Remissions of tariff duties have been made on iron imported for shipbuilding purposes. Bounties have been proposed. Foreign vessels have been entirely excluded from the internal commerce of the country. But these, and other devices of the same kind and tendency, have alike failed to restore the American shipbuilding trade to its former prosperity, and for many years past the Americans have had the mortification of seeing about 90 per cent. of their over-sea trade carried in British-built and British-owned bottoms.



The case of Continental countries has not been much more satisfactory to themselves than that which we have just cited. From time to time we have been accustomed to hear it said that the shipbuilding supremacy of our own country was in serious danger. We have no wish to be unduly optimistic, but the figures show that if our shipbuilding industry is not unassailable, it has not so far been successfully assailed. The tonnage of vessels launched in France has not, in any year since 1873, exceeded 60,000 tons, and if we except the years 1882 and 1884, it has never exceeded 40,000 tons. In Germany the trade has made somewhat more progress, but even there the greatest tonnage launched in any one year has been under 85,000 tons, or less than one-fifth our own average over the last ten years. Italy, the only other shipbuilding country of any note, has never been able to supply her own requirements, small as they are.

The causes of the supremacy of British shipbuilders are not far to seek. They are to be found in a plentiful supply of cheap raw materials, including in that term iron or steel and timber; in the superior efficiency and industry of British labour, in our splendid seaboard, with its admirable harbours, and every facility both for building and launching ships; in the superior scientific knowledge of our naval architects, and in our unquestionable prestige and repute as a shipbuilding nation. Whether these advantages will ultimately be wrested from us, or shared in a material degree by other nations, we do not venture to say. Hitherto, at all events, they have been retained almost exclusively.

TROTTER'S CHRONOGRAPH DIAL.

THE annexed sketch illustrates an ingenious dial, devised by Mr. A. P. Trotter, for use in stop watches. By the addition of this dial to an ordinary stop watch, the latter can be employed for determining the distance traversed by a falling body, by observing the time occupied between the moment of release and the moment it strikes the ground, or with an appropriate allowance for the speed at which sound travels, by observing the time from the moment the object is released until it is heard to strike the ground. The distances can be read off on the second and third circles of the dial respectively. The first or

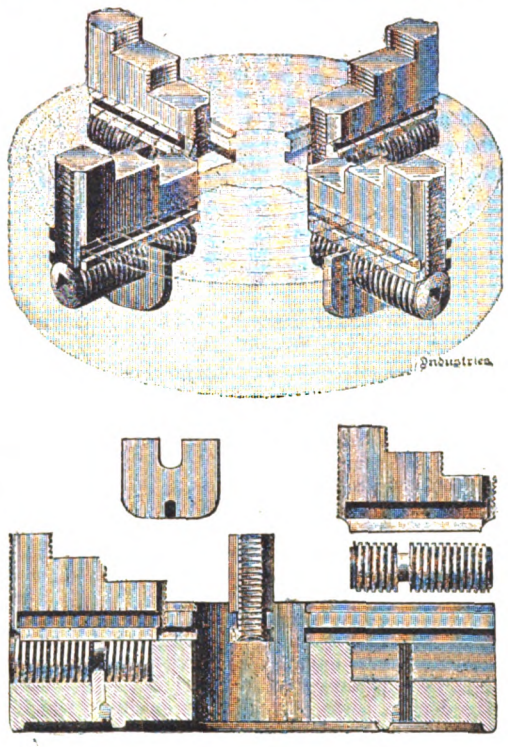
outermost circle gives seconds, as in the usual chronograph dial. The second and third circles are only marked up to the depth a freely falling body would reach in eight or nine seconds, because for greater distances the velocity acquired by a falling body becomes so great that the air resistance sensibly affects the time occupied in falling a certain distance; and as the air resistance depends on the size, shape, and weight of the body, it is impossible to make a general allowance for this disturbing effect. The dial has therefore been marked only so far as 1000ft., which limit will probably suffice for all practical purposes. The fourth circle shows miles per hour when the second hand is started when entering upon and stopped when completing a quarter of a mile. The fifth or innermost circle shows the distance in miles corresponding to the interval which elapses between the flash of a gun and the arrival of the sound. Mr. Trotter's ingenious and inexpensive addition to chronographs and stop watches should prove of great value to engineers.

SHIPBUILDING NOTES.

Messrs. Pearce Brothers, Dundee, launched this week for a Japanese syndicate in this country, the first of a fleet of passenger screw steamers for traffic on the Japanese coast. She is expected to run at a speed of 14 knots an hour. The steamer was named the "Anshin-Maru."

The s.s. "Karagda," built for the British India Steam Navigation Company by Messrs. A. & J. Inglis, underwent steam trials on the Clyde a few days ago. The "Karagda" is a vessel of about 1170 tons. The speed obtained was 13·85 knots on extended trials.

The s.s. "Damascus," built by Messrs. R. Napier & Sons, Glasgow, for Messrs. George Thompson & Co., of Aberdeen, underwent a trial last week. The "Damascus" is a vessel of 3800 tons gross, and is fitted with triple expansion engines of 3000 h.p. The mean speed attained on the measured mile was 14½ knots. The "Damascus" is intended to be used in the Australian and China trade of Messrs. Thompson.



On December 29th, 1887, there was launched from the yard of Messrs. Jos. L. Thompson & Sons, Sunderland, the steel steamer "Cabo San Antonio," built to the order of Messrs. Ybarra & Co., Seville. The vessel is of the following dimensions: Length, 260ft.; breadth, 36ft.; depth, 23ft. 6in.; and it has been constructed on the longitudinal or cellular bottom system, under special survey of the highest classification. The principal saloon will be handsomely furnished, the floor being laid with encaustic tiles. The "Cabo San Antonio" is being fitted with triple expansion engines of 700 i.h.p. by Messrs. Blair & Co., Limited, of Stockton-on-Tees.

Messrs. Short Brothers, Pallion, have apparently determined to have as favourable a return for tonnage built in 1888 as possible, as they began the year with launching, at 4-0 a.m. on the 2nd inst., the steel steamer "Scottish Prince," built to the order of Messrs. Knott Partners, Newcastle-on-Tyne. The "Scottish Prince" is a vessel of 1954 tons gross register, length 290ft., breadth 38ft. 9in., depth moulded 20ft., and is to be fitted with a set of triple expansion engines of 180 n.h.p., by Mr. John Dickinson, of Palmer's Hill Works. The boilers are of steel, 150lb. working pressure. This is the seventh vessel built for the same owners by Messrs. Short Brothers during the last three years.

A handsome iron sailing ship, the "Afghanistan," was launched last Thursday for the British and Eastern Shipping Company, Limited, of Liverpool, from the yard of Messrs. Richardson, Duck, & Co., of South Stockton. The following are the principal dimensions: Length, 305ft.; breadth, 42ft.; depth of hold, 24·7ft.; registered tonnage, about 2200 tons. She is rigged as a four-masted barque, with full poop aft, with saloon and accommodation for captain and officers. This is the sixth ship built for the company.

REVERSIBLE JAW CHUCK.

WE are indebted to our contemporary, the *American Machinist*, for the accompanying illustrations showing a new independent reversible jaw chuck invented by Mr. D. E. Whiton, and manufactured by the D. E. Whiton Machine Company, New London, Connecticut. The chief part of the chuck consists of a casting fitted with radial slots open on both ends, beneath which the screws for working the jaws are fitted. The screws are provided with a groove near the middle, into which a U shaped plate of

hardened steel fits, and which is inserted through a groove at the back of the chuck after the screws are in position. This steel plate takes the horizontal thrust of the screw. The advantages claimed for this chuck are: Work of larger diameter than the chuck can be held, as the thread of the screw extends to the outside of the chuck; the thrust in the screw is entirely taken by a hardened steel plate, thereby reducing the wear; the screws may be easily removed or replaced, but are safely held in their places while the chuck is working; the screws and jaws are made of bar steel, and the jaws are hardened and easily reversible.

SCHOOLS OF FORESTRY IN GERMANY. By J. C. Brown, LL.D. Edinburgh: OLIVER & BOYD. London: SIMPKIN, MARSHALL, & Co. 1887.

Forestry as a branch of industry has not received the same attention in this country as it has on the Continent, where for many years there have been fully equipped schools for the training of men who were intended to take charge of the plantations belonging to their respective Governments or to private individuals. Until a few years ago those intended for the forest service in India were sent to Spain, France, or Germany for their training, while those in charge of the forests of this country or the Colonies picked up their knowledge in the same haphazard manner as apprentices in other businesses usually do. Considering the importance of the subject, this is very much to be deplored, for not only is timber absolutely necessary in every description of architecture and rural occupation, but trees in a living state have a very important effect on the climate, by yielding shelter to lands exposed to rough winds, and shading those subject to burning sunshine. Attention has now, however, been directed to the matter, and a Select Committee of the House of Commons, which was appointed to consider whether by the establishment of a Forest School or otherwise our woodlands could be rendered more productive, has recently issued its report. Notwithstanding this, the book which has been written by Dr. Brown is likely to be useful, for the author has had a very large and varied experience in different parts of the world, and has recorded his experience in a long series of works. Four years ago, at a public meeting held in Edinburgh and presided over by the present Secretary of State for Scotland, it was resolved that it was expedient in the interests of forestry to promote a movement for the establishment of a National School of Forestry in Scotland, with a view to furthering and stimulating the scientific management of woods in Scotland and the sister countries. As a result of such movement it was decided that an International Exhibition of forest products and other objects of interest connected with forestry should be held in Edinburgh. The exhibition proved a great success, but as yet no definite steps have been taken for the establishment of the school; in fact, with the exception of a few classes in the Indian Engineering College, no instruction is given on the subject in Britain. Dr. Brown points out how some of our existing institutions might be so modified as to admit of forestry being taken up in them, and that at a comparatively small outlay, and his book is intended to give an idea of the nature of the instruction which ought to be afforded. It begins by giving a short outline of the history of what may be called scientific forestry, and then enters into descriptions of the more important schools of forestry in Germany, such as the Royal Saxon Forest Academy in Tharand, the Royal Prussian Forest Academy at Neustadt-Eberswalde, the Royal Hanoverian Forest Academy in Munden, and others, as well as an account of the courses of instruction in forestry in various polytechnic schools; and the concluding chapter is taken up with an account of the relation of the schools of forestry to the national system of education in Germany, and with some of the financial questions connected therewith,

Digitized by Google

while an appendix gives a considerable amount of information and a number of suggestions which would be useful in organising a British National School of Forestry. We trust that Dr. Brown's book will advance the object he has in view, and we recommend it to those of our readers who are interested in forestry.

THE ENGINE, BOILER, AND EMPLOYERS' LIABILITY INSURANCE COMPANY, LIMITED — CHIEF ENGINEER'S REPORT FOR 1886.

The report of Mr. Michael Longridge for the year 1886 practically forms a short treatise on the safe and economical working of steam engines and boilers, apart from its value as a record of useful inspectional work, which just now has an important bearing on past and prospective legislation. In the report is a summary of defects which have been discovered during the year in engines and boilers coming under his company's inspection, whilst a large space is devoted to an analysis of the Board of Trade Reports on boiler explosions. It also contains some interesting remarks on the proposed boiler legislation. The total number of accidents of all kinds to engines is rather below the average for the previous seven years; but the insurance of engines is a matter in which, even with careful and periodical inspection, there will always of necessity remain a large element of risk. It is interesting to note that whilst 37 per cent. of the accidents to engines were due to causes purely accidental or unascertained, 30 per cent. were ascribed to weakness and faulty design, though Mr. Longridge remarks that "as regards the latter class it is but fair to say that in many cases the fault lies not with the designer and builder, but with the owner, who, to avoid expense, persists in using pressures and speeds which the engine was never designed to bear."

There is the usual lists of defects in boilers which have been discovered by inspection, under the head of corrosion, fractures, &c., and mountings either out of order or altogether inoperative; but it is gratifying to learn that during the year there has been no explosion of a certified boiler. A boiler, however, which was insured by the company but not certified, ruptured in the fire box, which was much weakened by corrosion. With regard to this, it is explained that "as the boiler, notwithstanding repeated applications on the part of the company, had never been prepared for thorough examination or certified, the company does not consider itself in any way, except pecuniarily, responsible for the damage." During the year the Board of Trade have investigated and reported on fifty-five explosions of boilers and other vessels working under steam pressure, causing the death of thirty-two persons, and injury to sixty-one others. The chief feature of Mr. Longridge's report, and that which will have an especial interest for the steam user, is the chapter on "Boiler Legislation." After specifying the object of the draft Bill which it is proposed to submit during the next session of Parliament, the writer proceeds to examine each of its provisions, and to point out the consequences they appear to involve. He then goes on to consider whether the interests of the public demand such a stringent measure, and whether, if carried out, it is likely to be successful in its operations. He calls attention to the fact that most of the proposals contained in the Bill are embodied in the boiler laws of France and Germany, and yet the rate of explosions in these countries is higher than in England, and generally concludes that except in making the existing Boiler Explosions Act of 1882, more effective, and in that way bring reckless and wilfully negligent boiler owners under full legal control, no further legislation is required. Altogether Mr. Longridge's report is, as usual, well worth the close attention and careful study of all interested in steam power.

EXPANSION OF STRUCTURES BY HEAT. By John Keily, C.E. London: CROSBY LOCKWOOD & Co.

In his preface Mr. Keily says: "A bare record of experiments and observed facts would be but of little use to a student, or an engineer, who might not have time to study them and to frame a theory from them. To be useful, it is necessary to connect the facts together, and to show how far they are applicable to ordinary engineering practice." A well meant attempt to do this, "simply and comprehensively, by means of ordinary geometry," is contained in the subsequent pages, and from the author's point of view the attempt is fairly successful. But in a book of this kind something more than success in this narrow sense is expected, for there is little in it which an engineer or a student with elementary attainments in science could not work out for himself with a little trouble, and the principal use of such a book is to save that trouble by placing the facts and propositions in connected sequences, as Mr. Keily says; but also to state both the facts and the theories with perfect lucidity, and to work out the proofs with unquestionable and complete reasoning. In these latter respects the book before us is so deficient, that we fear that many would-be readers will find it easier and more satisfactory to work out their own conclusions than to seek help in its ambiguous and apparently illogical language. As the author appears to be master of his subject, we conclude that he is quite inexperienced in imparting his knowledge, which inexperience, combined with an over anxiety for conciseness, will explain most of the faults of his work, which, for the most part, reads like a student's note book, intended to be intelligible only to the particular student who compiled the notes. After a short preliminary section, the subject matter of the book is defined as the second of the two classes of changes caused in metallic bodies by changes of temperature, viz.: "The changes which take place in the position of the body." It is not apparent why "position" is used instead of "dimensions." The expansion of single bars leads to that of simple frames, and that to the expansion of complex frames and plates. Section V., dealing with "Thermal conductivity," has some unsatisfactory passages; for instance, "When a metallic bar . . . is exposed to the direct action of the sun's rays" it "becomes heated more rapidly than the surrounding atmosphere, because it is a better conductor of heat than the atmosphere." Sections VI. and VII. treat of elasticity, tensile strength, force of expansion, effect of heat on strength, set, flow of metals, and work of expansion and contraction; and the last section is given to suspension bridges. Section II. has articles on surveying chains and india-rubber; the last page is headed "Breech loaders in the Soudan," and immediately preceding it is a note of some observations on sea water. The omission of these subjects would not injure the book. As a general view of the effects upon structures of changes of temperature, the book may certainly be found useful by many students and practitioners of civil engineering, and we shall be glad if a demand for a second edition gives the author an opportunity of making it acceptable to a much larger number, by amplifying many passages and proofs, by distinguishing more clearly between assertions based on experiments and deductions therefrom, by the correction of such expressions as "the temperature of heat," "the principle of the centre of gravity," &c., and by the expunging of irrelevant matter.

STUDIES IN MACHINE DESIGN. By C. F. Archer. London: GRIFFITH, FARREN, OKEDEN, & WELSH.

These "studies" consist of twelve sheets of machine drawings intended for re-drawing to a different scale, in order to give students facility in drawing and familiarity with the general construction of the parts of a steam engine. There are two series of six drawings each, corresponding, we presume, with the requirements of the Science and Art Department examinations in the elementary and advanced stages respectively. The "elementary" series includes drawings of general engine details, such as bolts and nuts, couplings, joints, and valves, while the "advanced" series comprises a complete set of drawings relating to a launch engine. The drawings are well adapted to give a clear understanding of the principles underlying steam engine design, without confusing the student by unnecessary complexity; but as regards some of the details, there is a want of exactness which, unfortunately, may be frequently noticed in this class of drawings.

MINUTES OF PROCEEDINGS OF THE INSTITUTION OF CIVIL ENGINEERS. Vols. LXXXIX. and XC.

Volume LXXXIX., like most of its predecessors, contains much matter of interest, not merely in the papers read with a view to discussion, but also in the "other selected papers." The first paper in this volume is that by Mr. J. J. Webster, on "Dredging Operations and Appliances." The author gives a concise account of the various systems followed and appliances used in dredging, supplemented by particulars, collected from various sources, and partly based on his own experience, of the cost of dredging operations under various conditions, and also of the power required. With the help of a large number of indicator diagrams from engines working dredges, he establishes a simple formula for ascertaining approximately the indicated h.p. required for dredging different kinds of material under varying conditions of lift. This formula takes the shape of $i.h.p. = C.W\sqrt{H}$ where H is the height of the top tumbler shaft from the surface of the ground to be dredged, and W the number of tons per hour to be removed; C is a constant depending on the nature of the ground.

Next in order is a paper by Colonel E. Maitland, R.A., on "The Treatment of Gun Steel," which for various reasons excited considerable interest, and gave rise to an animated discussion. The latter was by general consent not limited to steel as applied to guns only, and many of the speakers handled the subject from a more general point of view. An abstract of this paper was given in our issue of the 18th March last (see *Industries*, Vol. II., page 269), so that we need not do more now than refer to that notice for details of the paper.

A very considerable portion of the discussion appears to have been devoted to the two questions of whether the ultimate strength or the elastic limit should form the basis for determining the admissible stress, and whether oil hardening be beneficial and necessary or otherwise. Major Mackinlay opened the debate, and after criticising the somewhat loose manner in which the author had employed the terms strain and stress, proceeded to explain briefly the principles involved in the building up of a gun. As we have recently had occasion to quote Major Mackinlay's own work on this subject, we shall not now again refer to the matter. Sir Frederick Bramwell supported the author's views as to the value of the elastic limit; "it was commonly said that if the elastic limit were passed the material was being destroyed;" "but as far as he (Sir Frederick Bramwell) was concerned, he did not know what the elastic limit was," as the so-called elastic limit could be raised, as stated by the author, by successive applications of stress. Sir Frederick remarked that, "if the ordinarily received views about the elastic limit were correct, then wire guns . . . must, as regarded the essential material of which they were made, viz., the wire, be every one ruined before they were made." He proceeded to explain his meaning by pointing out that wire or ribbon was manufactured by means of the draw bench, and that it "was so much strained in the act of drawing that permanent set was put into it, and it came off in the circular hank, the recognised trade form of wire;" this must mean that its power of recovery had been destroyed because the elastic limit had been passed, and it remained in a circular hank. This alone, the speaker contends, ought, according to the views of the mathematician, to ruin it, apart from the subsequent treatment it might receive in the process of application to gun construction. Professor Unwin replied very effectively, and, as we think, conclusively, to the contentions of the author and Sir Frederick Bramwell on the subject of the elastic limit. The matter is so important that we may be excused for quoting somewhat liberally from Professor Unwin's remarks. The author in the course of his paper had taken the case of two guns, one of which was constructed of a material with an elastic limit reached at 12 tons powder presssure per square inch, and the other of a material with an elastic limit attained at 20 tons. He supposed that under the action of a series of charges the elastic limit of the 12-ton gun was raised to 20 tons, and he stated that the two guns would then be in exactly the same condition—that the gun with the originally low elastic limit would be as good as the gun which had the higher elastic limit. Professor Unwin "wished to recall the fact that up to the elastic limit of the steel the whole extension of the material did not amount to more than about $\frac{1}{1000}$th of its length. The moment the elastic limit was passed, with an increase of stress of say ¼ ton, the material stretched $\frac{1}{100}$nd of its length, and in order that it might have its elastic limit raised, say from 16 tons to 20 tons, it must be stretched $\frac{2}{100}$th of its length. Take the case of the barrel of a 13½in. gun: supposing the gun had in the bore initially a material the elastic limit of which was exceeded by the circumferential and radial stresses induced by the action of powder, then before the elastic limit of that material could be raised at all the bore of the gun must stretch $\frac{1}{50}$nd of its length; before it could be raised to 20 tons it must be stretched by $\frac{1}{25}$th of its length; in other words, the 13½in. gun must become more than a 14in. gun. He imagined that guns did not expand as much as that, and if they did not he wanted to know whether it was possible that the elastic limit after all was raised. It was not by the mere loading of a material that its elastic limit was raised, but by the stretching which followed the loading in ordinary cases. If a material were in a position in which stretching was impossible there was not a particle of evidence that its elastic limit would be raised." Apart from the question of guns it may be said that no one with any knowledge of the subject will contend that a material is necessarily ruined by being strained to a certain extent beyond the elastic limit once, or even half a dozen times, and in many processes of manufacture this must occur. The point, however, of primary importance, as has been fully proved, is that the stress in excess of that at which the elastic limit is reached should not be too often repeated. It is quite obvious, to begin with, that the stress must not be carried as far as the breaking down point, and to insure security against a practically unlimited number of repetitions of stress the latter must be kept very much below that point. Recent experiments tend to prove that the raising of the elastic limit by repetitions of stress in one sense is a somewhat unstable phenomenon, and that a blow with a hammer, or a single application of stress in the opposite sense, will suffice to reduce the elastic limit to its original condition. If such a result can be brought about by the blow of a hammer on a test piece, it seems very probable that the shock of explosion in a gun would produce a similar effect on the materials of which it is constructed, and that the improvement, if any, effected by one discharge might be neutralised by the next. As

Digitized by Google

one of the speakers at the Institution pointed out, in ordinary engineering structures, and in machinery, the necessity for keeping the stresses well within the elastic limit is dictated by the purely practical consideration that anything in the nature of permanent set is quite inadmissible as a general rule. On the question of oil hardening, another of the chief points in debate, opinions were pretty fairly divided. The author himself appears to doubt the advisability of oil hardening, and holds the opinion, shared by many of those who took part in the discussion, that it tends to set up internal strains. Among those inclined to this view were Sir Frederick Bramwell, Mr. Daniel Adamson, Mr. Riley, and Mr. B. Baker, while on the other side were to be found Major Mackinlay, Mr. Nordenfeldt, Mr. Head, Mr. Longridge, and Mr. Maxim. Those practically acquainted with the behaviour of steel can, we think, have little doubt that internal strains must be produced by oil hardening under ordinary circumstances, and the larger the masses of metal dealt with, the greater the risk from the above cause. The suggestion put forward during the discussion, that large steel guns should be cast in one piece, is a proposal on which we think few, if any, private steel makers would be prepared to act on their own responsibility. One of the strongest arguments in favour of built-up guns, is the fact that the quality and condition of the metal used are under much better control than where very large masses are manipulated.

Want of space prevents us from doing more than mention a few of the remaining papers, all of which contain matter of interest. The last paper read and discussed which appears in this volume of the "Minutes," is on printing machinery by Mr. Edward Arnott Clowes. It contains a good account of the advances made in this department from its commencement up to the present date. Among the "other selected papers" are the following: "Gas Power Compared with Steam Power," by Mr. J. E. Dowson; "Setting out the Curves of Wheel Teeth," by Mr. W. I. Last; "Further Investigations Regarding Wire Gun Construction," by Mr. J. A. Longridge; and "Recent Researches in Friction," by Mr. John Goodman, Wh. Sc. and Stud. Inst. C.E. The latter contains an account of experiments carried out in the laboratory of University College, to ascertain, among other matters, the relation existing between the total frictional resistance of a brass and the chord of its arc in contact with the journal. It forms a continuation of a paper previously read at a students' meeting by the same author, to which was awarded the Miller Scholarship.

The succeeding volume contains an unusually large number of comparatively short papers, many of which, however, bear upon the same or kindred subjects. It is an admirable feature in the arrangement and editing of the papers read before and published by the Institution, that those relating to similar matters are kept as much as possible in juxtaposition with each other, in order to facilitate comparison and reference. The first four papers, on "Chalk Springs in the London Basin," "Borings in the Chalk at Bushey, Herts," "On a Bore Hole in Leicestershire," and "The Wells and Borings of the Southampton Water Works," respectively by Messrs. J. W. Grover, W. Fox, T. S. Stooke, and W. Matthews, were read and discussed together. For the population of this country in general, and more especially of the large towns and manufacturing districts, it is impossible to overrate the importance of the subject; it is brought very forcibly home to our minds by the fact that Manchester—a town situated in a county and district abounding in streams, and blessed by nature, as a rule, with an almost too abundant supply of fluid from the clouds—has to bring the water necessary for its requirements a distance of between eighty and ninety miles as the crow flies. Mr. Grover's paper refers to the water works of Newbury, Wokingham, Leatherhead, and Rickmansworth, all drawing their supply from the chalk springs in the London basin. The difficulties connected with the water problem as affecting the population in and around the Metropolis are in many respects of a different character to those occurring in Manchester and other manufacturing districts. In both cases there is a large and increasing population; but while in the latter the natural water supply would probably be amply sufficient if not contaminated, in the former this is not the case, the district around London having comparatively few rivers, and those, with one exception, insignificant, while the rainfall is much less than in the northern counties. Mr. Grover states that in July, 1885, no less than 96,000,000 gallons were drawn from the Thames daily, being more than one-third of the entire volume of the river then flowing over Teddington weir. He looks to the chalk as the proper prospective supplemental source of supply for London. With reference to this point, the following remarks of Dr. Evans during the discussion are worth quoting: "In the case of a chalk country the whole of the water abstracted by pumping was so much abstracted from the streams, which would otherwise flow through the country. Of course, the question would arise as to the water supply, not only of the Metropolis, but of the towns around the Metropolis, and in every case where there was chalk, ... they might get an admirable supply of chalk water for the towns and villages. That water, after being used, was returned to the rivers, and practically the rivers did not suffer. But if London were to obtain the whole of its supply from the wells sunk around London in the chalk, taking Mr. Grover's figures of 160,000 gallons daily as the produce of four inches of rain on a square mile of country, London would require, instead of that, 160,000,000 gallons; and the whole of the water of the streams on 1000 square miles of country—an area considerably larger than a great many English counties—would be consumed for drinking water, and for other purposes, in the Metropolis. But he was wrong in speaking of it as drinking water. There was not the slightest necessity for any such large supply of drinking water being brought into London. There was, for ordinary purposes, any amount of water in the shape of Thames water. At present there was brought into London more than enough spring water to supply all the necessities of the Metropolis; and if he were to make a suggestion to the Institution of Civil Engineers, it would be—why not try whether some system of double service could not be adopted, rather than attempt to rob the whole neighbourhood around London of its natural water supply, and be at an enormous expense to bring pure water into the Metropolis, to flush the sewers and water the roads?"

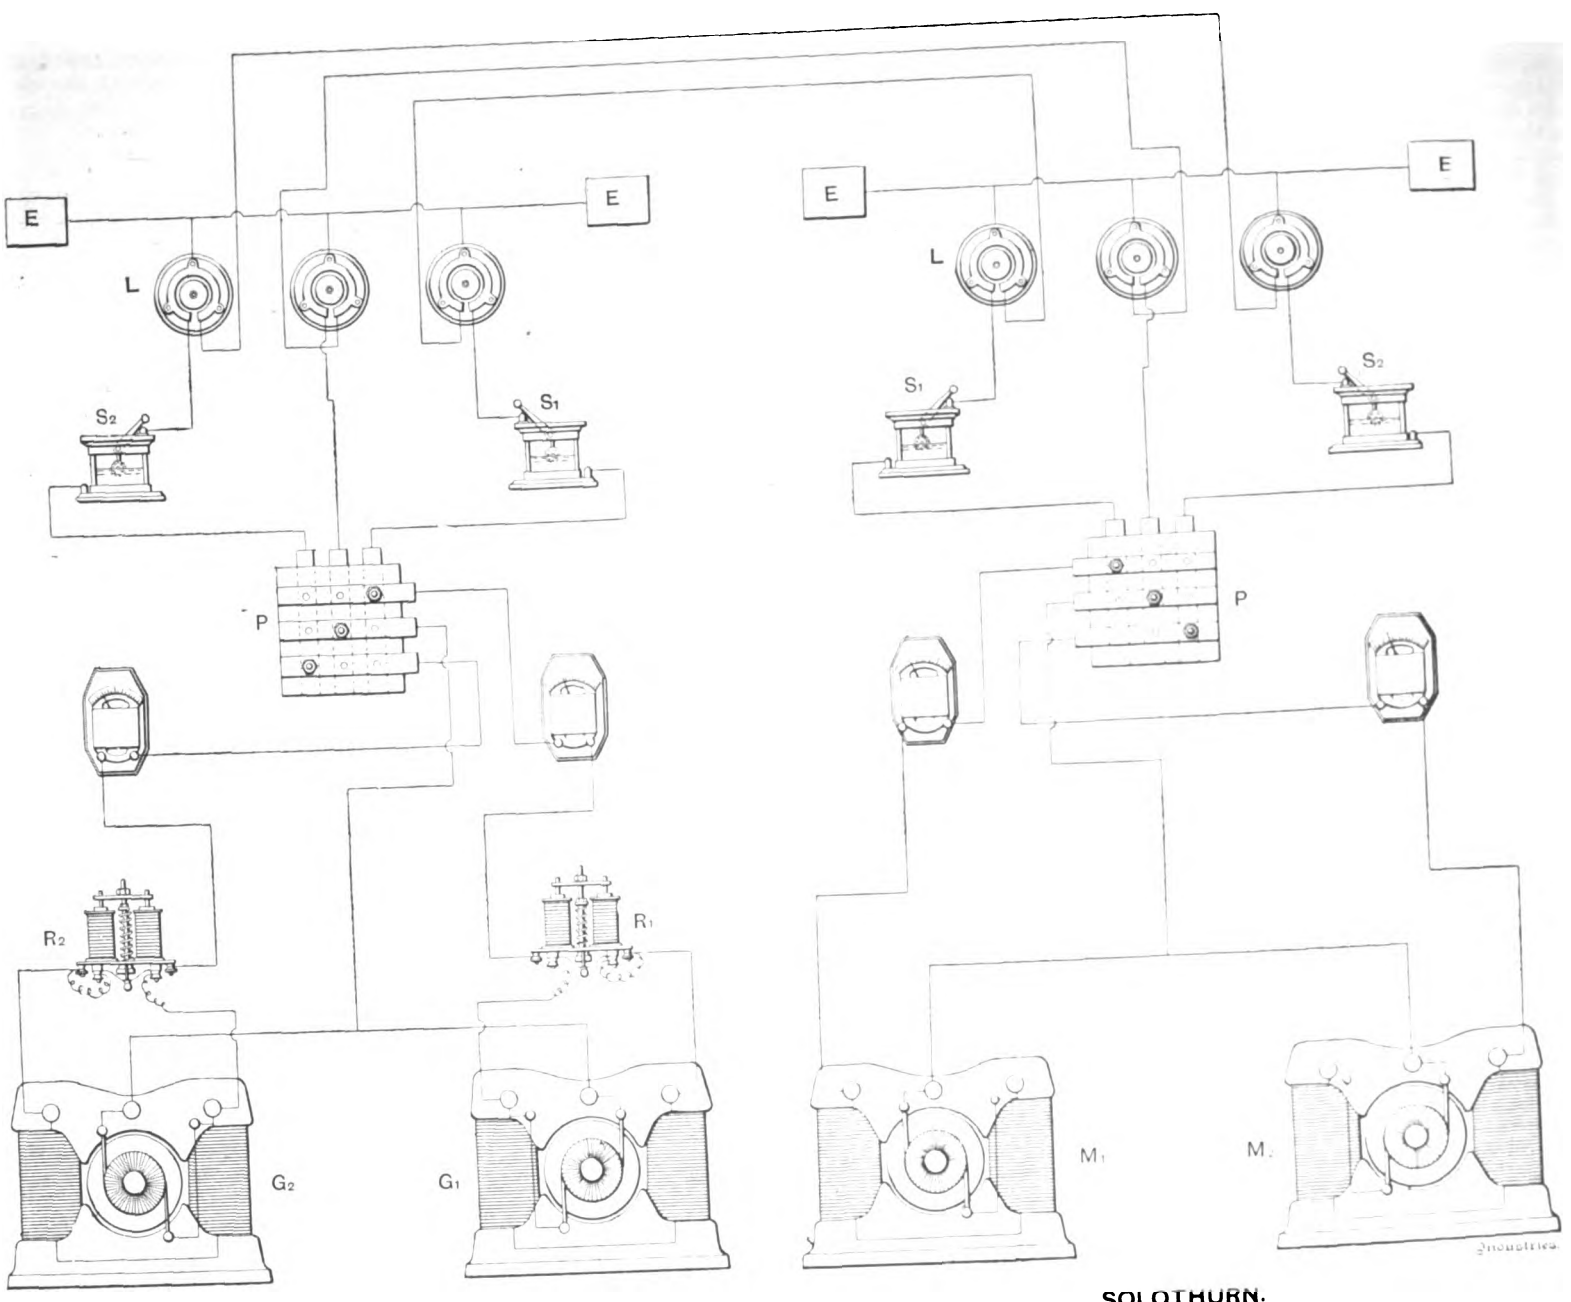
The next paper in order is that on "The Conversion of Timber by Circular Saws and by Band Saws in the Pine Growing Districts of the United States of America," by Mr. L. H. Ransome, a student of the Institution. The paper relates chiefly to the practice in the State of Michigan, of which the Saginaw Valley district turns out, according to the author's statement, more lumber than any timber producing district of like extent in the world. The largest quantity of wood ever cut in one season was in 1882, when the total reached 1,011,274,905ft. (square feet one inch thick). In the course of the paper, a very ingenious machine, called a "steam nigger," for placing the logs on the travelling carriage of the sawing machine and holding them in position while being fixed, is described; when properly manipulated, it will roll into position and fix on the travelling carriage ready for sawing a log of 16ft. long by 2ft. diam. in from three to four seconds.

As regards the speed of circular saws, it is generally considered in America that the circumferential speed should be about 7540ft. per minute, with a saw 8ft. diam. With respect to the comparative merits of circular and band saws, the circular has the advantage in rapidity of production, turning out 50,000ft. of lumber in ten hours, as against 35,000ft. for the band saw. The quality of the work produced by the latter is, however, superior and the waste less, while having been only recently introduced for this purpose it is capable of further improvement, whereas the circular saw has probably reached the utmost limits of production.

Sir Lowthian Bell's paper on the "Manufacture of Salt near Middlesbrough," describes what appears to be in that district a comparatively new industry. In 1859, Messrs. Bolckow & Vaughan commenced the sinking of a bore hole, with the object of eventually sinking a deep well to obtain water for steam and other purposes; but instead of finding what they required, came at a depth of 1200ft. upon a bed of rock salt 100ft. in thickness. After an attempt, frustrated by the large influx of water, to sink a pit and work the mineral by a regular system of mining, the undertaking was abandoned for many years, but eventually taken up again by Messrs. Bell Brothers. The salt is raised in brine, and for the evaporation of the latter the waste gases from the blast furnaces, which are in excess of what is required for heating the air and raising steam, are employed. By means of the waste heat thus utilised, from two hundred to three hundred tons per week of salt is obtained. In connection with this salt industry, the manufacture of soda by an ammonia process invented by Mr. Schloesing, of Paris, has been established.

Sir Frederick Abel contributed a very interesting paper on "Accidents in Mines." In it the various causes of accident are enumerated, statistics of casualties given, and the various means and apparatus devised for their prevention described. In regard to the detection of fire damp in mines, Sir Frederick Abel states the qualities which must be demanded of a really useful fire damp indicator, viz., simplicity of construction, facility of use by persons of average intelligence, quickness of action, non-liability to derangement, and capacity to detect less than 1 per cent. of fire damp in the air of the mine. The instrument which has hitherto most nearly approached the fulfilment of these essential conditions is the fire damp indicator of Mr. E. H. T. Liveing, in which he uses photometrically the rise of temperature produced in a platinum wire when this is heated in a mixture of fire damp and air.

Among the subjects of the "other selected papers"—all well selected—are: "Water Supply in the Cape Colony," by Mr. J. G. Gamble; "The Yanegase Yama Tunnel on the Tsuruga-Nagahama Railway, Japan," by Mr. Kinske Hasegawa; "Flour Mills and their Machinery," by Mr. Alfred Chatterton; and "The Strength of Iron and Steel in Shear and Torsion," by Messrs. Platt and Hayward.



We note that an increasing number of the papers published are by students of the Institution. The foreign abstracts are chosen with the usual good judgment and discrimination, and contain much matter of interest to all classes of engineers.

Every Man His Own Art Critic at Manchester Exhibition, 1887. By Patrick Geddes. Manchester: John Heywood.

There are some minds so singularly fertile in suggestion upon all sorts of topics that one loses in time any sense of surprise at finding them commenting with their old vigour in some new field. Yesterday they out-rhymed the laureates, to-day they re-organise a science, to-morrow they may revise the constitutions of all previous Solons. They have the true secret of versatility, which is for the most part the application of the same unvarying form or set of forms to varying matter. To those who have followed Mr. Geddes' work at all closely there will be little astonishment at finding him writing upon art and art criticism. A scientist of well earned reputation, a suggestive writer on economics and on social and industrial topics, a practical organiser of philanthropic work upon æsthetic lines, it was quite in the range of his many-sided interest to apply to art the powers of analysis and synthesis which he has so successfully employed elsewhere. The mould was already there, the fusion of the new material for pouring into it was comparatively easy. The superb collection of pictures at Manchester afforded the opportunity for the subjection of art products to the crucible of the scientific mind, and the result is an exceedingly useful primer of modern pictorial art. Of the need for such a work there can be no question. The growing desire to learn the lesson of the arts and to enter into the House Beautiful has had as yet no commensurate results. The power which should be expended in progressing along the path to it is lost in the endeavour to find the way. People exhaust themselves in fictitious enthusiasms. A smattering of knowledge about details of design and colour represents the highest level of ordinary artistic culture, just as a smattering about books passes for profound literary knowledge. Not one man in a hundred has sought to get at the centre, to start with a method which shall give stability and value to his criticisms, and which shall correspondingly increase pleasurable emotions by giving them direction and concentration. To all seeking more earnestly to get out of art its best and all its best, the brochure of Mr. Geddes will be of the greatest value. It may not be always novel; it may sometimes claim for science the discovery of truths discovered when science was still dividing its attention between casting horoscopes and concocting elixirs; it may occasionally read as though "Every man his own art critic" meant "Every man for himself, but, more particularly, Mr. Geddes for us all;" but these are small detractions from the genuine educational value of the treatise. To all intents and purposes Mr. Geddes places himself before a picture and interrogates himself audibly, for the benefit of those around him. "In the first place, then, let us take a simple interest in what and how much these painters' eyes have seen, and add this to our own experience of life and nature, to our power of intelligent vision henceforward. Secondly, we have to make out something of how they have expressed and re-arranged the impressions they took in—how they have made their colour photographs of the world into these works of art; for only when these two things are done, and we understand our painters as observers and workmen, shall we be in a fair way to understand them in their third capacity, *i.e.*, in so far as they are poets and philosophers, humorists or satirists, optimists or pessimists." The questions are familiar enough, but then the majority of men are not given to put any questions at all to themselves; still less are they given thus methodically to exhaust a subject by continuous questioning. If Mr. Geddes had done no more than enforce this habit, he would have done excellent work; but he has given the answers as they appealed to him in the cases of a considerable number of pictures, and so far furnished valuable illustrative aid to those who shall follow his example of orderly interrogation. It is needless to say that in these answers a personal note is struck, with which the opinions of other critics will not always be in harmony. Such a result was inevitable, since even in the individual the solution of to-day will scarcely be the solution of to-morrow. But the answers, whether in themselves acceptable or otherwise, are happily and strikingly conceived, and have often wider issues than concern the special matter of the moment. To men of general culture no less than to those straining after it, to art critics as well as to those fraudulently asserting themselves to be critics, the pamphlet may be heartily commended.

ELECTRIC TRANSMISSION OF ENERGY.

KRIEGSTETTEN. SOLOTHURN.

ELECTRIC TRANSMISSION OF ENERGY.

In our issue of the 8th of April, 1887, we gave an account of experiments carried out at the Oerlikon Engineering Works with a plant of two dynamos and two motors intended for the transmission of energy from Kriegstetten to Solothurn. These experiments were made by a committee of engineers and scientific men, with a view to ascertain the total commercial efficiency of the transmission plant; but as the machines were in this case placed side by side, the results could only be taken as approximately correct. It is evident that, in such an arrangement of machines and resistances erected within the limits of a covered workshop, the insulation of the circuits presents no difficulty whatever, whereas in the actual installation, when many miles of overhead wires must be used, the insulation becomes a matter of some difficulty, and atmospheric influences may also have some effect upon the performance of the plant. These considerations induced the makers to arrange for some further trials with the plant as actually installed. A committee was appointed, under the presidency of Professor Amsler, of Schaffhausen, the well known inventor of the planimeter, and the following gentlemen were members: Professor Weber, of the Zürich Polytechnic School, and his two assistants; Professor Hagenbach Bischoff, of Basle; Professor Veith, who occupies the chair of machine construction at the Zürich Polytechnic School; Herr Keller, engineer to Messrs. Escherwyss, of Zürich; Herr Lang, a manufacturer of Derendingen; and Herr E. Bürgin, of Basle, the inventor of the Bürgin dynamo. This committee have just issued their official report on the trials made on the 11th and 12th of October last with the plant as actually installed. Before quoting the results of these trials, it will be well to briefly refer to the general arrangement of this installation. At Kriegstetten there is a water power available, representing about forty actual horse power, and the problem was to carry as much of this power as possible to a mill in Solothurn, the distance being $4\frac{3}{4}$ miles as the crow flies; but, allowing for deviations, the length of each circuit may be taken as about five miles. There are at Kriegstetten two generating dynamos, and at Solothurn two motors, coupled up on the three-wire system, as shown in the above illustration. A perspective view of the dynamo was given on page 358, Vol. II. Each dynamo weighs 3 tons 12cwt., and has a Gramme armature 20in. diam. and 14in. long, the normal speed being 700 revolutions per minute. Referring to the diagram of connections, G^1 and G^2 are the generators at Kriegstetten, and M^1 and M^2 are the motors at Solothurn. R^1 and R^2 are electromagnetic switches which automatically come into action and short circuit the exciting coils in case of the current rising beyond a certain limit. This provision was introduced in order to guard against the destruction of the generator in case a short circuit should take place somewhere in the line. The current from each of the generators passes through an ammeter and then to a plug board, to which is also connected the balancing wire joining the negative brush of G^2 with the positive brush of G^1. The balancing wire is then carried direct to the middle one of the three lightning arresters L, and then to the middle wire of the line, whilst each of the outside wires is led through a liquid switch S^1 S^2, then to a lightning arrester, and to the line. Each lightning arrester consists of a circular metal disc, the edge of which is provided with projecting teeth, and situated in a concentric metal ring, the internal circumference of which is also provided with teeth, but not touching the teeth of the disc. All the discs are connected with a common earth wire and two earth plates E E. Should a flash of lightning strike the line, the current will leap across the intervening space between the teeth of the ring and those of the disc, and will thus be led to earth without passing through the machinery. The same provision against lightning is made at the motor station. The switches S^1 S^2 are of peculiar construction, and consist of a vessel containing a conducting liquid and a perforated metal ball dipping into it. When the current is to be switched off, the handle is turned so as to raise the ball out of the liquid; but the circuit is not immediately interrupted, since the liquid within the balls issues in fine streams out of the perforations, and so maintains the connection for a short time after switching off. As the liquid in the ball gets exhausted, and the streams become thinner, the resistance of the liquid connection is gradually increased to infinity, and thus causes the current to gradually diminish to zero. The line wires are supported on Johnson & Philips' patent fluid insulators, and the average span is about 1:30ft. Two sets of experiments were made. On the 11th October only one generator and one motor were tested, whilst on the 12th October both generators and both motors were tested. In the latter test the balancing wire was cut out of circuit as of no importance when, as in these experiments, it was quite easy to regulate the load of each motor so as to fairly divide the work between them.

Electrical measuring instruments were fitted up at both stations in rooms sufficiently distant from the machinery, so as not to be influenced by stray magnetism. The current was measured by large tangent galvanometers, and Thomson mirror galvanometers, standard cells, and potentiometers were used to measure the pressure. The object in measuring the current at both ends of the line was to ascertain whether any appreciable leak took place. In addition to these purely electrical measurements, obser-

Digitized by Google

vations were made at the generator station regarding the water level in the head and tail race of the turbine, the position of the regulator on the latter, and the speed of the dynamos and turbine. After the transmission trial on the 11th October was completed, the armature of the dynamo was taken out and replaced by a plain spindle provided at the end with a brake. The turbine was then started again under exactly the same conditions as were noted at the previous trial, and the power absorbed by the brake was measured. The comparison between the power thus measured and the electrical energy given out by the generator is evidently the commercial efficiency of the latter. On the following day both generators and both motors were tested in the same condition as prevails in actual practice, with the only exception that, as already mentioned, the balancing wire was cut out of circuit. This alteration, which could obviously not increase the efficiency of the whole system, was made to simplify the measurements. The power absorbed by the generators was computed on the basis of the previous day's trial from the observed conditions under which the turbine worked, whilst the power developed by the motors was on both days directly ascertained by means of a friction brake fitted to a first motion shaft common to both motors. A small correction was made for the power absorbed by this shaft when running idle. The following tables give the results as published by the committee:—

Time of trial.	Electrical efficiency.		Commercial efficiency.		Total efficiency of transmission.	Remarks.
	Generators.	Motors.	Generators.	Motors.		
11th Oct.	90·8	93·7	86 8	89·1	68·3	One generator and one motor.
„ „	90·6	91·3	86·9	87·1	68·2	
12th „	92·8	94·8	88·5	90·3	75·2	Both generators and both motors.
„ „	91·6	91·4	88·7	88·2	74·6	

An inspection of these figures will show that there is practically no loss of current by leakage on the line. In some cases the current measured at the motor station is slightly below that measured at the generator station; but the discrepancy is exceedingly small, and evidently due to personal or instrument errors, since in some other cases the current received by the motors appears to be even slightly larger than that sent out by the generators, which is obviously impossible. The second table also shows the influence of the air temperature upon the total resistance. The third table gives the power, and the fourth the efficiencies in percentages. It will be noticed that when one generator and one motor only were used, the commercial efficiency was slightly over 68 per cent.; but when both generators and both motors were used, this efficiency rose to about 75 per cent., which is clearly due to the higher voltage employed. On the whole, the result of these trials must be considered highly satisfactory, and Mr. C. E. L. Brown can be congratulated upon having succeeded in transmitting power over a distance of five miles with a loss not exceeding 25 per cent. It is needless to say that so high an efficiency could not possibly have been attained with any purely mechanical system of transmission.

Notes.

THE PROPELLING OF STEAM VESSELS.

The *Liverpool Journal of Commerce* states that one of the most startling and important inventions of the day with regard to the propelling of steam vessels is now under consideration. Should it prove successful and meet the expectations of the inventors, it will entirely revolutionise the whole of the steam service of this country; and it is stated further that one eminent firm of engineers has offered £100,000 for the patent.

SULPHUR MINES IN SICILY.

The low prices obtainable for sulphur are causing great anxiety to the owners of sulphur mines in Sicily, there having been a steady decrease for the last five years. The British Consul at Palermo states that dealers there have now to be content with a tenth of their former profits, owing to excessive production, the annual output at present being 60,000 to 70,000 tons above the ordinary consumption. The result is that enormous stocks are accumulating, and though the formation of a syndicate of mine owners for the purpose of restricting the production would probably bring about a better state of affairs, Sicilians are not inclined in favour of such a course of action.

ARTIFICIAL ILLUMINATION.

During the discussion of two papers dealing with artificial lighting, read at the recent meeting of the American Gas Light Association, Dr. Morton, the well known physicist, drew attention to a point apt to be overlooked in these days of electric and incandescent gas lighting, viz., the importance of a thoroughly diffused light, if injury to the eye is to be avoided. He said that diffused lighting, emanating from not too brilliant sources, is better in every way than that which, though equal in absolute quantity, proceeds from intensely bright points; and he referred to the paralysing effect and ultimate injury to the eye produced by frequent exhibitions of powerful naked lights of any kind. All lights of great brilliancy should be placed above the ordinary line of vision, and suitably shaded.

SUMACH.

One of the chief products of Sicily, according to a report by the British Consul at Palermo, is sumach, which appears in the English and American markets in the form of a powder packed in bags, and produced by drying and grinding the twigs and leaves of the plant. The powder serves both as a dye and as a mordant to fix other dyes, and is used also for tanning. The sumach powder produced in Sicily is of two sorts. The best is of a rich green colour and carefully sifted, is soft to the touch, smells rather pleasantly, and has a strong astringent taste. The second has these qualities in an inferior degree, while its colour degenerates and takes a reddish hue. The sumach grown in Continental Italy is much inferior to the Sicilian, and has a yellowish colour tending both to green and red. None of the inferior sorts are prepared with such care as the best Sicilian, and are known by the prevalence of unground fibres and minute chips, indicative of less pains taken in sifting. Various adulterations are practised in preparing sumach for the market—the most obvious, that of mixing it with mineral dust, can be discerned by steeping the suspected powder in water, when the mineral portions will fall to the bottom. When vegetable substances, however, are used, chemical analysis must be resorted to.

A GIGANTIC INDUSTRIAL AND COMMERCIAL CONCERN.

The tendency of the present day in industrial and commercial concerns is towards concentration of the means of production in few hands, and the abolition of middlemen in distribution. It is rumoured that a very remarkable development is about to take place, and in which a number of American and British capitalists are interested. According to current reports, the promoters intend to erect granaries, stores, pork curing establishments, and cheese and butter factories, on sites convenient to the line of the Minnesota North-Western Railway, and that all kinds of American produce, such as flour, fruit, ham, bacon, cheese, and butter, as well as live cattle, are to be run along this line to Chicago, thence by the Baltimore and Ohio Railway to New York, and a bridge is to be built connecting the mainland with Staten Island, where large docks will be constructed. From this port the products of the United States will be carried by steamers specially built for the company, and landed at Barrow-in-Furness. Here it is proposed to build alongside the docks abattoirs for slaughtering the cattle immediately after landing, tanneries for preparing the hides, and factories for making margarine out of the tallow. Large warehouses will also be erected, and from these the products will be distributed throughout Great Britain by means of retail stores, which will be opened in all the large towns, in order to supply consumers direct. It must be confessed that in these days of syndicates and corporations it is very difficult to see how in many departments of industry the single handed manufacturer is going to survive.

THE GERMAN CORN LAWS.

The German Reichstag has, after a long and extremely animated discussion, in which the Free Trade party made its influence strongly felt, raised the import duty on cereals, in response, partly to the clamour of the agriculturists for further protection, and partly in satisfaction of a revengeful feeling evoked by the fiscal policy of Russia towards Germany. The annual consumption for the whole of the German Empire has now reached, in round numbers, 400,000,000cwt. Down to the year 1866, the home production exceeded the requirements, but since that date an important import trade has sprung up, and has grown so rapidly that German agriculturists, like our own, have been driven into adverse circumstances. In the period between the years 1881 and 1884, inclusively, the imports of cereals, about one-half of which were derived from Russia, increased, on an average, by 40,000,000cwt. annually, or about one-tenth of the total consumption. As the tendency of this foreign trade manifestly was to grow at a still more rapid rate, the agricultural party became alarmed at the prospect, and raised an outcry against the insufficiency of the existing tariff laws. Pressure was brought to bear upon the Government to raise the duty on wheat to 3s. per cwt. The result is not quite up to this high level; but the compromise that has been effected between the extreme and the moderate parties fixes the duty henceforward at 2s. 6d. Under these amended laws, Germany has the highest import duties for cereals of any country in Europe. The following is a comparative table of the rates now in force per cwt.:—

	Wheat.	Rye.	Barley.	Oats.
	s. d.	s. d.	s. d.	s. d.
Germany	2 6	..... 2 6	..... 1 1·5	..... 2 0
France	2 0	..... 0 7·3	..... 0 7·3	..... 1 2·6
Spain	1 9	..... 1 3·5	..... 1 3·5	..... 1 3·5
Austria.....	1 6	..... 1 6	..... 0 9	..... 0 9
Italy	1 2·6	..... 1 2·6	..... 0 5·6	..... 0 9·7

HARBOUR WORKS AT BORDEAUX.

Although there has been some improvement shown recently in expediting the publication of British consular reports, a good deal of the information obtainable from these sources is out of date. Mr. W. Ward, our consul at Bordeaux, is, however, alive to the importance of supplying early information, and we quote the following extract from a report made by him: "Although no official notice to such effect has been published here, I am enabled to state, upon the strength of trustworthy information, that the contracts for the execution of the improvements in the basin and quays of Bordeaux will be put up to public competition at Bordeaux, to all probability in March or April next, and that after publication thereof about one month will be allowed to intending contractors for sending in tenders. The works projected consist of about 1600 metres (5250ft.) of stone embankment on the left bank of the river at Bordeaux, and of 500 metres (1640ft.) of iron piles and jetties on the right side of the river, and of various improvements in the existing wet dock basin. These latter will include new iron palisading, hydraulic winches, a second hydraulic machine for opening the dock, strengthening of sifting sluices, new works for emptying locks, a new floating gate, boring of another artesian well, construction of a short aqueduct, and ballasting of quay platforms. Although British firms desirous of competing for the contracts for the various kinds of work required must not be disappointed if they should fail in obtaining the same, in view of the strong feeling at this port against awarding contracts of the nature in question to foreigners, it may, in view of the importance of the works projected at Bordeaux, be well for them to be prepared in due time, and to make themselves acquainted with the precise nature of the work required here."

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

23rd December, 1887.

17659. Cooke, J. ..... Furnaces.
17661. Glover & Whalley..... Stop motions for winding frames.
17663. Matthews & Johnston Governor.
17673. Allen, W. H..... Shaping metals.
17686. Bickerton, H. N..... Gas engines.
17689. Clark & Clark ..... Steam engines.
17697. Hanrez, P..... Steam boilers.
17702. Nordenfelt, T. ..... Turret mountings for guns.

24th December, 1887.

17708. Boulton, I. W..... Traction engines.
17716. Roberts, W..... Boiler furnaces.
17717. Buckland, H. B. ..... Steam boilers.
17718. Bailey, W. H. ..... Wool combing machines.
17721. Smith, R. B. ..... Hydraulic riveting machines.
17738. Weatherhogg, G. W... Petroleum engines.
17739. Mondini, L. ..... Double ash pit for furnaces.
17744. Hogg, T. C. ..... Petroleum engines.
17747. Saunders, S..... Tubular boilers.
17752. Davies, E..... Compound engines.
17758. Longridge, J. A..... Ordnance and cartridges.

27th December, 1887.

17782. Hodgson, G. H. ..... Looms.
17790. Reed, J..... Marine boilers.
17792. Boult, A. J. ..... Breech loading fire arms (*Hampton*).
17795. Proctor & McPherson Spinning machinery.
17798. Lake, H. H. ..... Grinding mills (*Coles*).
17806. Gubbins, R. R..... Rolling mills.
17808. Stratton, E. P. ..... Steam separators.

28th December, 1887.

17822. Nasmith, J. W..... Carding engines.
17823. Carter & Haley..... Apparatus for sawing metals.
17824. Chandler, N. ..... Centrifugal fans.
17828. McLaine, L..... Machinery for spinning flax.
17835. Bridgman & Hodges ... Box nailing machines.
17841. Taverdon & Taverdon Rotary engines.
17843. Galley, J. G. ..... Furnaces.
17847. Newton, P. A. ..... Propelling and steering vessels (*Chesebrough*).
17857. Haddan, R. ..... Machines for cutting bricks and tiles (*Burr & Stipes*).
17858. Loudon, G. S. ..... Utilising waste steam.
17860. Gilmour, J. ..... Fresh water apparatus for steamships.

29th December, 1887.

17861. Hargreaves & Hargreaves ..... Printing.
17870. Orr, R. ..... Steam boilers.
17872. Burgess, W..... Alarm guns.
17874. Armitage & Sons ..... Looms.
17876. Kershaw & Bennett... Type writing machines.
17878. Thompson, W. P..... Apparatus for dyeing textile fabrics (*Hampe*).
17879. Hancock, J., & others... Traversed warp machine.
17887. Negri, C. de..... Knitting machines.
17888. Smith, G. A..... Marine governors.
17891. Jarman, H. ..... Multiple cylinder engines.
17895. Jörg, J..... Spinning machines.
17896. Abel, C. D..... Gas engines (*Gas Motoren-Fabrik Deutz*).
17899. Willcox, B. ..... Furnaces (*Perret*).
17903. Kirkaldy, J..... .. Obtaining fresh water on board ships.

ELECTRICITY.

23rd December, 1887.

17655. Mills, R. H. D..... Incandescent lamps.
17669. Smith & Sinclair ..... Telephonic apparatus.
17682. Cheesman, T. ..... Telephones.
17704. Herts, A. C..... Telephones.

24th December, 1887.

17722. Gisborne, J. S..... Telegraphic apparatus.
17726. Statter, J. C. ..... Electromotors.
17757. McMullin, M..... Incandescent lamps.
17762. Sellner, L. ..... Electric signalling apparatus.

27th December, 1887.

17807. Rawson, F. L. (Woodhouse & Rawson)..... Rheostats (*Wirt*).
17812. Zipernowsky, C..... Alternating electric currents.

28th December, 1887.

17837. Justice, J. M. ..... Generating electricity from heat (*Acheson*).
17840. Barker & Hills ..... Electric indicator.
17846. Anders, G. A., & others Telephonic apparatus.

29th December, 1887.

17863. Haswell, R..... Producing electrical energy.
17902. Pitt, S. ..... Telephone exchanges (*Scribner*).

CHEMISTRY.

23rd December, 1887.

17657. Staveley, W. W..... Alkaline carbonates.
17676. Lawrence, R. S. ..... Carburetters.
17696. Bailey & Greaves ..... Improved saccharum.

24th December, 1887.

17754. Westgarth & Charnock ..... Coating metals with alloys.

27th December, 1887.

17772. Plummer, J..... Hydrochloric acid.
17809. Rigaud, F..... Smelting zinc ores.
17811. Imray, O. ..... Colouring matters (*Farbwerke vormals Meister, Lucius and Brüning*).

29th December, 1887.

17898. Redfern, G. F..... Heat generating apparatus for use as a blow pipe (*Jolicard*).
17905. Gassner, C..... Manufacture of galvanic dry elements.

MISCELLANEOUS.

23rd December, 1887.

17653. Vine, J. W., & others ... Rag tearing machines.
17658. Radcliffe, J. ..... Safety lamps.
17664. Nelson, J..... Economising fuel.
17666. Hartung, H..... Fire bars.
17667. Bevan, J. ..... Apparatus for paring silk or felt hats.
17670. Rowbotham, T..... Machine for ironing hat brims.
17672. Barthel, A. E..... Manufacturing articles from sheet metal lattice work.
17675. Townsend, T. G..... Gates.
17677. Griffiths, W. J..... Twist drills.
17683. Harper, T. ..... Needles.
17687. Maier, S. ..... Binders for letters (*F. Soenneckens Verlag*).
17688. Burns & Dumbell ..... Locks.
17690. Beard, J..... Ironing stoves.
17692. Newton, H. E..... Anchors (*Starr*).
17694. Dehany, G. E. ..... Extinguisher for lamps.
17701. Vero, C..... Manufacture of felt hats.
17705. Snelgrove, W..... Machinery for weighing.

24th December, 1887.

17707. Pike, W. H. ..... Gas stoves.
17710. Maxim, H. S..... Self locking sight for guns.
17712. Sawrey & Colley ..... Separating liquids from solid matters.
17713. Doyle, D. ..... An improved "graph."
17714. Deakin, W. ..... Card shooting machines.
17715. Atkins, F. G..... Funnels.
17720. Holmes, J. H..... Valve gear.
17723. Sewell, S. J..... Type writer.
17724. Fevez, V. P. ..... Velocipedes.
17725. Nicholas & Fanshawe. Shot and shell.
17731. Perry & Perry ..... Laundry trucks.
17736. Horn & Robson ..... Jointing building blocks.
17737. Bosch, J. A. ..... Car coupling.
17741. Wilmott, F. A..... Wire netting machines.
17746. Guérin, J. B..... Apparatus for preserving milk.
17753. Johnson & Wickens .... Tricycles.
17755. Barber & Peach..... Trucks.
17756. Williams & Puplett... Refrigerator.
17760. Clark, A. M..... Compressing air (*Honigmann*).
17761. Jaeggli, J..... Brakes.
17763. Leak, E..... Apparatus for supporting pottery in kilns.
17764. Lockwood, W..... Packing rings of pistons.
17765. Miller, H. P. ..... Heating apparatus.
17766. Ribault, G. E..... Apparatus for coupling rolling stock.
17767. Archer, J. A. ..... Material for roofing.
17768. Smith, W. S..... Apparatus for insulating wire.
17770. Lysaght, J..... Apparatus for coating metal plates.

27th December, 1887.

17773. Bingham, C. H..... Clocks.
17775. Bird, W. H. ..... Locks.
17777. Otley, G. ..... Prevention of fouling of chimneys.
17778. Fuller, S. C. L. ..... Improved shaft fulcrum.
17780. Howes & Howes ..... Driving gear for bicycles.
17783. Loesewitz & Maass..... Lubricators for railway cars.
17786. Brooksbank, R. ..... Washing machines.
17787. Hedderly, C. H., and others..... Oil feeder.
17788. Cockburn, D., & others. Wheelbarrows.
17789. Bell, J. B..... Gas stoves.
17791. Allison, H. J. ..... Cord fastener (*Warner*).
17793. Thompson, W. P..... Apparatus for extracting the juice from cane (*Man*).
17794. Thompson, W. P..... Hinges (*Strachan*).
17796. Roberts, L., & others... Machines for armoring hose.
17797. Roberts, L., & others... Spiral springs.
17799. Hutchinson, H. ..... Generating gas.
17800. Cole & Cole..... Apparatus for branding packing cases.
17802. Samson, A..... An improved hay rack.
17803. Baylis & Howarth..... Railway fish plate.
17804. Wicken, W. B..... Incandescent gas lighting.
17810. Manton & Newton..... Sights for fire arms.
17814. Quarante & d'Escalonne..... Process for preserving wood.

28th December, 1887.

17818. Bradshaw, A. ..... Return steam traps.
17819. Barker, J., & others ... Safety appliances for the doors of hoist wells.
17820. Henderson, J..... Feathering gear of paddle wheel floats.
17825. Wilson, A..... Apparatus for veneering felt hats.
17827. Bradshaw, A. ..... Back pressure valves.
17829. Rogers, C. D..... Method of screw threading the points of wood screws.
17830. Rogers, C. D..... Device for holding and guiding screw blanks.
17831. Rogers, C. D..... Self adjusting die for screw making machines.
17832. Sayer, R. C. ..... Water taps.
17833. Sherwood & Sherwood Paraffin lamps.
17836. Johnson, J. Y..... Permanent way for railways (*Moncharmont*).
17838. Sprange, A. H..... The traverse calculator (*Mountfort & Mountfort*).
17839. Johnson, J. Y..... Improvements in flexible supports carrying buckets (*Damey*).
17844. Scott, J. S..... Solid letterpress printing plate.
17845. Murphy, P. E. ..... Snow destructor.
17848. Keats, C. H..... Machinery for lasting boots and shoes.
17852. Thompson, W. P..... Ventilation (*Oehlmann*).
17853. Upsdale, J. ..... Manufacture of gloves.
17854. Wacks, L..... Trigger action for opening doors.

29th December, 1887.

17864. Fenney, T. F. ..... Pipe joint cutting.
17866. Macandrew, A..... Improvements in lug sails.
17875. Bertram, A..... Preventing overwinding.
17877. Thompson, W. P..... Gas lamps (*Deimel*).
17880. Newlands & Alliott... Separation of solid matter from water.
17881. Andrews, W..... Velocipedes.
17882. Osborne, H..... Means of attaching india-rubber tyres to metal wheels.
17884. Anderson, A. ..... Sewing machine shuttles (*Singer Manufacturing Co.*).
17886. Field, E., & others ..... Lock nuts.
17889. Eli, A. J. ..... Supplying petroleum to wick burners.
17890. Dick, W..... Securing cast metal plate work.
17901. Wenster, C. J..... Apparatus for gilding the backs of books.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

28th December, 1887.

401c. Fryer, R. McC..... Bearings for propeller shafts. (Originally included in No. 401, 1887, takes, under Patents Rule 23, that date.)
834. Larrabee, C. S..... Machinery for polishing the heels of boots.
2243. Singleton, T. ..... Looms.
2354. Boult, A. J..... Apparatus for bleaching wool (*De Pawlowski*).
2755. Boult, A. J..... Apparatus for loading cartridge shells (*Hazard*).
2840. Russell, D..... Furnace bars.
2942. Smith, D. P..... Machines for finishing woven fabrics.
2967. Batley, J. A..... Steam boilers.
2968. Newton, A. V..... Cutters for paring the soles and heels of boots and shoes (*Keats and Keats*).
2970. Stone & Burnett..... Looms.
2978. Stoner, J. B..... Elevating grain.
3010. Earnshaw, E., others... Furnaces.
3011. Wrigley & Patterson.. Carding engines.
3013. Keith, J..... Boilers.
3041. Oliver, M. J..... Harvesting machinery.
3340. Wicksteed, J. H..... Machines for cutting hot blooms, &c.
3900. Simmons, T. J..... Compound steam engines.
16144. Williams, H..... Gas motor engines.
16161. Hampson & Marshall.. Machinery for raising nap upon textile fabrics.
16290. Craven, W. ..... Machine tools for cutting and shaping metals.

31st December, 1887.

17121. Burton, B..... Magazine fire arms.
193. Wallace, J. O..... Apparatus for breaking, scutching, and cleaning flax.
336. Holt, J..... Expansion rollers for levelling yarn on beams.
2227. Shepherd, J. W..... Collapsible ship boats.
2449. Birch, H..... Sewing machines.
2684. Denison & Ward..... Improvements in wheels, pulleys, and bearings.
2744. Shaw & Chittick..... Machinery for punching holes in metal plates.
2747. Gray, J..... Machines for separating fluids.
3112. Brown, A. B..... Hydraulic cranes for ships.
3853. Corden, H..... Boilers.
6955. Butler & Howarth.... Machinery employed in spinning cotton.
11277. Winby & Winby..... Cable tramways.
16295. Richards, N. H..... Brake gear of cable tram cars.
16345. Robertson, J. B..... Sewing machines.
16363. Evans, W. W..... Type writing machines.
16426. Thompson, W. P..... Joint for crossing parts of corrugated metal (*Hodges*).
16492. Lami, J..... Braiding machines.

ELECTRICITY.

28th December, 1887.

17120. Crompton & Swinburne Dynamo machinery.
3998. Chary, F. J..... Electric light.

Digitized by Google

31st December, 1887.

15344. Clark, A. M..... Automatic governor for electric lighting (*Electrotechnische Fabrik Cannstatt*).
16865. Davies & Shearer..... Coupling up batteries.
15099. Foster & Steljes..... Type printing telegraphs.
16406. Delany, P. B..... Telegraphic transmission.
16424. Thompson, W. P..... Telegraphic instruments (*Burke*).

CHEMISTRY.

28th December, 1887.

12295. Atkins, G. J..... Separation of gold.
1132. Windham, F..... Manufacture of gas.
2983. Marshall, G. F..... Carbon for filtering purposes.
2999. Brode, L. A..... Preparing ironstone waste for smelting.

31st December, 1887.

6022. Johnson, J. H..... Explosives (*Engel*).

MISCELLANEOUS.

28th December, 1887.

16979. MacIlwaine, A. W..... Apparatus for extracting oils.
1057. Hunt & Wilson..... Treatment of cotton seed.
1647. Holmes, C., & others ... Bearings for washing machines.
1910. Colby, J..... Railway chairs.
2214. Mackay & Christiansen Refrigerator.
2489. Bown, W..... Improvements in rims of wheels.
2490. Bown, W..... Improvements in the spokes of wheels.
2700. Pipe, H..... Velocipedes.
2911. Morgan, W..... Machines for finishing felt hats.
2912. Barber, J..... Stove grates.
2944. Read, A..... Lids for sheet metal kegs.
2952. Woodward, J..... Lock.
2990. Statter, J. G..... Apparatus for enabling speeds to be ascertained at a distance.
3004. Bradley & Whalley.... Washing machines.
3026. Bowman & Bowman..... Lanterns.
3043. Sutton, J. B..... Elevator buckets.
3067. Fenby, J. B..... Appliances for supplying hydrocarbon oils to burners.
3103. Laws, R..... Washing machines.
3254. Booth, J..... Metal cup with porcelain lining.
8894. Cox & Cox..... Anchors.
11410. Reid, J. C..... Rendering doors draught proof.
11533. Palmer & Stock..... Fastenings for boxes.
11664. Munier & Salvaire..... Process of staining wood.
13313. Boorman, J. A..... Apparatus for ascertaining the angles of bevel and mitre wheels.
13688. Gross, H..... Bricks.
14887. Campbell, D..... Improvements in ships' yards.
15756. Furnival, T., & others.. Machines for cutting cardboard boxes.
16150. Thompson, W. P..... Lamp burners (*Deimel & Von Bühler*).
16181. Norris & Simmons..... Sewing machines.
16201. Lendrum & Mitchell.. Stockinette frames.
16225. Iliffe, G. Y..... Improvements in castors.
16245. Baillie, R..... Corrugated plates.
16246. Brüggemann, F. A..... Vacuum brakes.
16286. Hornsteiner, R..... Apparatus for guiding driving bands.

31st December, 1887.

16940. Fraser, W..... Lubricators.
75. Patterson & Strype... Lamps for burning paraffin.
99. Lamont, S..... Packing for stuffing boxes.
592. Stubbs & Thornton.... Steam traps.
1024. Illidge, A..... Fastenings for doors.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Steam Boilers.—*W. Waller, Hasland, near Chesterfield.*—The inventor proposes to introduce four improvements into the construction of an ordinary steam boiler. In order to secure the freer expansion of parts of the fabric of the boiler without occasioning strain in other parts, he substitutes for the solid screwed stays in the fire box a conical or hollow vessel, which is screwed into the inner wall of the fire box and secured to the outer wall by a screw formed on the stay. He provides for the better circulation of the water by conducting it in pipes externally to the boiler, from the part of the boiler where the sediment has been deposited to the furnace end of the boiler. In order to obtain as much heat as possible from the gases as they pass along the boiler tubes, the inventor places within those tubes other tubes containing part of the water of the boiler. The boiler plates are to be made with alternate projections and recesses, in order to give additional strength to the plates, and to increase the area of the heating surface. There are four claims.—No. 811. January 19th, 1887. 11*d.*

Extraction of Saccharine Matter from the Cane.—*M. A. Perret, Paris.*—The apparatus which is hereby patented is designed for treating sugar cane out of contact with the air, and for kneading, macerating, and pressing the cane by a continuous action. The apparatus is constructed of three principal parts, viz.: the disintegrator which is shown in general view in Fig. 1, and part of it to a larger scale in Fig. 2, a diffusing and pressing apparatus, and a conical pressing apparatus. The cut cane is

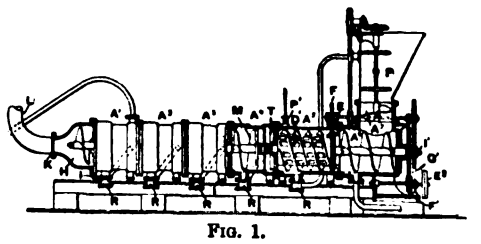

Fig. 1.

delivered from the hopper P into the revolving feeding screw A^7. Whilst it passes through A^6 it is saturated with steam. The screw in A^6 feeds the mass into the disintegrator A^5, which is shown in Fig. 2. A cone B with a helical blade C pushes the charge against the drum B^1, which also has an external blade C^1, and holes on which are placed cutters D^1. The cone and drum rotate in opposite directions. The cane arrives in a disintegrated condition in the annular space E^2, and is pushed out of the annular opening F^2 into the diffusing and pressing compartments A^4, A_2, A_3, A_1. All parts of the machine are supplied with liquid, which is also provided with an escape pipe. After

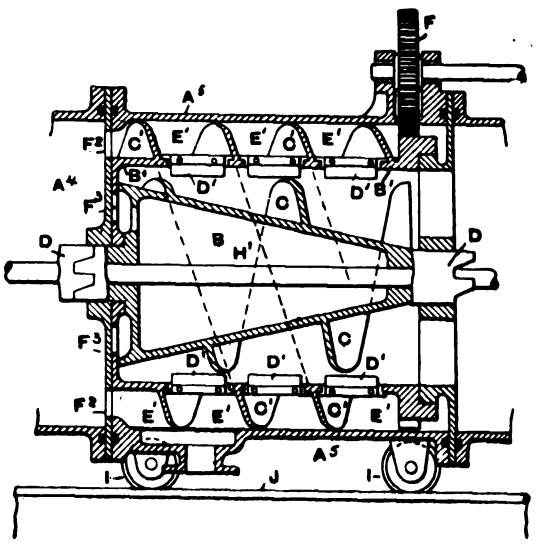

Fig. 2.

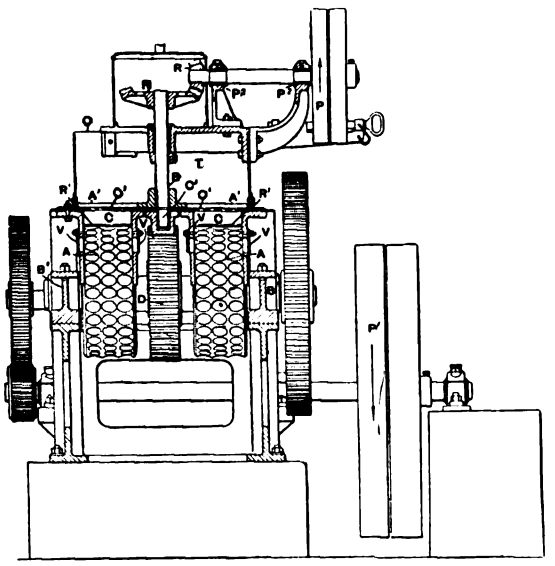
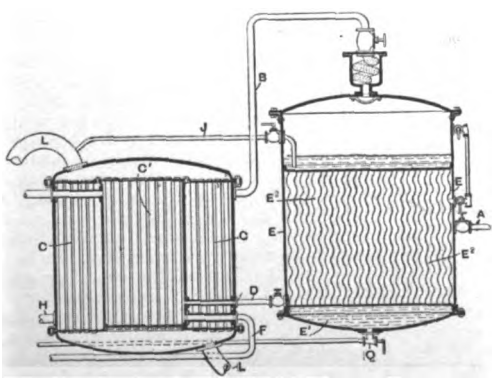
the mass has been treated in this process it is forced by the screw H up the pipe at the end, and into another machine, where it experiences a similar treatment. After the fibrous mass has been thus exhausted of its saccharine matter it passes into a cone. Here it is pushed by blades into a conical press, which is provided with two screw blades, and the fibre is thereby pressed through an opening, while the liquid runs back through a pipe at the bottom of the cone. There are seven claims for the various parts of this apparatus.—No. 1931. February 7th, 1887. 1*s.* 3*d.*



Paper Cutting Machines.—*H. P. Trueman & J. G. New, Birmingham.*—This invention relates to the guillotine paper cutting machine, and has for its object certain improvements and novel arrangements of the various parts. A bracket for carrying the worm and worm wheel is fixed in front of one of the upright members of the frame, instead of at the end of the frame as heretofore; and the space vacated by the worm and wheel is now occupied by the fly wheel and crank. Also the connecting rods from the worm wheel to the knife bar are placed immediately behind the worm wheel and in front of the knife bar. The clamping and releasing of the material operated on is effected by placing a sliding nut on the frame work of the machine; and the said nut is pressed down by a spring, which is compressed by the knife bar on its upward stroke. Means are also supplied for arresting the automatic action, thus converting the machine into an ordinary hand cutter. An improvement in the moving and holding of the fence or gauge is introduced by discarding the usual slot in the table for a guide for the nut, and by carrying the usual screw for operating the gauge completely across the cutting machine from end to end, where it runs in bearings. The nut working on this screw is provided with a vertical extension, which passes through the slot and is fixed to the gauge; and there is also a horizontal prolongation which extends a long distance down the screw shaft, and there embraces the same. By this means is insured a bearing as long as the gauge itself, thus reducing the error caused by the wearing of the parts. There are five claims made, one for each of the improvements described above.—No. 15302. Nov. 24th, 1886. 8*d.*

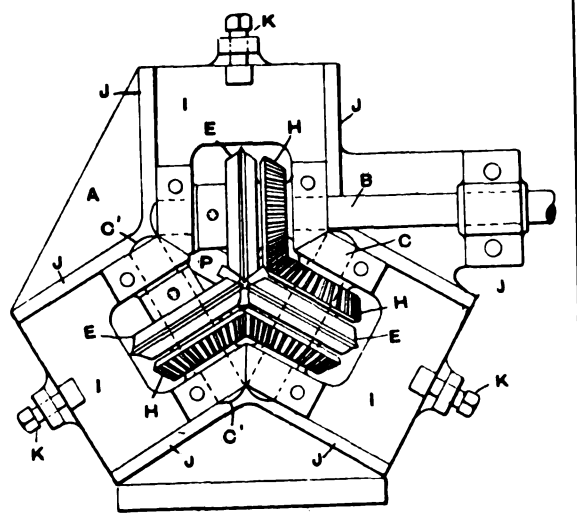
Carding Engines.—*J. Elce & T. S. Whitworth, Manchester.*—To improve the method of adjusting the flats relatively to the main cylinder, the inventors attach to a flange on the engine

Digitized by Google



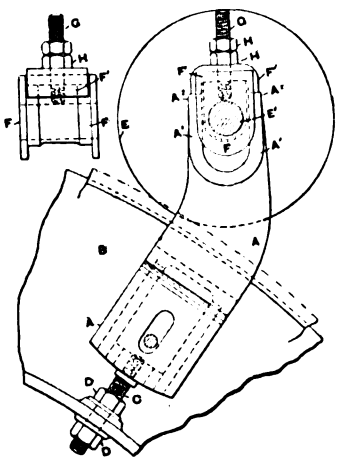
bend a disc or plate provided with slots, one for each flat supporting bracket. The upper end of each bracket is shaped to the segment of a circle concentric with the cylinder. A second disc or plate is mounted on a flange on the face of the first. Each bracket carries a stud or projection which fits into a helical groove on the inner face of the second plate. The flats are adjusted relatively to the cylinder by rotating this plate by means of warm gearing. Both discs are revolved together when it is desired to grind the flats. To allow of adjustment, the bearings of the cylinder are fitted so as to slide vertically in the pedestal. Beneath each bearing is an eccentric shaft or bolt, which is rotated by means of a worm and worm wheel. As the eccentric bolt is turned the bearing is either raised or lowered. The inventors make six claims for the improvements described. —No. 1427. January 29th, 1887. 8*d*.

Apparatus for Moulding Blocks of Artificial Fuel.—*J. Y. Johnson, London.* (*G. Mülheims & R. Zimmermann, Neuf-les-Mines.*)—The object of this apparatus is to mould artificial fuel in blocks of an ovoid shape. There is no necessity for breaking up blocks of this shape before putting them on the fire, and there is little stoking required, because the blocks will of themselves assume a proper position; also the currents of air can easily find access through the intermediate spaces between the blocks. The figure shows an elevation of a press used in this process. The rotary cylinders A fit with similar cylinders, which are placed behind and parallel to them, and are provided with mould forms recessed into them as shown. A hopper T consists



of a box which contains the material to be operated on. A distributing arm A^1 has a horizontal rotary motion given to it by the shaft B, and works along the bottom of the hopper, moving the material through the shoot C, whence it drops H between the two cylinders that carry the moulds, and is compressed into shape. The balls are discharged automatically from the moulding recesses, simply falling out owing to the shallowness of the said recesses. The inventors make three claims: (1) For the apparatus for producing ovoid blocks; (2) for the combination of arm and hopper with the compressing cylinders; (3) for the method of construction of the compressing cylinders.—No. 14531. October 25th, 1887. 8*d*.

Apparatus for Obtaining Fresh Water from the Sea.—*W. F. Pamphlett, Portsea, Hampshire.*—This invention relates to an improved method for obtaining fresh water for drinking purposes, or for feeding the ships' boilers. In the Figure, E shows the evaporator and C the condenser. The evaporator consists of a vessel made of any suitable material according to the pressure of the steam. The corrugated tubes E^2 are of brass or steel, and connect the upper and lower parts of the vessel E. The water to be evaporated is led into E through the pipe J and fills the space E^1 and the tubes. The steam from the boiler enters through A and fills the spaces between the tubes, passing out through the pipe D. The evaporated steam is



conducted to the condenser through the pipe B. The condenser is made in the same way as the evaporator, but consists of two separate concentric chambers C and C^1. The evaporated steam enters C, where it is condensed by circulating cold water, and is afterwards drawn off by the pipes L. The steam from the boiler passing through D into C^1 is also condensed by the cold water, and is drawn off through the pipe F. The sediment and saline matter deposited in E^1 is blown off through the pipe Q. There are four claims.—No. 14228. October 19th, 1887. 8*d*.

Longitudinally Grooved Wire.—*H. H. Lake.* (*P. Clifford and J. Coupal, Quincy, Massachusetts, & J. E. Bertrand, Boston, Massachusetts, U.S.A.*)—This invention has for its object the provision of improved means for longitudinally grooving wire by a rolling process, and also consists in the article produced. The wire is adapted for use in the boot and shoe sole nailing machines as the material for sole fastenings. The figure shows a front elevation of the machine which embodies this invention. J represents the stand or frame, having bearings in which are journalled the shafts B, C, C^1. To these shafts are fixed the grooving rolls E. The bevel wheels H are fixed to the shafts

and cause the rolls to act simultaneously on the wire. The shaft B is driven by any suitable motor, and motion is communicated from it to the shafts C, C^1, the series of rolls being thus positively rotated and caused to simultaneously feed and groove the wire. Behind are placed some guides which lead the wire into a suitable position for entering the space between the three rolls. The bearings of the shafts are made adjustable by means of the slides I and the screws K. The wire thus has three longitudinal ribs impressed upon it, and is also compacted by the pressure to which it is subjected. There are five claims for the various combinations.—No. 13837. October 12th, 1887. 8*d*.

Carding Engines.—*W. Taylor, Oldham.*—This invention relates to the brackets for carrying the grinding roller and stripping brush of a carding machine. The improvement consists in combining the two separate adjustments for these parts. The figure shows a side elevation of part of the engine bend, with one of the brackets and the stripping brush in position thereon. The bracket A is supported and free to slide as usual on the engine bend B, and is furnished with an adjusting screw C and lock nuts D, by which it is adjusted and secured in position. The circle E represents the outline of the stripping brush, and E^1 is the spindle supported in the bearing F, which is fitted into slide ways A^1. A cap F^1 is connected to the step F by a screw G, which passes through the cap and screws into the step. The step F enters the neck of the bracket A, while the cap F^1 rests on

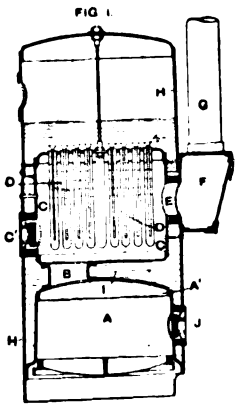
the upper surface A^2 of the slide ways A^1; so that by operating the nuts H the step carrying the brush may be lowered or raised to or from the wire of the cylinder. The grinding roller is supported by a plain step, which rests in the bottom of the neck A^1; so that the adjustment of the bracket with the grinding roller is effected directly by the screw C. The object of this arrangement is that, when the stripping brush is required, the grinding roller can be removed and the brush substituted without interfering with the adjustment of the bracket. There are two claims: (1) For the combination of parts for the separate adjustments mounted on one bracket; (2) for the general arrangement of parts.—No. 14406. October 24th, 1887. 6*d*.

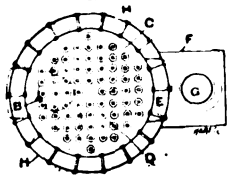
Forging or Shaping Machine.—*T. Allen, Reading, Berkshire.* —The improved machine is adapted to form irregularly shaped articles that are round in transverse section. Upon a suitable bed plate are two bearings carrying a hollow spindle, through which is passed a second solid one. The two spindles are caused to rotate in opposite directions by means of a bevel wheel being attached to one end of each shaft, the driving bevel pinion being inserted between and gearing with them both. Attached to the free end of the hollow shaft is a hollow chuck, inside which a wheel is mounted on the solid spindle. The periphery of the wheel and the inner surface of the hollow chuck carry the dies for forming and shaping the metal. Two claims are made for the forging or shaping machine described.—No. 298. January 8th, 1887. 8*d*.

Steam Boilers.—*O. D. Orvis, London.*—In a boiler fitted with these improvements series of tubes are arranged in the flues in the boiler setting for the purposes of superheating the steam and insuring a thorough circulation of the water. At the point where the blow off cock is usually situated the boiler is connected to a box or header, which is connected by a series of tubes to a drum extending across the flue. The drum is at a slightly lower level than the box or header, and the feed water si introduced into it instead of direct into the boiler. Another series of tubes extend from the drum to the back of the boiler, and are connected to the steam space. In the side flues in the boiler setting are other series of pipes connected at one end to the drum under the boiler and at the other to the steam space. The drum is provided with a blow off cock to discharge any mud or sediment. All the tubes are provided with plugs at the end, which may be removed for cleaning purposes. Three claims are made for the arrangement of tubes as described.—No. 14703. October 28th, 1887. 8*d*.

Steam Generators.—*W. Land, Grantham.*—These improvements relate to vertical steam boilers, and their objects are to simplify the construction and to increase the efficiency and economy of working. Referring to the drawings, Fig. 1 is a central vertical section, and Fig. 2 is a horizontal section through the fire tubes. A is the fire box furnished with a slightly curved top A^1, from which a short tube B leads to a combustion and tube chamber C, the products of combustion passing among the tubes D and escaping through a passage E to the smoke box F and shaft G. There is a water space I between the

FIG. 1.





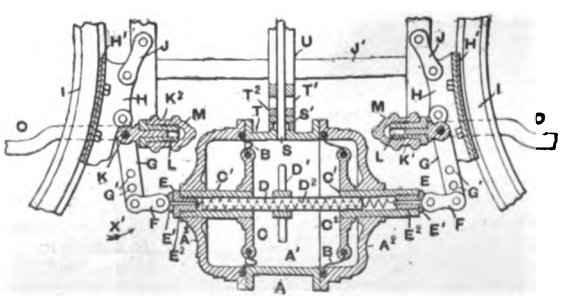


FIG. 2.

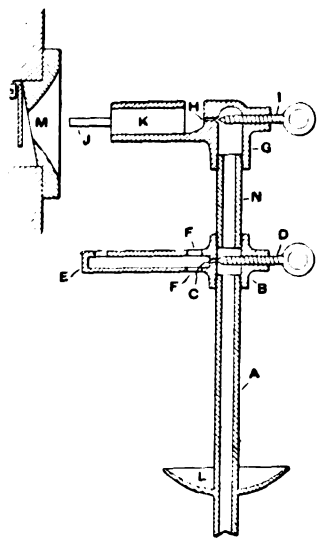
bottom of the combustion chamber C and the top of the fire box. The tubes D are closed at one end. They are fixed vertically in the crown of the combustion chamber and extend to within a short distance of the bottom. The boiler is preferably domed or egg-ended, and is stayed either to the sides of the shell H or to the top of the combustion chamber C. J is the furnace door, and C^1 is a door for cleaning out the combustion chamber. Two claims are made for the improved construction and combination of parts of a boiler.—No. 994. January 21st, 1887. 8*d*.

Vacuum Brakes.—*L. P. Lawrence, Passaic, New Jersey, U.S.A.* —The object of this invention is to arrange the parts of a brake so that they may easily "give" according to the movements of a car or locomotive to which the appliance is attached. A brake saddle is placed on each side of each wheel, and on all the four wheels of a double driving locomotive. The figure shows a longitudinal sectional view of the actuating cylinder, and the links and rods operating on the brake shoes. The tube U communicates with an ordinary air ejector at one end, and at the other with the cylinder A through the opening S. The cylinder



A consists of three parts A^1 A^2 A^3. The pistons C C^2 are fixed to the hollow piston rods C^1, which pass out through the ends of the cylinder and slide on the guiding tube D. This guiding tube is held in position by a cross piece D^1, and through it passes a spiral spring D^2. An annular ring of rubber B is clamped to the outer edge of each of the pistons, and also to the inner wall of the cylinder. The links and levers connecting the piston rods with the brake saddles H on the inner side of the wheels are seen clearly on the diagram. The tubular screw L is screwed into a threaded aperture of a box M, and the fork K, pivoted to the lever G, is formed on the end of a pin K^1, which passes into the bore of the tubular piece L. At the rear of the box M is a mechanism not shown in the

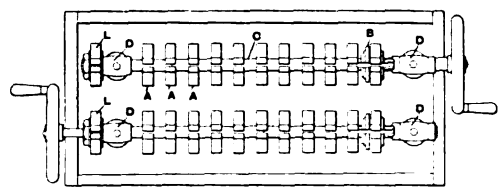
Digitized by Google

diagram. A recess is formed in M, through which passes the threaded end of the connecting rod O. This rod O actuates similar mechanism at the outer side of the wheel, and presses the brake block on the wheel simultaneously with the parts which are shown. When the brakes are not in action, the pistons are held in the position C^2 by the spring D^2. Directly the vacuum is formed by the air ejector the pistons assume the position indicated by C; the links move in the direction of the arrow, and press blocks against the wheels. The joints at E and M allow for the adjustment of the various parts, and prevent any straining whilst the locomotive is in action. The inventor makes sixteen claims, for a brake saddle on each side of each wheel, levers for operating the saddles, a cylinder, piston, and piston rods for operating the levers, as described, and also for the various combinations of the parts.—No. 14155. October 18th, 1887. 8*d*.

Hydrocarbon Engines.—*W. D. Priestman & S. Priestman, Hull.*—This invention refers to an improvement in the system of working an engine which was described in Patent No. 1394 of 1886. Instead of mixing the hydrocarburetted air with the additional quantity of air previous to admission to the motor cylinder, these charges are to be conveyed separately to the cylinder. The inventors make four claims for the improvements.—No. 1454. January 9th, 1887. 6*d*.

Hydrocarbon Engines.—*C. E. Hearson, London.*—This invention relates to certain improvements in the arrangements for utilising the vapour of liquid hydrocarbons for actuating gas engines. The objects of the improvements are chiefly to vaporise the liquid by means of the waste heat from the engine, to cause the vapour to pass into the cylinder by the action of the engine alone, and to fire the explosive mixture by means of the flame of a vapour burner. The vaporisation of the liquid is effected by leading into the reservoir of liquid a pipe through which passes steam coming from the jacket of the cylinder, or from the exhaust pipe. In order to fire the explosive mixture, some of the liquid hydrocarbon is delivered under pressure into

an apparatus, a vertical section of which is shown in the accompanying figure. The liquid is supplied under pressure through a tube fixed to the lower end of the chamber A, and is evaporated by the burning of some hydrocarbon placed in the cup L. The vapour passes through the outlets C H, the sizes of which are regulated by the needle valves D I. Air enters through the holes F in the lower burner, and the mixture of air and vapour burns at E and at the end of K. The two burners E and K are so placed that the flame at K shall be opposite the firing port M of the engine, and that when the explosion extinguishes it, the flame issuing from E shall re-light it. The inventor makes five claims.—No. 15955. December 6th, 1886. 8*d*.



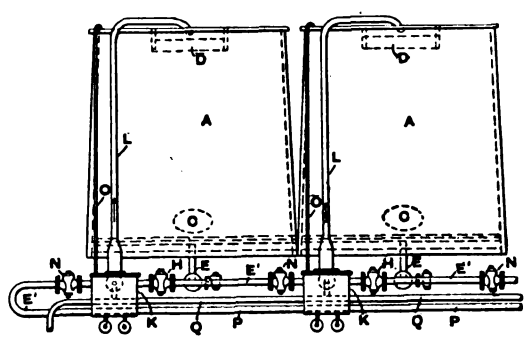
ELECTRICITY.

Dynamos.—*R. C. Jackson, London.*—The inventor proposes to substitute an aluminium and iron alloy for the iron hitherto used in the construction of electro magnets and dynamos. A suitable proportion for the alloy is one part of aluminium to ninety-nine of iron. The advantage of this alteration is an increased electrical effect, as the alloy is very uniform, and has a higher point of saturation or magnetic capacity than the best iron. An incidental advantage is that this alloy is readily cast into clean sharp castings. There is one claim for this improvement.—No. 1390. January 28th, 1887. 4*d*.

Dynamos.—*D. Halpin & I. A. Timmis, London.*—In order to obviate the frictional grooving of the contact surfaces of the brushes and commutator, the inventors propose to impart to the commutator brushes a slight lateral to and fro motion in the direction of the axis of the commutator. A uniform frictional action over the whole surface of contact is thus insured. This motion may be obtained by fixing to the commutator shaft a worm wheel gearing with a worm whose spindle has crank pins on its ends connected by links to the brush holders. The supports of these holders are arranged so as to rock a slide laterally to a small extent. There is one claim for this improvement.—No. 1331. January 27th, 1887. 8*d*.

Underground Telegraph Wires.—*T. O. Callender, London.*—The object of this invention is to reduce the inductive capacity of any underground conductor in an economical manner. The proposed method of laying and insulating the wires is carried into effect in the following way: Cases or troughs of a rectangular shape are made of bitumen concrete, and formed in the required lengths. These lengths are jointed together *in situ*, so as to form a continuous receptacle for the conductors. The wires are cased with the bituminous material described in Callender's patent No. 4409 of 1881, and are protected as usual by tape braiding. They are then laid in the trough, and spaced apart by bridges. Afterwards the vacant spaces are filled up with molten bitumen. The inventor makes one claim for the method above described.—No. 1499. January 31st, 1887. 6*d*.

Distribution of Currents.—*R. E. B. Crompton & J. H. F. Soll, Chelmsford.*—This invention relates more particularly to multiple or regulating switches or commutating apparatus, such as are used for switching the current on to a series of terminal blocks in order. The contact blocks are to be placed in line, and to be made in ring form, and the connection to these rings is made by forcing through them in turn an elastic copper disc. The disc is mounted on a spindle whose axis coincides with that of the disc. The annexed figure represents a plan of one form



of this apparatus. A A A are the ring-shaped contact blocks and B is the elastic disc, which is forced through them by means of the screwed spindle C. The contact rings A are split at the upper side so as to insure a good contact on to the circular disc. In order to convey the current to or from the screwed spindles, a circular revolving contact is preferably employed, and is placed at L as shown in the diagram. The inventors claim: (1) The arrangement of forcing circular discs through ring-shaped contacts; (2) the split ring-formed contacts; (3) the use of rows of contact rings side by side with operating mechanism to regulate an accumulator or other electric batteries; (4) the combination of parts for operating several circuits of different e.m.f.—No. 275. January 7th, 1887. 8*d*.

CHEMISTRY.

Colouring Matters.—*O. Imray, London.* (*Farbwerke vormals Lucius & Brünig, Höchst-am-Main.*)—This invention consists in the manufacture of blue or violet colouring matters by the action of paranitroso-derivatives of secondary amines on phenols and oxycarbonic acids. One of the examples mentioned in the specification runs as follows: To five parts of chlorohydrate of paranitrosodiphenylamine and eight parts of gallic acid are added fifty parts of acetic acid. This mixture is heated on the water bath until it assumes a blue colour, the product is then poured into cold water and the blue colouring matter is precipitated. The claim made by the inventor is substantially embodied in the first sentence of this abstract.—No. 737. January 17th, 1887. 6*d*.

Saccharification of Starchy Materials.—*V. C. A. M. Bondonneau, Paris, and A. J. M. G. Fosèt, Chalon-sur-Saône.*—This invention relates to a process and apparatus whereby acid saccharification can be effected in such a manner as to convert all the starchy ingredients and produce a pulp equivalent to that which is obtained by the malt process. Each diffuser-saccharifier consists of a vessel A of wood, copper, or enamelled iron, provided with a double bottom B of perforated wood or metal covered with wire gauze. C is a man hole for emptying the pulp, and D is a box for breaking the flow of liquid. The heater elevator consists of a cylinder K, containing

a conical bell within which is a steam coil for heating the liquid. The process operates in the following manner: The saccharifier A is charged with the vegetable matter and water acidulated with any suitable acid, and is placed in communication with the heated elevator K by means of the pipe E and the cock H. Steam is introduced into the steam coil, so that the liquid flowing round the same is heated to boiling point, and by its expansion is forced up the pipe L into the box D. Thus a circulation of liquid is set up, and the boiling liquid is made to flow slowly through the whole mass of matter in A, heating it and converting it into saccharine matter. The syrup is then allowed to run off through the cock F, and a corresponding amount of water is allowed to enter K through another cock. The process thus continues until the whole of the saccharine matter is drawn off. There are two claims for the process above described.—No. 986. January 21st, 1887. 8*d*.

Manufacture of Aluminium Alloys.—*E. Cleaver, Stockwell, Surrey.*—This operation consists of extracting aluminium from its oxide, and alloying it with iron. Alumina is dissolved in sulphuric acid, and the sulphate of alumina so obtained is absorbed into finely powdered carbon. The salt is then reduced by heating the mixture out of contact with air, and the material thus obtained is mixed with cast iron filings and raised to a temperature sufficient to melt the metal. An alloy of iron and aluminium is the result. Other salts, such as the ferrocyanide, may be used instead of the sulphate. There are four claims for the branches of this process.—No. 1276. January 26th, 1887. 6*d*.

Peroxide of Lead.—*D. G. Fitz-Gerald, London.*—The inventor prepares peroxide of lead for use in voltaic batteries by mixing monoxide of lead with an insoluble salt of lead, such as the sulphate, together with a certain quantity of water. This mass is then placed in moulds of the required forms, where it gradually sets into a porous and coherent shape. An addition to the above mixture of a small proportion of peroxide of lead promotes its setting and augments its conductivity. Three claims are made.—No. 16608. December 17th, 1886. 6*d*.

MISCELLANEOUS.

Illuminated Fountains.—*C. J. Galloway & J. H. Beckwith, Manchester.*—This invention relates to certain arrangements by means of which the control of the fountain jets and of the coloured slides may be in the hands of one or two operators, who occupy a commanding position. The main supply pipe is provided with as many valves and branch pipes as there are minor fountain jets. Each valve is worked by a suitable lever connected to it by a set of rods or counterweighted chains, and all the levers are arranged in a row so that they shall be under the control of one man. In a similar way another set of levers operate on the coloured slides. When the extent over which the slides are disposed is considerable, each of the rods or

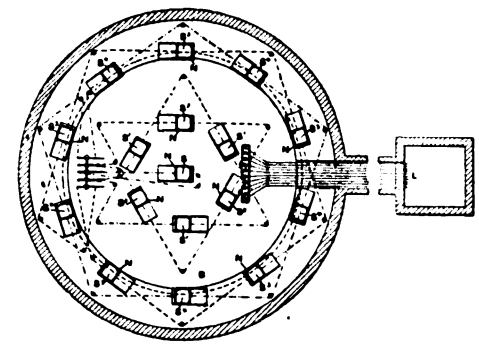


Fig. 1.

chains is preferably attached to the piston of a hydraulic or pneumatic cylinder, and then the attendant, by opening a cock or valve, can transmit pressure to work the set of slides. In the accompanying diagrams, which represent a plan and vertical section, B is the basin of the fountain, and underneath are arranged the main water pipe M and the branch pipes. The valves V of the branch pipes arranged over the main

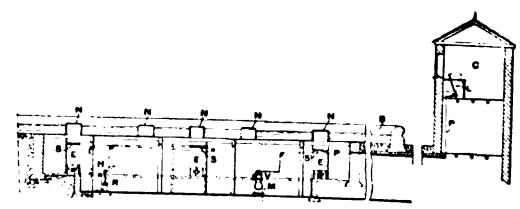

Fig. 2.

pipe, and the levers connected with the valves, are operated by chains and levers L in the cabin. Under each of the glazed hatchways N are placed a series of electric lights E. The sliding screens S, glazed with coloured glass, are fitted underneath each of the hatchways, and are connected by means of cords and pulleys with the levers H. The screens are preferably grouped in sets, so that one of the levers H works all of one set. Thus, as indicated in the plan, the middle lever H works the central screen S, the levers H^1 and H^2 respectively the three screens S^1, and the three screens S^2, and so on. Each screen may have many successive coloured glasses. The levers H may be worked by hand, or by pneumatic or hydraulic power. Claim: The arrangement under the basin of a set of valves and a set of coloured screens to be worked by levers in a cabin commanding a view of the fountain.—No. 1460. January 29th, 1887. 8*d*.

Underground Conduits.—*A. J. Boult, London.* (*E. E. Ries, Baltimore, U.S.A.*)—This invention relates to underground conduits for electrical conductors for railway or telephonic, &c., purposes, for cables for a cable railway, and for pneumatic or hydraulic tubes. A suitable trench is excavated along the line of way, and suitable brackets or ties are placed across it and supported on a foundation of asphaltum or similar material. The brackets consist of a perforated iron plate, provided with flanges, on which rest the track rails, and the rails forming the slot for the cable gripper or current collector. The perforations in the ties receive tubes for containing the telephonic, &c., conductors, or for conveying air and water. Suitable recesses are cut in the flanges of the ties to form a firm seat for the slot rails. Along the edges of the slot in the brackets are projecting lips or flanges which deflect any water or foreign matter away from the conductors. Twenty-three claims are made.—No. 12752. September 20th, 1887. 8*d*.

Obtaining Fresh Water for Ships' Use.—*Hamilton Dansey, London.* (*L. C. Auldjo, Sydney, N.S.W.*)—This invention is an apparatus for obtaining fresh water for ships' use, in which the waste gases escaping from the boiler furnace are utilised to effect the evaporation of sea or other water while in a partial vacuum. A vertical tube is fitted in the smoke box, uptake, or funnel of the ship's boiler. Its lower end is led into a tank open to the atmosphere, partially filled with the water to be evaporated. The upper end is connected with a pipe which is in

Digitized by Google

communication with a surface condenser. When the necessary cocks of the tubes have been opened, the water in the tank will rise by reason of the vacuum of the condenser, and will become heated and evaporated by the heat from the waste gases in the funnel or uptake. Being in a partial vacuum, evaporation takes place at a low temperature and rapid rate. The steam thus generated passes into the condenser and is condensed. The height of the vertical tube is required to be about forty feet. The inventor makes two claims, one for the principle involved and one for the mechanism employed.—No. 1089. January 24th, 1887. 8*d*.

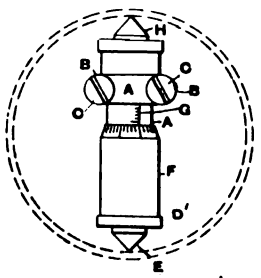
Harvesters.—*A. J. Boult, London.* (*Milwaukee Harvester Company.*)—This invention relates to a grain saving apparatus which is to be affixed to the harvester, in order to catch the grain which is thrashed out in the reaping and binding process. An inclined deck and a rearwardly extending receptacle at the lower edge of the deck are arranged in combination with the frame of the harvester. The deck is corrugated or ribbed, and provided with fingers at its lower edge in order to guide the grain into the receptacle, whilst the bundles are delivered from the deck. There are four claims made.—No. 14853. November 1st, 1887. 6*d*.

Weaving Figured Fabrics. — *C. Brazil & J. E. Johnson Ferguson, Bolton.*—This invention consists of the production of a new toilet quilt or cover, having a weft twill or satin raised figure upon a seed ground. The cloth is woven with three ends or warp threads to every dent of the reed. The weft is thrown in two picks of coarse weft and two picks of fine weft alternately, and the whole pattern of ground and figure is completed in eight picks. A weaver's diagram is included in the specification to illustrate this arrangement. There are two claims, one for the article produced, and one for the method of its production.—No. 7689. May 27th, 1887. 8*d*.

Electric Marine Governor.—*R. B. Maddison, Sunderland.*—This apparatus is designed to control and avoid the racing of marine engines in rough and stormy weather. A cylinder is fixed horizontally to the stern post of the vessel, just below the water line, and is open at the fore end, and has a perforated cover at the after end. A piston is fitted at the front end of the cylinder, and a spring is placed between the piston and the perforated cover. Directly the water declines from light ship water line there is a cessation of the pressure against the fore side of the piston. The spiral spring being thus released, a rod is driven forward and presses an electric bracket, which is connected with a battery. On contact being made a slide valve admits steam into a small cylinder, by which means the throttle valve is closed. The reverse process takes place when the pressure of the water again acts on the piston. The inventor makes two claims.—No. 6584. May 5th, 1887. 8*d*.

Improved Micrometer Gauge.—*D. G. Brown & W. Lancaster, Philadelphia, U.S.A.*—The object of this invention is to provide a device for measuring the inside diameters of pipes or cylinders with increased accuracy. The arrangement of parts will be seen in the annexed diagrams. Fig. 1 represents an elevation of the gauge, and Fig. 2 an elevation of the threaded finger piece. A is a slotted tube having ears B B, by which the sections made by the slot may be drawn together by screws C C to take up wear. The tube is threaded on the inside to receive the finger piece D, which carries a milled flange D¹ and a pointed end E. Upon the finger piece D is screwed a collar F, a graduated flange

Fig. 1.



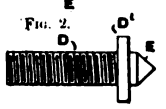


Fig. 2.

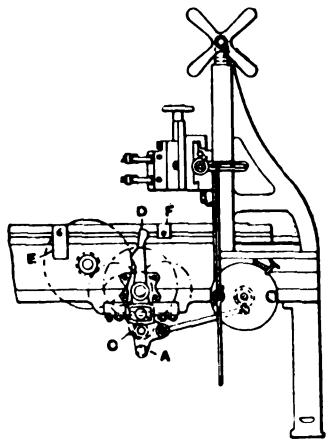
of which is adapted to overlap and inclose a portion of the tube A, which portion has an indicating mark G placed longitudinally thereon. The opposite end of A is provided with a movable pointed tip H; and the distance from H to E will measure the internal diameter. The screws of the finger piece and tube are provided with forty threads to an inch, while the flange F of the finger piece is marked off into twenty-five equal parts. It is thus evident that measurements of internal diameters can be made to the thousandth of an inch. The inventor makes five claims for the various combinations of parts.—No. 13703. October 10th, 1887. 6*d*.

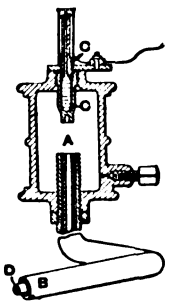
Beaters of Thrashing Machines.—*J. Marshall, Gainsborough.*—According to this invention, the drum ends and foundation rings of the beaters are made with a number of projections round their peripheries. These projections are formed so as to form a seating for the beater beds; they have a flattened higher part which descends in a curve and terminates in a step at the part nearest to the centre of the drum. The beater beds are of iron or steel, and are formed correspondingly with the projections aforesaid.—No. 1248. January 26th, 1887. 6*d*.



Lace Machines.—*A. M. Clark, London.* (*E. Darchicourt, St. Pierre les Calais.*)—The inventor substitutes lever guides through which the threads are led for the "stump bars" of bobbin net machines, and for the "fine bars" through which the warp threads are passed in Lever's lace machines. They also replace the pickers and Jacquard placed behind and above some machines. The guide eyes of the levers may be twisted or alternately flat and cranked. Three claims are made for the improvements described.—No. 1625. February 1st, 1887. 8*d*.

Waterproofing Leather.—*A. Smetham, Liverpool.*—According to this invention, the tanned butts are passed through molten paraffin wax or some similar substance, and then through some solvent, such as petroleum, for the purpose of removing the surplus wax. Two claims are made for the process described.—No. 1009. January 22nd, 1887. 4*d*.

Drums for Paper Making Machines.—*G. Bentley & J. B. Jackson, Bury.*—The flanges or projections on the inside of the cylinder and on the end disc are formed so as to abut firmly against each other, and thus prevent contortion of the drum or cylinder when the fastenings are screwed up. The joint may also be cemented. The inventors make one claim for the improvements described.—No. 2133. February 10th, 1887. 8*d*.



GERMAN PATENT ABSTRACTS.

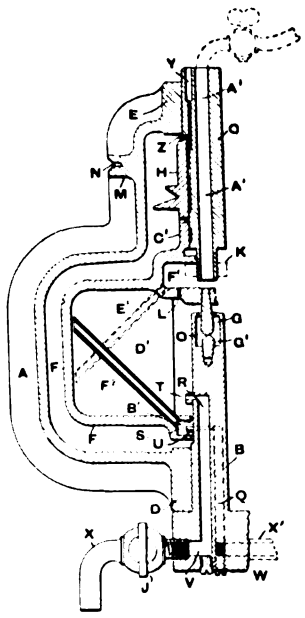
Planing Machines.—*O. Müller, Neuschonfeld, near Leipzic.*—This invention relates to an automatic link motion for planing machines. The link motion is produced by a movable toothed

wheel work C, geared into a suitable combination of toothed wheels. C is attached to a lever A, which is actuated at D by the catches E and F.—No. 41280. March 9th, 1887.

Safety Device for Boilers.—*August Shütte, Oderberg.*—This apparatus consists of a vessel A which is connected to the boiler by two tubes B and D reaching to different levels in the boiler. A thermometer C is fixed in the top of the vessel. As

long as both tubes dip in the water a circulation of water through B and D takes place; but as soon as the water level sinks below the end of the short tube B, steam enters A and reaches C. The quicksilver in C rises, thereby establishing an electric circuit in an alarum apparatus.—No. 41364. March 4th, 1887.

UNITED STATES PATENT ABSTRACTS.



Registering and Recording Scale Beam.—*E. G. Fisher, Minneapolis, Minnesota.*—The travelling weight of a scale beam carries an indicating and recording mechanism, which consists of a train of wheels and a dial. One of the wheels gears with a rack on the upper edge of the beam, and thus the travel of weight is indicated by a finger on the dial. A graduated card can be fixed on the dial plate, and the indicating finger is provided with points which are made to puncture the card and record the weight. The inventor makes twelve claims for the several combinations.—No. 371831, dated 18th October, 1887.

Knife Blades.—*G. Havell, Newark, New Jersey.*—The object of this invention is to provide a sheet metal knife blade with a strong tang, and with a solid bolster fitted tightly upon the tang and shank of the blade. The tang is formed in one piece with the blade, and is made of a prismatic shape by compressing its edges. The bolster has a notch in it so as to fit the butt of the blade, and a central aperture to admit the tang; and the sides of the bolster are compressed with a die in order to close the central aperture against the butt of the blade. There are five claims.—No. 373527, dated 22nd November, 1887.

Gaseous Fuel.—*J. W. Mitchell, Bayonne, New Jersey.*—This invention consists of a process and apparatus for the production and combustion of gaseous fuel. Superheated steam and liquid hydrocarbon are injected together through the wall of a closed firebox or combustion chamber into a retort, where by the decomposition of the steam and the oil gas is generated. This gas is fed with a stream of heated air to support its combustion. The process is as follows: The water in the steam boiler is heated in the first place by the combustion of the oil. When the heat of the water is increased so that it boils, the steam which is given off passes through a superheating coil. On this taking place, the oil and steam are injected into the retort, where the gaseous product is ignited, and supplies further heat to the boiler. The furnace is thus supplied with gaseous fuel generated within itself. There are four claims for these combinations of parts.—No. 373468, dated 22nd November, 1887.

Seam for Wire Cloth.—*J. J. Sellers, Philadelphia.*—In securing the edges of wire cloth, a whipping thread is to be passed alternately round the first transverse wire and another transverse wire, and it is so arranged that this thread shall only pass over one side of the transverse wires. In uniting the edges of two pieces of cloth, the adjacent loops formed by the whipping threads are united with a connecting wire. With this construction it will be seen that the two pieces of cloth are joined in such a manner that there are no projections formed by the whipping wires on one side of the cloth, and that the edges are prevented from being bent or outwardly projected to form a rough or uneven surface. As the whipping wires are not passed successively round any of the transverse wires except the first, a tight and smooth seam may be obtained free from any warping or distorting of the cloth. There are three claims.—No. 372335, dated 1st November, 1887.

Liquid Separator.—*C. A. Backstrom, Trenton, New Jersey.*—This is an apparatus for centrifugally separating such liquids as milk. The machine is provided with a yoke and ring, which constitute a concentric ring or compass support, whereby the whole apparatus will naturally assume a position agreeing with the centre of gravity of the entire structure. The annexed figure shows a section of the frame A, and the bowl F, where the separation takes place. The bowl is supported by the

projections G G¹, and bears on the non-rotating shaft C. The milk flows through the supply pipe A¹ into the annular vessel F¹, then through the pipe E¹ into the interior of the bowl F. The blades inside the bowl are all perforated, except D¹, which is shown in the drawing. During the revolution the cream collects in a ring nearer the centre of support, and passes through R, V, and X, while the milk escapes through F², S, Q, and X¹. By manipulating the cock J, and a similar cock attached to the passage X¹, the inventor can regulate the quality of the resulting liquids which pass off through the two pipes, and thus control the quantity of cream which is taken out of the milk. There are seven claims.—No. 368047, dated 9th August, 1887.

Shuttle Motion for Looms.—*F. W. Wright, Rochester, N.Y.*—The object of this invention is to produce an efficient locking mechanism, whereby the shuttle may be automatically attached to and detached from the carriers. The shuttle is provided with a laterally movable locking lever, and the carriers have laterally movable catches adapted to engage the lever. Springs and stops are arranged on the carriers, so that the catches are held obliquely, in order to shift the lever by contact with its advancing end. There are three claims for these combinations.—No. 373423, dated 15th November, 1887.

Elevated Railways.—*D. D. Read, Boston.*—The inventor designed this arrangement of cars and supports with a view to their occupying as little air-space and foundation ground as possible. The road is constructed on the trussed suspension plan; and a single line of columns is used for a double track road, the trusses being supported on either side of the columns. The cars have centrally placed wheels at their base that sustain the weight, and similarly placed wheels above the car body are used to retain the car in an upright position, as the lower support has no appreciable width to afford the requisite stability. Five claims are made.—No. 373605, dated 22nd November, 1887.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

INDUSTRIES AND COMMERCE DURING 1887.

(Concluded from page 2.)

RAILWAY PROGRESS AND WORKING.

The general tendency of railway property in the United Kingdom during the last year or two has not been satisfactory. The profits realised on the capital invested have been decreasing instead of advancing. This is not due so much to a reduction of business as to an increase of working expenses, and a reduced range of rates and fares. The net receipts on the railways of the United Kingdom as a whole amounted in 1886 to quite £600,000 less than in 1883, although in the interval there had been 44 millions more invested in our railway system, and about 430 more miles of railway opened. The average rate of profit was highest within recent years in 1882, when it was 4·38 per cent., and again in 1880, when it was 4·38 per cent. on the total paid up capital. In 1886 the average had fallen to 3·99 per cent., and there is reason to believe that for 1887 it will not be higher than this figure, if it does not fall below it.

The reduced volume of business done by our railways may be taken as an accurate reflex of the extent of the depression that has occurred in our leading, and especially in our heavy, industries. For a number of years the progress of our goods and mineral traffic was remarkable. This movement proceeded until 1883, when it culminated in a total tonnage of over 266 millions of tons, of which 189½ millions were mineral, and 76½ millions were general goods traffic. Since then there has been a decrease of traffic and of receipts. The mineral traffic fell from a total of 189½ millions of tons in 1883, to 183½ millions of tons in 1884, and although there was a slight recovery in 1885, when the traffic amounted to about 183¾ millions of tons, this increase was not sufficient to compensate for the reduction of general merchandise traffic by nearly two millions of tons, which took place in the same interval. In 1886, the total goods and mineral traffic carried on our railways was 12 millions of tons less than in 1883. Hence we find that, as between 1882 and 1886, the receipts from general merchandise traffic diminished by over £800,000, while the receipts from mineral traffic were reduced by nearly £600,000. If this had happened coincidently with the maintenance of the same mileage and capital, it would have been bad enough; but as it was, it fell in with a large increase of both, and a consequently large reduction in the average earning power of the system, whether measured by the mileage operated or by the capital expended.

The diminution of goods and mineral traffic receipts has some set-off, however, in the increase of passenger traffic. The number of passengers carried on the railways of the United Kingdom advanced from 654¾ millions in 1882 to 725½ millions in 1886, and the receipts therefrom rose from about 25¼ millions to 26 millions sterling. It is extremely doubtful whether any conclusion favourable to trade can be drawn from this undoubtedly large increase of passenger traffic in the interval. About 20 millions of the increase occurred on the two principal metropolitan railways, and in their case it was largely stimulated by the exhibitions at South Kensington.

The rolling stock employed on the railways of the United Kingdom has been considerably augmented, while the traffic has thus remained all but stationary, taking one class with another, and while the gross and net receipts have been diminishing. In 1882 the total number of locomotives employed was 14,128; in 1886 it was 15,400. The number of goods waggons rose from 406,795 to 468,537. The number of passenger vehicles advanced from 31,250 to 34,216. The total number of vehicles and waggons of all kinds rose from 462,061 to 528,090—an increase of 66,029, or 14 per cent. This increase of rolling stock may not, however, represent any real increase of facilities to traders, or of the rolling stock actually available, so far as waggons are concerned, since some of the leading railway companies have recently been buying up private traders' waggons, and in such cases it is simply a transfer of the same stock from the hands of private owners, as to whose business there were no figures available, to those of the railway companies, whose affairs are made public by Act of Parliament.

In the present and recent circumstances of the railway interest, it is hardly probable that concessions of a very substantial character can be expected by traders. The ensuing session of Parliament will undoubtedly witness the re-introduction of the Railway Rates Bill, which is designed to impose certain restrictions, in the interest of traders, upon the often monopolist powers exercised by railway companies. Should that Bill at last become law, it will do much to limit and remove the more flagrant abuse of preferential rates, of charges in excess of parliamentary powers, and of terminal and other charges of which no proper account has been given hitherto. But the Bill is not designed to abolish or modify the maximum rates and fares authorised to be taken; and if these maxima, or any near approach to them, are continued, the position of the trading community, as a whole, is scarcely likely to be much improved. There is no doubt that there is substantial accuracy in the complaint that these charges are much higher than the now extremely narrow margin of industrial profits usually permit. It would, however, be well for the railways to consider, in their own as well as in the traders' interest—for in this matter they are identical—whether they would not be likely, in many cases, to develop business by a lower range of rates and fares. America has done wonders in this direction, and the railway interests of the United States were probably never in a more healthy condition than they are in to-day.

SHIPBUILDING.

There are no fewer than fifty-five ports in England and Wales at which shipbuilding operations are carried on, nineteen in Scotland, and three in Ireland. At these ports the net tonnage of the vessels built, not including those for foreigners, in 1886 is officially returned in the "Annual Statement of the Trade and Navigation of the United Kingdom," as follows:—

	No. of vessels.	Tonnage.
England and Wales	447	162,136
Scotland	203	112,072
Ireland	21	18,792
Totals	671	293,000

which represents the net addition to the register of the United Kingdom in that year. In the same year the tonnage of the merchant navy of the United Kingdom as a whole was officially returned at 7,321,335 tons, being 66,000 tons less than in the previous year. It appears, therefore, that after making due allowances for vessels removed from the register by wrecks and otherwise, the vessels added in 1886 were inadequate to keep up the register at its 1885 level.

Wooden ships or boats are still built at a good many ports. In 1886 there were no fewer than 256 vessels constructed of wood, having a total net tonnage of 14,363 tons, or, in other words, averaging rather under 60 tons each. The principal ports for wooden shipbuilding are Brixham, Dartmouth, Grimsby, Lowestoft, and Rye.

In steel, the number of vessels built on British account in 1886 was 194, of the aggregate tonnage of 141,020. Of this number 39 were sailing and 155 were steam vessels. The sailing vessels averaged 814 and the steam vessels 705 net tons each. There has been a disposition during the last few years to build in iron sailing vessels of larger dimensions than usual for cargo-carrying purposes. Of such vessels the number constructed in 1886 was 93 for British owners, their net tonnage being 92,337 tons, while 122 vessels were built as steamers, with only 44,923 net tons.

The number of vessels built in the United Kingdom for foreigners in 1886 was 65. Their net tonnage was 38,528 tons. Nearly one-half of the whole were built at Glasgow. The total number of vessels built in British possessions in 1886 was 491, of 43,010 net tons. Of this number 332, of 35,113 net tons, were built in Canada, and 106 vessels, of 5,541 tons, in Australasia. The Colonies evidently do not threaten to seriously compete with the mother country in shipbuilding just yet.

So far as the returns are at command, it would appear as if the amount of shipbuilding done in 1887 was appreciably greater than in 1886. The amount of work done on the five chief shipbuilding rivers in Great Britain during each of the last two years has been as under:—

	1887. Tons.	1886. Tons.	Increase in 1887. Tons.
The Clyde	185,362	172,440	12,922
The Tyne	104,284	82,757	21,527
The Wear	85,214	61,399	23,815
The Tees	35,346	20,476	14,870
The Mersey	10,282	20,302	Decrease. 10,020
Totals	420,488	357,374	63,114

The total increase of shipbuilding during 1887, so far as can be ascertained at present, is about 100,000 tons over 1886. The aggregate tonnage launched in iron and steel in 1887 was about 580,000 gross tons, the total number of vessels being 630, and the average tonnage per vessel being 921. On the Wear, however, the average size ran up to 1803 tons. There is a good deal of work on hand at present, and further orders are expected, so that shipbuilders can look forward hopefully to the immediate future.

TEXTILES.

Cotton.—The cotton trade can hardly be said to have had a satisfactory year, although the average prices realised have been a trifle better than those for the previous twelve months. In yarns, the difference has been about 3d. to 4d. per lb. Some of this difference, however, has been lost to the trade by the higher prices paid for the raw material. The average price of raw cotton over the year has been £2. 9s. 10d. per cwt., as compared with £2. 9s. 3d. in 1886. There has been a great deal of keen competition during 1887, both in the spinning and in the weaving departments of the trade. But it has been found difficult to make profits at the present comparatively high range of wages. There is no industry in which the operatives have obtained greater concessions within recent years than in that of cotton. The labour is still, however, relatively cheap, because so much of it is performed by women and children. The manufacturers of Lancashire are looking forward to being benefited by the completion of the Manchester Ship Canal, now fairly undertaken; but while this event will somewhat reduce their cost of transport, and thus place them in a better position to compete with foreigners, the competition that exists among our home manufacturers is too severe to be likely, under existing arrangements, to allow of their receiving any considerable profit. There has, indeed, been far too great an extension of productive resources in this industry, owing mainly to the facility with which mills could be run up under the Companies Acts, and the natural effect of over production has followed. The exports of cotton yarn from this country have been reduced largely within recent years. They were as high as 271 million lbs. in 1884; but in 1886 they had fallen to 254 millions, and in 1887 (first eleven months) they were only 228 millions. It is true that piece goods are much better, the exports having shown a steady increase; but while the development of the trade within recent years has been wholly in the direction of weaving, there was a fall of the average export prices of cotton yarn, from 13·25d. per lb. in 1880 to 10·84d. per lb. in 1886, and with an almost entire absence of profits in this branch of the trade.

The course of the export trade gives as good an idea of the condition of textiles generally as it is possible to obtain. In order that the concurrent movement of allied industries may be appreciated and compared, we have included them in the analysis that follows.

In yarns the business done in 1887, so far as it is illustrated by our exports, has not been equal to that done in 1886, as the following figures show:—

	1887. lbs.	1886. lbs.
Cotton	228,000,000	235,000,000
Jute	21,000,000	29,000,000
Linen	15,000,000	15,000,000
Woollen	37,000,000	42,000,000
Totals	301,000,000	321,000,000

The values of these different descriptions of yarn in the same years come out as under:—

	1887. £	1886. £
Cotton	10,325,467	10,631,767
Jute	207,414	253,071
Linen	855,417	856,198
Woollen	3,628,952	4,087,636
Totals	15,017,250	15,828,672

Dividing the quantities into the values for each of the two years, the results obtained show that the average prices per lb. were:—

	1887. Per lb. d.	1886. Per lb. d.
Cotton	11·0	10·8
Jute	2·3	2·5
Linen	13·6	13·6
Woollen	23·5	23·3

These figures show a slight improvement in woollen yarn, a decline in jute, a stationary attitude on the part of linen, and a slight improvement in cotton yarns. Prices, however, are still remarkably low. The following table shows the prices of yarns at different dates for the last 47 years, as calculated from the export returns of the Board of Trade:—

Year.	Cotton. Per lb. d.	Linen. Per lb. d.	Jute. Per lb. d.	Woollen. Per lb. d.
1840	14·39	11·14	—*	28·63
1845	12·37	10·93	—*	27·22
1850	11·66	11·61	—*	25·26
1855	10·44	12·32	—*	22·90
1860	12·00	13·85	2·90	32·46
1865	23·98	16·54	3·99	40·31
1870	18·92	14·42	3·72	33·73
1875	14·66	15·95	3·40	38·58
1880	13·25	14·25	3·33	30·33
1883	12·25	14·36	3·05	23·41
1886	10·8	13·6	2·5	23·3
1887	11·0	13·6	2·3	23·5

* Cannot be given for those years.

It will be noticed that although the prices that have prevailed over the last two years are exceptionally low, they are not the lowest in the history of the cotton, linen, and woollen industries. The year 1855 carries off the palm in this respect. Jute, however, has been lower in 1887 than it had ever been before. The exceptionally high prices shown for cotton and linen in 1865 are, of course, due to the American war. The lower prices of 1887 are also, of course, concurrent with a cheaper cost of production.

Digitized by Google

In piece goods there has been comparatively little difference between the years 1887 and 1886. The quantities and values compare as under :—

	1887. Millions of yards.	1887. Value. 1=1000. £	1887. Average per yard. d.	1886. Millions of yards.	1886. Value. 1=1000. £	1886. Average per yard. d.
Cotton ...	4,448	46,933	2·53	4,471	46,220	2·48
Jute	220	1,873	2·04	194	1,625	2·01
Linen ...	149	3,836	6·17	151	3,837	6·09
Woollen..	232	15,159	15·7	229	14,770	15·5
Totals..	5,049	67,801	—	5,045	66,452	—

This little table, small and insignificant though it may appear, is really very valuable, for it shows that there has been a real revival in prices during the past twelve months. This revival appears in all textile piece goods alike, but it is most noticeable in linen and woollen goods. The improvement is little more than fractional, but in the textile industries prices and profits alike partake of this character, and a tenth of a penny per yard will often make all the difference between a good dividend and no dividend at all. The recent course of prices in textile piece goods is one of the most remarkable developments of economical production of which it is possible to cite examples. Plain cotton piece goods ranged between 5·79d. and 3·13d. per yard between 1864 and 1876. From the latter year they never got above 3d. per yard, but they did not fall below 2½d. until 1884-85, and the slight improvement in price in 1887 still leaves cotton piece goods at a lower level of prices than has been known in the history of the trade.

THE SUGAR INDUSTRY.

The sugar trade has claimed a large amount of attention during the past year, and especially during the last two months. The Sugar Bounties Conference, which held a number of sittings, resulted in a convention, under which the representatives of the several countries delegated engaged to propose to their several legislatures that no bounty, open or disguised, should be given on the exportation of sugar, and there are other clauses under which the contracting powers undertake not to impose duties on sugars, or to accord to raw or refined sugars for export any drawback, reimbursement, or abatement. It is hoped and believed that the result of the Conference will, on the whole, be advantageous to the British sugar industry. The course of that important manufacture for the last twelve or fifteen years has been extremely variable. Our exports of cane sugar from our own Colonies have fallen from 5½ million cwt. in 1879 to 3¼ millions in 1886. The imports of cane sugar from other countries have fluctuated, since 1872, between a maximum of 9 millions and a minimum of rather over 6 million cwt., while our imports of raw beet sugar have advanced in the same period from less than 2 million to over 8 million cwt. The prices of sugar in the middle of December have been as under for each of the last three years :—

	1887. Per cwt. s. d.	1886. Per cwt. s. d.	1885. Per cwt. s. d.
West India brown...	14 3 to 14 6	10 6 to —	14 6 to —
Java, off coast.....	17 3 „ —	13 6 „ 13 9	17 9 „ 18 3
Beet, 88 per cent.	15 3 „ —	11 1½„ —	15 7½„ —
French loaves.....	18 9 „ —	15 6 „ —	20 0 „ —

Both the imports into and the deliveries from the United Kingdom have been greater in 1887 than in 1886, though not so considerable as in 1885. The quantity in stock at the present time is larger than in either of the two previous years.

THE CHEMICAL INDUSTRY.

The past year has been rather more hopeful for the chemical trades, although prices have been too low to permit of a fair profit except in certain cases. In the alkali trade the volume of business done in the first eleven months of the year was under that done in 1886 to the same date, but the decline has been almost entirely in the exports to the United States. Taking chemical manures and other chemicals besides alkali, there has been an increase in the exports for the eleven months of about £320,000. Prices for the month of December in each of the last three years compare as under :—

	1887. Per ton. £ s. d.	1886. Per ton. £ s. d.	1885. Per ton. £ s. d.
Soda, crystal	2 7 0	2 9 6	2 10 6
	Per cwt.	Per cwt.	Per cwt.
Saltpetre, refined	1 0 9	1 1 0	1 2 6
Turpentine, American	1 8 6	1 6 3	1 7 0

One of the growing features of the chemical trade is the production of tar on a large scale in the manufacture of coke and in the process of iron smelting. The same new developments have affected the price of ammonia, so that these residual products have not been nearly of the same value to gas corporations as formerly.

THE SHIPPING INDUSTRY.

In seeking to fix the progress or regress of any particular trade or industry, there is no more excellent plan than that of borrowing concrete cases from available sources. Adopting this plan, we find that the Peninsular and Oriental Company, with their high prestige and admirable vessels, have had to complain of a very bad year. The inter-Colonial trade, and especially that between Bombay and China, has been remarkably unremunerative, owing to foreign and bounty-fed competition. To India the rates have also been abnormally low, as was found by the same company only so recently as October of this year, when their new steamer, the "Victoria," did not earn more than 10s. per ton on her Bombay freight. The tea rates from China have only been 20s. or 25s. per ton, whereas a year ago they were as high as 50s. It is, however, a set-off to some extent to these low rates, that within the last month or two it has been possible to find full cargoes outwards to India. The low rates of freight have not, of course, been always, or entirely, coincident with corresponding losses of profit. The working of steamships has been greatly economised even during the last few years. The economy has occurred in almost every branch of outlay. The reduction that has occurred in the cost of labour is indicated by the fact that while in 1877 there were 3·35 persons employed in the foreign trade per 100 tons of shipping, this proportion had in 1886 fallen to about 2·5 per 100 tons. In other words, there was a reduction in the ten years of about 25 per cent. in the number of hands required to navigate a given tonnage of steam shipping. Within the same interval there has been a very material reduction in the cost of fuel, owing to the economy introduced in engine power. This economy will, of course, vary in different classes of steamers and in different descriptions of coal. But taking one trade with another, it will most probably average about 1lb. per i.h.p. per hour. The effect of such economies is reflected in the working expenses of all the great shipping companies. The Peninsular and Oriental Company, for example, have found that, whereas in 1877 their expenses were at the rate of 22s. 3d. per mile navigated, including insurance and depreciation, the average had fallen to 18s. in 1886-87. On a single voyage to and from India, this would represent some £4,000, which is, of course, a very material factor. Steamships with the old compound engines, consuming over 3lb. of coal per i.h.p. per hour, are necessarily handicapped in competing with new steamers having triple expansion engines, and consuming considerably less than 2lb. Among trading vessels, therefore, there is much real distress and depression, which is only likely to be overcome by the somewhat costly, but apparently inevitable, process of introducing the newest improvements devised by the engineer and naval constructor.

During the first eleven months of 1887, the amount of business done in the shipping trade of the United Kingdom, as regards the entrances and clearances from our ports, was larger than in either of the two preceding years, the total volume having been—

	Tons.
In 1887.....	51,500,000
„ 1886.....	49,500,000
„ 1885.....	50,700,000

There has, in 1887, as in each of the two previous years, been a considerably larger tonnage of clearances than of entrances. The tonnage of vessels entering and clearing from and to the principal countries with which our business was transacted was in each of the last three years as follows (1 = 1000 tons) :—

	1887.	1886.	1885.
United States	7517	7390	7212
France	5258	5171	5087
Germany	4457	4451	4571
India.....	3107	3175	3295
Spain	3460	2949	2828
Holland	3135	2909	2933
Canada.....	1925	1982	1968

It will still be some months before we have particulars of the values of the exports from different ports in 1887, but those for 1880 and 1886 are compared in the following table :—

Statement showing the value of the total exports of the produce of the United Kingdom from each of the principal ports, in the years 1880 *and* 1886. (1 = 1000).

	1880. £	1886. £	Increase in 1886. £	Decrease in 1886. £
London	52,600	46,125	—	6,475
Liverpool	84,029	86,029	2,000	—
Hull.....	18,572	15,643	—	2,929
Glasgow.....	11,828	12,386	558	—
Southampton	9,306	5,385	—	3,921
Cardiff	4,161	3,850	—	311
Newcastle-on-Tyne.	4,528	3,668	—	860
Grimsby.....	7,236	7,233	—	3
Goole	3,003	4,870	1,777	—
Dover	1,396	1,258	—	138
Bristol.....	1,763	1,210	—	553
Middlesbrough	2,026	2,006	—	20
Newhaven	1,770	1,725	—	45
Folkestone.....	1,265	1,403	138	—
Leith	2,819	2,570	—	249
Swansea.....	828	2,837	2,009	—
Totals.....	207,220	198,198	6,482	15,504

Net decrease, £9,022,000.

The above table shows a remarkable falling off in the value of the produce exported from the principal ports except Liverpool, Goole, and Swansea. The decline in the case of London is especially noticeable, and suggests whether the Thames has not found its facilities for export trade, notwithstanding its fine system of docks, eclipsed by those of ports that are nearer to our great manufacturing centres.

There is almost of necessity, in a trade so varied and extensive as the shipping trade of the United Kingdom, a good deal of unavoidable movement of vessels in ballast. The tendency is for vessels to come to this country to receive cargoes in greater measure than that in which they carry cargoes hither. In other words, the clearances of vessels in cargoes is greater than the entrances of vessels in cargoes, notwithstanding our enormous import trade. Here, however, we are met by the difficulty to reconcile the greater tonnage of exports from the United Kingdom with the well known excess of the value of imports over that of exports. There are two ways of explaining this apparently anomalous and unlikely condition of things. The first explanation is that the exports from the United Kingdom are very largely of commodities that are very heavy and very bulky in proportion to their value, as, for example, coal, coke, pig iron, and steel rails. These necessarily occupy much more space and weigh much heavier than would Colonial produce, cereals, or almost any other commodity that enters largely into our import returns. The second explanation is that the imports into the United Kingdom are valued at the port of import, and therefore include profits and cost of freight, whereas the exports are valued at the port of export, and therefore minus the cost of freight. This, of itself, makes a very remarkable difference. The income from shipping in the United Kingdom has been estimated at over 50 millions sterling a year. Some have put it as high as 65 millions annually. If it is assumed that one-half of this amount belongs to the export trade, the difference of value against exports would be reduced from 81¼ millions to about 51 millions, and the difference in the value of our imports relatively to their bulk and weight is quite sufficient to account for the remainder.

GENERAL EXPORTS AND IMPORTS.

The amount of business done during the past twelve months has been very satisfactory, when compared with some preceding years, although still a considerable distance from equalling the maxima of a few years ago. The full returns for the year 1887 are not yet available, but a sufficiently accurate idea of the year's trade may be obtained by taking the twelve months ended November 30th, instead of the calendar year. In this way, we find that our exports compare as under :—

Value of exports of British and Irish produce and manufactures for the year ended 30th November, 1887, *compared with the year* 1886 :—

	1887. £	1886. £	Increase or decrease in 1887. £
Animals.....	729,308	546,288 +	183,020
Food	9,282,114	9,552,294 −	270,180
Raw materials.....	12,569,497	12,431,620 +	137,877
Textiles	106,424,184	105,329,277 +	1,094,907
Metals	34,163,601	31,703,398 +	2,460,203
Machinery	10,971,189	10,073,192 +	897,997
Apparel	10,195,427	9,764,049 +	431,378
Chemicals	6,917,267	6,726,858 +	190,409
Other articles	26,813,899	26,387,937 +	425,962
Total	218,066,486	212,514,913 +	5,551,573
Foreign and Colonial exports	58,489,259	56,683,894 +	1,805,365
Grand total ...	276,555,745	269,198,807 +	7,356,938

The above return is, on the whole, extremely gratifying. There is an increase in every item except food, and an especially large increase in our two greatest industries—metals and textiles. The imports into the United Kingdom during 1887 are in the next table presented and compared in a similar manner.

Value of imports from foreign countries and British Possessions in the year ended 30th November, 1887, *compared with* 1886 :—

	1887. £	1886. £	Increase or decrease in 1887. £
Animals.....	6,133,024	7,195,135 −	1,062,111
Free food	114,368,708	110,741,968 +	3,626,740
Dutiable food	25,764,267	25,435,008 +	329,259
Tobacco	3,383,119	3,844,457 −	461,338
Metals	15,777,484	15,145,438 +	632,046
Chemicals.....	7,636,597	8,009,278 −	372,681
Oils.....	6,143,822	6,067,830 +	75,992
Raw textiles.....	78,670,114	70,691,022 +	7,979,092
Other „	34,283,973	35,561,692 −	1,277,719
Manufactures	53,915,972	53,837,528 +	78,444
Miscellaneous	12,695,241	12,877,036 −	181,795
Total.....	358,772,321	349,406,392 +	9,365,929

It will be observed from these returns that the increase in our imports has been considerably greater than that

which has occurred in our exports. The increase that is likely to be most regretted—perhaps, indeed, the only one that need provoke any such feeling—is the increase in our imports of manufactures, which, however, only amounts to £78,444. In our food supplies there is an increase of about four millions, excluding animals. The average imports of food per head of the population amounted in 1887 to about £4.

PRICES OF IMPORTS.

It is one of the most essential elements of prosperity and activity of trade, in a manufacturing country like England, that she should be able to purchase the raw materials of her industries at reasonable prices. During 1887 the range of prices, taken as a whole, has been similar to that of the previous year; but in some there has been quite a notable reduction. This is especially the case with esparto, timber, tallow, ivory, hides, goats' wool, and flax; but hemp and cotton have been rather higher in 1887, and this has been the case also with ordinary wool. In the whole range of raw materials, however, the average of 1887 was rather under that of the previous year. The above tables show the average import prices and quantities of raw materials and manufactured articles imported in 1887 and 1886, separately distinguished.

So far as the above figures enable an estimate to be formed—and they are really very valuable for that purpose—it is clear that in our leading industries we have experienced exceptionally keen competition during the past year. There has been an appreciation of any moment in the values of iron only. In other manufactures prices appear to have ruled lower than in 1886; but this is of course a matter that is largely affected by the character and quality of the products, which may not be quite the same in the years compared.

IRRIGATING MACHINERY ON THE PACIFIC COAST.*

(Concluded from page 4.)

Pit Pumps.—In Fig. 8 is shown the common arrangement of what are called pit pumps in California. When the water rises in the wells within suction distance of the surface horizontal pumps similar to that shown in Figs. 6 and 7 are employed; but when this distance exceeds 20ft. rectangular pits are sunk from 10ft. to 60ft. deep, as shown in Fig. 8. Two or more tube wells T are sunk from 50ft. to 150ft. below the bottom of the pit; and in these are inserted the suction pipes S, leading to the suction box A, on which the pump P is mounted. The driving shaft D is supported in thrust boxes B B, and when of several lengths is connected by clamp couplings. The pump being balanced, there is no thrust except that caused by the weight of the spindle and wheel. This is taken up in the thrust box E, which has an annular oil chamber, and collars that perform the double office of supporting the spindle and sealing the joint to prevent the entrance of air, thus taking the place of the common packing gland. The air vessel H is made rectangular in plan, with the two-fold object of giving it elasticity, so that it shall not be broken by water-shock in stopping, if the air cushion should fail, and also of allowing the valve to open fully. The uptake pipe U is usually made of sheet iron coated with zinc and soldered at all joints. It is found expedient to have the area of these pipes at least four times that of the pump discharge, when the head exceeds 50ft. A charging pipe N is carried up to the surface, where an air pump or steam ejector is employed to fill the pump. Among the principal objects aimed at in the present pumps are the greatest possible simplicity; easy separation into parts, so that the machinery can be raised out of the pits or lowered into them without tackle; access to all interior parts; and the highest efficiency possible under the circumstances. The circumferential speed of the pump wheels in feet per minute being approximately 500 times the square root of the head in feet, wheels of 24in. to 30in. in diameter can be used for heads up to 100ft. without the speed of the shafts exceeding the rules of safe practice.

Low Lift Centrifugal Pumps for Land Reclamation and Irrigation.—As the Sacramento and San Joaquin rivers approach the ocean, the sedimentary plains bordering upon them sink below the level of the winter and spring floods, and hundreds of square miles become covered with water from 1ft. to 10ft. deep. These plains are called tule lands, from a kind of soft reed of that name which covers the whole surface where water stands. When drained of water and cleared of the tule growth the soil is a bed of vegetable compost of such surprising fertility and strength that crop after crop can be grown in the same year. It is mainly on these tule lands that are produced those prodigious crops of wheat, barley, potatoes, &c., which have rendered California famous in agriculture. These fertile lands, lying near San Francisco, and reached by water, rail, and roads, are of great value, and their reclamation has been the object of costly and extensive efforts. The work has been attended with great difficulty, and the larger part of the area once drained has subsequently been lost again, in consequence of the fluctuations of the rivers being so uncertain, and the period of exact observation having not yet been long enough for determining the levels of high floods. Moreover, placer mining has sent down silt enough to change nearly all the levels during the past twenty years. The embankments when made of peat have not weight enough to resist the pressure of the water; and being buoyant are sometimes floated away bodily. They are so porous that the percolation is enough to require pumping machinery in most cases; besides which the rainfall in winter and spring has to be pumped out when the rivers are higher than the lands. The uncertainty as to the quantity of water to be raised, the absence of permanent foundations, and the speculative nature of the attempts to reclaim the land, require machinery not merely of a cheaper kind than elsewhere, but also of quite a different character from that employed in other parts of the world, where land drainage is mostly performed at central pumping stations constructed for a definite and permanent duty. The tule lands are divided into districts, for each of which there is an engineer, by whom all plans and estimates for pumping machinery are closely examined; and a guarantee of efficiency is required. Besides the reclamation of the tule lands, there is also the nearly analogous duty of pumping from rivers to irrigate what are called the bench lands, lying from 15ft. to 30ft. above the water level. The limit of the height to which water can profitably be raised by machinery for ordinary crops at the present price of fuel and cost of machinery may be set down at 25ft. to 35ft. Most of the pumps now in use are of small size, such as may be driven by threshing engines of 25 to 35 i.h.p., and are of the types already described. In Fig. 9 is shown a reclamation pump of the usual construction, which is mounted on a framing made of Oregon pine. This is a hard, stiff kind of timber, almost as strong as ash, straight grained and without knots, of which beams can readily be obtained 50ft. long and 24in. by 12in. section. For the smaller pumps iron bed plates are employed; and also for the larger, wherever the extra cost is not objected to; but the timber frames answer very well, provided the machinery is so arranged that its working shall not be interfered with by such flexure as the timber framing is liable to. The centrifugal pump is arranged with its spindle horizontal; and in order to avoid end thrust the wheel is made with open vanes. The interior of the casing is turned smooth; and the wheel is also carefully turned after having been fixed on its spindle. The engine E has two single acting cylinders, of which the diameter is usually equal to two-thirds that of the discharge pipe D from the pump, when the total lift is not to exceed 20ft. The driving shaft is of steel, and is connected with the engine by a compression coupling N. The bearing B is mounted on a planed iron seating, so that it can be slid back when the pump gland requires packing. By thus supporting the driving shaft close up to the pump, no bearing is required on the suction side of the pump, which would be objectionable on account of the obstruction it would offer to tule roots, weeds, straw, and other rubbish that finds its way into the pump.

All the parts have to be arranged for allowing of ready access to the interior of the pump and pipes. The suction pipe S is slung by a chain, so that it can be lifted away from the pump in case of the foot valve at F becoming choked. The inlet nozzle of the pump casing can be cleared from ordinary obstructions by removing the hand plate at H. The two side plates of the pump casing are easily removed. Whenever the wheel becomes clogged with tule roots, the suction pipe S and the plate on the same side are loosened and swung aside; the coupling N is also loosened, and the wheel can then be drawn out at the suction side to be cleared. The time of the whole operation need not exceed ten minutes. The pump is of a semi-portable character, and adapted to most cases, but not to all. When the head varies on the delivery side, as it does sometimes from 1ft. to 14ft., it is evident that a pump arranged in this manner would not answer. The pump and engine must of course stand above the water level, which varies both inside and outside the embankment. There is no means of working economically against a low head, except by submerging the pump wheels. The height of the suction lift must be more than the variation of the water inside the embankment. Consequently when the water is low on both sides of the embankment, as much as two-thirds of the work may be lost, since the syphon action of the discharge pipe cannot be relied upon. A bottom discharge for the pump would remedy this difficulty in a measure; but it would involve the addition of an air tight sluice valve in the discharge for starting the pump, and also a pneumatic or steam charging apparatus. The syphon action of the discharge pipe soon ceases, unless there is some means of continuously exhausting the air given off by the agitation of the water in the pump. To connect the discharge pipe with a condenser, or to employ other means of exhausting the liberated air, introduces a complication not compatible with the attendance commonly received by such pumps on the Pacific coast.

Submerged Pumps.—In Fig. 10 is shown a vertical pump of the Whitelaw type, of which several have been constructed on the Pacific coast from the writer's designs; it is one of the cheapest arrangements, and places the machinery well above the water, excepting only the pump wheel, which is submerged. The engine and boiler are placed on the top of the embankment M, and are generally raised 1ft. to 2ft. above the ground; the embankment itself is in most cases wide enough for a roadway on the top, whereby fuel can be hauled or access obtained to the works when the whole country is flooded. The pump casing is a vertical cylinder, having a suction nozzle at the bottom, and a flange at the top by which it can be suspended from the bottom of the trough T. The pump spindle is supported in three bearings as shown, and is driven by a band from the engine E. A pair of bevel wheels are sometimes employed at the top of the spindle, so as to avoid twisting the band. The wheel or runner R is curved upwards, so that the tips of the vanes terminate parallel with the sides of the pump casing. Inside the casing is inserted a central sheet iron cone C; and the current of discharge water, ascending through the widening annular space between the cone and the cylindrical casing, loses its velocity gradually as the area of passage enlarges; while at the same time the whirling motion with which it quitted the wheel is checked by means of curved blades B fixed on the outside of the cone, whereby the current is deflected upwards. The water has to undergo deflection through one more right angle in a pump of this kind, with curved runner discharging parallel to the axis, than when the discharge is at right angles to the axis. But although the efficiency may thereby be impaired to the extent of as much as 10 per cent., this is often of less importance than the countervailing advantages gained with submerged pumps. There is no charging to be done, no valves, and no pipes. Tule roots and other obstructions pass freely through the runner, and are thrown out against the pump casing, where they are soon worn away. The pump shown in Fig. 10 is for raising 400,000 gallons an hour, the cylindrical casing being 40in. in diameter, and the engine capable of developing 35 h.p. Similar pumps have been erected on the San Joaquin and the Colorado rivers, and have raised 660,000 gallons an hour. Nearly forty years ago Mr. Whitelaw's experiments at Johnstone, near Glasgow, demonstrated that a high efficiency could be attained with pumps arranged in this manner. The only impediment is in utilising the energy of the water after it leaves the wheel R. If the velocity is destroyed by impinging against the body of water in the uptake, the efficiency for low heads will not exceed 40 per cent. The pump shown was much improved by inserting above the wheel R the cone C having curved deflecting blades B, which change the motion of the water from a horizontal to a vertical direction. With careful attention to the various conditions accompanying the action of centrifugal pumps, this arrangement has much to recommend it, especially in economy of first cost. In the Louisiana district, about the mouth of the Mississippi river, pumps of this kind are extensively employed for low lifts, the action being analogous to that of a turbine water wheel inverted, and centrifugal effect being almost disregarded.

Bulkhead Pumps.—In Fig. 11 is shown a plan of a pair of centrifugal pumps arranged for driving the water through a

bulkhead against a head varying from nothing to 10ft. The pumps are submerged to a sufficient depth to require no charging, and consequently no valves are necessary. The area of the two discharge nozzles is 150 sq. in. each, and the quantity of water delivered is 500,000 to 800,000 gallons per hour. This arrangement is the least expensive that can be adopted for land drainage or irrigation; it was suggested by a Dutch engineer who had erected similar works in Java, and has been found in every way satisfactory. The embankment is cut through, and a strong timber bulkhead A is erected across the gap. The pumps P P are placed immediately behind the bulkhead, with their discharge nozzles projecting through it. Flap valves opening outwards are hung over the discharge nozzles at D, to prevent back flow through the pumps when not working; in dry seasons they are sometimes opened for letting water flow through for irrigation. The vertical pump spindles are driven by bevel gearing from a horizontal shaft. The engine E is single acting, with two cylinders of 10in. diam., and its speed is 300 revolutions per minute. The machinery shown in Fig. 11 was erected during 1885, on the Sacramento river, 75 miles from San Francisco, for draining tule lands.

Pumps driven by Bands.—In Fig. 12 is shown an arrangement for raising 900,000 gallons per hour by means of two centrifugal pumps driven by bands. The two discharge nozzles from the pumps are each 115 sq. in. area. The pumps have open wheels, and double suction pipes S, one on each side, not joined; each pipe has a foot valve of 100 sq. in. area. The suction pipes themselves serve as the supports for the pumps, being made strong and with large flanges to rest on the timber framing. The sump U is 6ft. deep, and the suction pipes dip into it to different depths, so that when the water supply falls short the higher pump will run empty or be disconnected, leaving the lower only to continue working. The average head in this case being only from 3ft. to 5ft., it was considered that the water could be driven more by direct push than by centrifugal force. The pumps were constructed accordingly with smooth iron vanes, bolted to a square extension on the pump spindle. The throats of the suction inlets were made very sharp, and brought in as close as possible to the inner tips of the vanes. The discharge pipe D carried through the embankment is 30in. bore, and is set with slope enough to let the water run down it from the pumps when the head at the discharge outlet is not too high. The engine is placed level with the top of the embankment, 15ft. above the pump floor. The whole of the machinery is mounted on wooden framing, being on treacherous ground; it was erected during the winter, when no other foundation was possible, and gives promise of standing well. Movement takes place, the whole structure sometimes going together, but excellent service has been done. The work was planned and its erection superintended by Mr. J. P. Van Loben-sels, a gentleman well acquainted with drainage work in Holland, and of considerable experience in such engineering matters. It drains the leakage and rainfall from 8000 acres of land, surrounded by embankments 15 miles long; the estate is on the Sacramento river, and is one of the best maintained in the valley. The embankments are of a superior character, being for the most part made of clay or loaded with clay; they sink, however, and have continually to be raised and strengthened. This plant has since been increased to a capacity of 2,400,000 gallons an hour, by the addition of a pump of 30in. bore, driven by a compound condensing engine.

Single Acting Engines.—For pumps directly geared to engines, the practice differs somewhat from that of English makers, but is much in advance of the methods employed in the Eastern States, unless it be in the case of one firm there, who have copied Messrs. Gwynne's pumps and drive them with pairs of single acting engines; of these, however, present knowledge will not permit comparison. The author at first employed single acting engines, as shown in Fig. 13. These are especially suited for driving centrifugal pumps where permanent foundations are wanting. Being wholly self contained, working at high speed with reasonable economy, and occupying but little space, they bid fair to take the place of double acting engines for the purpose. As the thrust on the connections and bearings is in one direction only, there is no compensation to look after, and no shake or knock. There are no glands to pack, and scarcely any oiling to do. The valves are of the oscillating cylindrical kind, the steam entering at S round the outside of the valve V, and exhausting through its interior. The connecting rods are of brass, made as light as possible. The crank shaft is of steel, with cranks opposite, and with counterbalances bolted on at C. The valve gear G is of the simplest construction, consisting merely of an overhung crank and connecting link; the eccentricity of the crank can be readily adjusted for regulating the lead of the valve, or reversed for running the other

Digitized by Google

way. Automatic gear for controlling the speed by the cut-off is sometimes applied; but for regular duty, like pumping, the throttle valve adjusted by hand is quite as good, and is better understood by attendants. The crank chamber M is partially filled with a bath of water and oil, which is splashed by the cranks into all the bearings and also into the cylinders; no other oiling is required, except of the valve link, which is made hollow so as to be oiled at both ends while in motion. The cylinders are surrounded by a rectangular casing which serves as an air jacket, so that but little heat is lost by radiation. The objections to this class of engines are their dimensions in the direction of the crank shaft, a want of steam economy, and the low duty consequent upon the compression at the top of the upstroke, required to keep the bearings in contact and to avoid knocking. The difficulties that have been met with during the past ten or twelve years in maturing these single acting engines are considered by the writer to lie, not in the principle or mode of working, but in providing a suitable connection for transmitting the power from the pistons to the cranks on the driving shaft.

Differential or Compound Engines.—In later practice, the engines adopted are of the differential or compound type, as shown in Fig. 14. The steam is admitted first into the annular space A surrounding the trunk T, and after acting in the upstroke underneath, the steam is expanded upon the top of the piston P, acting then on the difference of area between the two sides of the piston, and expanding three times or more. The engines are made without stuffing boxes, except for the valve stems; and oiling is performed by enclosing the parts, as in the single acting engines. In this way a good expansion is attained with a single and simple slide valve; and the engine is reduced to the fewest and simplest parts possible.

Hydraulic Rams.—Owing to the extensive use of small hydraulic rams on the Pacific coast, some experiments were commenced at the beginning of this year by the author in conjunction with Messrs. W. T. Garratt & Co., engineers, of San Francisco, in order to see whether larger machines of the kind could be constructed for meeting the requirements of raising water from the mountain streams. As yet these experiments are by no means completed; but the author believes some of the constructive features are of sufficient interest to warrant their being appended to the present paper. The various phenomena that arise in employing the impact of water in hydraulic rams are such as to render the matter one of experiment, unless in cases where the intermissions or valve movements are controlled by independent machinery, that is, by some power independent of the flow or issue of the water passing through the ram. The latter is unquestionably the correct method, if the supplemental mechanism can be made durable and reliable, as no doubt it can. The first experiments made were with small rams having inlet pipes from 2in. to 3in. diam., as shown in Fig. 15, in which I is the inlet pipe and D the discharge pipe; C is the check or foot valve, and A the air vessel; and V and E are the escape valves fixed on the same stem. The two valves V and E being nearly balanced, the difference of their areas constitutes the measure of the upward or closing force, which is of course much less than in the case of a single valve. The valves fall by their weight in the usual manner; and are raised partly by the stream rushing out round the upper valve V, but mainly by the upward pressure of the issuing current against the curved shield S fixed on the valve stem. In working it was found that accurate adjustment was required to suit the head or fall of the driving water; and also that the shock was too great for the safety of large rams. The method was therefore changed to that shown in Fig. 16, in which the two escape valves V and E are arranged to pass up freely through their seats, and are stopped by an air cushion at the top. The waste water nearly all escapes at the upper valve V, small outlets only being provided in the lower valve E for permitting sand to escape if any should be carried into the machine. The closing is effected, as before, mainly by the upward pressure of the issuing stream against the curved shield S. When the valves are shut upward in closing, the shield enters the air chamber above it, in which it fits as a piston, and the momentum is thereby checked without the least shock. An air cock is inserted in the top of the air chamber at L, for regulating the amount of resistance offered by the air cushion. Additional weight if required is added on the top of the valve stem at K; it is found, however, that the higher the head the less is the weight required for opening the valves. Snifting valves were at first applied, but seemed unnecessary. Rams arranged in this manner work without noise or jar, and give a high efficiency for forcing four to five times the height of the propelling head, and are suitable in most cases for irrigating purposes; but when the resistance is increased, the elastic blow or percussive impulse of the current is not enough to raise the check valve C against the increased area caused by its lap. In Fig. 17 is shown another arrangement of hydraulic ram, in which the escape valve is opened by independent mechanism. The water enters at I, and the waste escapes at the bottom through four holes, which are alternately covered and uncovered by the four wings of the oscillating valve V, which is mounted on a spindle S. The valve is opened by means of the water wheel W and a tappet motion. The two tappets coming in contact at each revolution of the water wheel open the valve to such an extent as may be determined by an adjusting set screw. As soon as the tappets disengage, the valve is closed by the reaction of the issuing stream against its curved ribs or vanes, the motion being arrested by the tail of the tappet arm. In this manner the motions of the waste valve V can be controlled at will, and a greater efficiency attained than with the ordinary method of employing the force of the issuing stream for closing the valve by lifting it. Experiments have not yet been made to determine the most effective motion of the valve with respect to the time of closing; but the indications point to variable requirements in this respect, depending on the resistance offered or the height to which the water is being raised. The action of the machine is smooth and regular when the closing motion is not too abrupt.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of the above company are: Receipts in December, 1887, £21,600; 1st January to 31st December, 1887, £264,480; corresponding months, 1886, £258,600; corresponding months, 1885, £284,720.

AUTOMATIC BILGE CLEANING ARRANGEMENT.

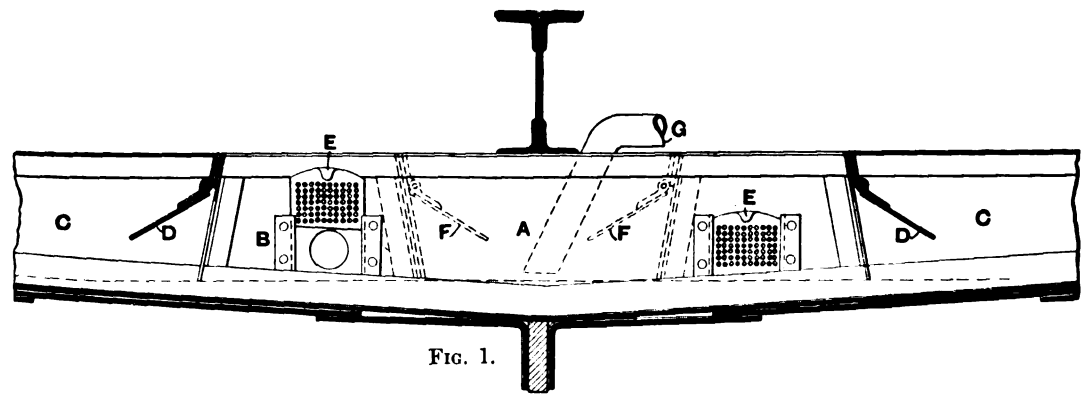

FIG. 1.

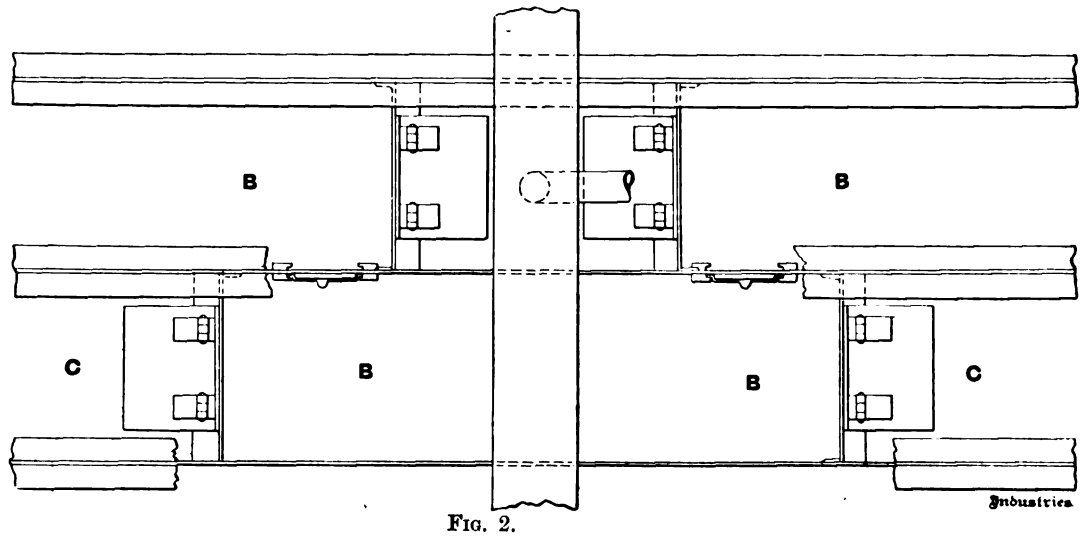

FIG. 2.

AUTOMATIC BILGE CLEANING ARRANGEMENT.

THE practical difficulties experienced in keeping bilge suction pipes clear are by no means small, and choked suction pipes are not a small factor in hastening the sinking of a vessel. Even in the most carefully conducted ship, substances other than water or oil sometimes find their way into the bilges, which, together with the mud deposited from ordinary bilge water, are frequent sources of trouble if not removed before the pumps or the pump suction pipes are choked. The ordinary mud boxes, made of lead, are frequently quite useless. In a recent case, on examining several of the wing suction pipes of a

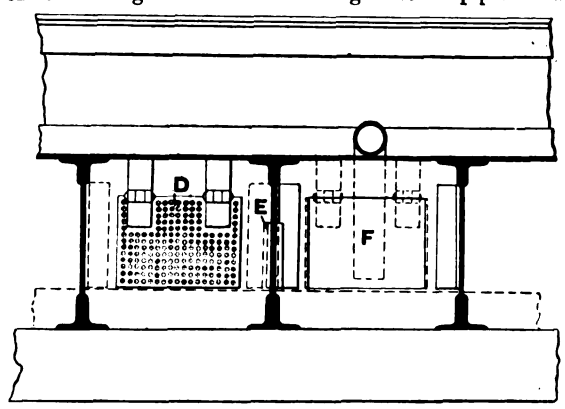

FIG. 3.

steamer, it was found that the mud boxes were rolled into ball shape, their sides having collapsed, thus preventing the water from reaching the suction pipes. The bilge suction pipes of new vessels are frequently liable to get choked, especially when they are hurriedly finished and sent to sea without sufficient interval for close examination and cleaning of all the bilges. A notable instance, of which we have a good recollection, was furnished by a large mail steamer, in which the numerous ordinary engine and boiler bilge suction pipes were choked, and therefore useless. Heavy weather prevailed at the time, and large quantities of water were being shipped. The water rose to the stokehold plates, *i.e.*, to about 6ft. in depth, and but for the presence of mind of those in charge of her, it is doubtful whether the vessel would have completed her passage. It was impossible to clear the mud boxes in time, and temporary suction pipes had to be laid, there being fortunately a number of lengths of ventilating piping available. Many other instances might be mentioned where trouble and danger have been caused by "choked pumps," but it has been sufficiently shown that any improvement in the present mode of fitting strum boxes is worthy of attention. Stephenson's patent automatic bilge cleaning arrangement, which would appear to meet all this difficulty, is illustrated in Figs. 1, 2, and 3. This arrangement is designed for removing automatically all chips of wood, small coal, or other matter which may find its way into bilges, to the wing spaces, from where it can conveniently be removed, and also to form a centre water space automatically confining the bilge water, thereby keeping the ends of the suction pipes covered so long as any water remains in the vessel. Fig. 1 is a transverse section through a portion of the bottom of a vessel fitted with this arrangement. Fig. 2 is a plan looking from above, and Fig. 3 a longitudinal section, and a short explanation of these illustrations will show the advantages claimed for Stephenson's bilge arrangement. A is the suction well, from which through the pipe G the water is drawn to the pump. The rolling of the vessel at sea causes the water, bearing with it such *débris* as may have got into the bilges, to flow through the perforated hanging doors DD, which open automatically outwards towards the more deeply immersed side of the vessel. On the return roll the flap valve automatically closes, preventing the return of the rubbish, but allowing the water to flow freely through the perforations. The water thus cleared then flows through the vertical perforated sliding doors E E into the after frame space, in which the suction well A is situated, and passing through the solid hanging doors F F, which are arranged to swing by the movements of the vessel in the opposite direction to the perforated doors D D, is retained in the centre suction well, thereby enabling the bilges to be pumped dry when the ship is rolling in rough weather, as well as when sailing on an even keel. The ordinary mud and strum boxes are dispensed with, which to some extent compensates for the extra cost of this improved arrangement, so that the difference will not be excessive, while the advantages are manifest. The spaces marked B are only available for water that has passed through the separators D D from the ordinary wings or bilges marked C. Mr. Stephenson submitted his arrangement to the inspection of Mr. B. Martell, Chief Surveyor of Lloyd's Register, and that body approved of its adoption; and during a trial of fifteen months in the s.s. "Ardgay," of Aberdeen, it has given every satisfaction. Messrs. Donkin & Nichol, engineers, St. Andrew's Works, Newcastle-on-Tyne, are the sole makers and licensees for this apparatus.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 10th January, 1888.

The Iron Market.—The higher prices announced last week by the merchants in their New Year's circulars have somewhat checked the course of business. Every observer of the market must have foreseen this effect. I have repeatedly pointed out of late that the brisk buying which has characterised the business in iron for some weeks past, was largely due to a desire on the part of consumers to anticipate the advance which has now taken place. They are, therefore, sufficiently provided with material for some time to come. The lull is, however, not likely to be of long duration, because it is becoming apparent that a further advance must shortly take place. Country buyers are already seeking to cover all their needs in the next three months, in anticipation of this further rise. Many would go to a more distant date, as late in many instances as the end of May; but manufacturers are unwilling, as I stated last week, to bind themselves beyond the first quarter, except at a price considerably above that now prevailing. These are facts which show unmistakably the tendency of trade. Reports received this week from the chief centres of the iron industry are characterised by a cheerful tone. Everywhere there is said to be firmness or an upward movement in prices. The demand steadily increases for nearly all classes of goods, and the prospects for the first half, at least, of the present year are very encouraging. In the Meurthe-et-Moselle several blast furnaces are to be blown in at once, the stocks of pig iron being exhausted, and the demand above the present rate of production. Longwy prices are: 33s. 7d. per ton for forge and 41s. 7d. for foundry pig. The Société des Forges de Denain et Anzin have obtained a contract for 8000 tons of rails for Italy, at the price of £4. 11s. 7d. per ton delivered at Venice.

The Metal Market.—The upward movement in copper continues, the latest official quotation being £88. It is, however, to be borne in mind that these quotations represent nothing more than purely speculative movements. Of genuine business there is now practically none. Consumers are existing upon the stock of metal they have in hand, or failing that, buy only sufficient to meet the most pressing needs of the moment. As evidence of the unreality of the official quotations, it may be stated that genuine purchases of copper for prompt delivery may be effected at a price much below £88. Tin remains unchanged. Lead is a little better; and spelter moves steadily upward. The following table shows the prices of metals at the end of each year since 1880, that is, for a period including the exceptional rate of 1881:—

December 31st..	1881.	1882.	1883.	1884.	1885.	1886.	1887.
	£	£	£	£	£	£	£
Copper (Chili bars)	74·0	69·0	60·6	51·0	44·0	40·0	85·5
Tin (Banca)	118·8	104·0	91·6	82·8	101·6	108·6	170·8
Lead	15·1	13·35	12·0	10·3	11·45	12·45	16·0
Spelter (Silesian).	19·0	13·45	16·1	15·25	16·3	15·4	22·0

The true position of each metal and its stability in the market are shown in the following table, in which the closing prices for the year 1887 are compared with the highest and lowest prices of the last "fluctuation period," and the mean of these extremes:—

	Highest.	Lowest.	Mean.	Present.
	£	£	£	£
Copper	74·0	40·0	57·0	85·5
Tin	118·0	82·8	100·8	170·8
Lead	15·1	10·3	12·7	16·0
Spelter	19·0	13·45	16·22	22·0

Taking into account the greater activity in the consuming industries, the current rates of lead and spelter do not appear exaggerated; but those of copper and tin, particularly the latter, have reached a level which they cannot long occupy, being wholly out of accord with the conditions of the trade.

The Sugar Bounties Conference.—The prospect of the abolition of the sugar bounty system is occasioning some uneasiness among growers, some of whom seem disposed to diminish the acreage under beet cultivation next season; but in well informed circles no importance is attached to the recent conference held in London, which is regarded as merely a diplomatic expedient, the object of which has been already attained. The project, which involves the repeal of the law of 1884, is, in the opinion of many whose position lends weight to their judgment, for the present at least, wholly outside the field of practical politics.

BERLIN, 9th January, 1888.

The Coal Market.—Considerable inconvenience and loss have been caused in the coal market by interruptions of railway and river traffic through the severe weather of the last two months. Especially in Upper Silesia the lines have been blocked by snow, causing delay in delivery. If it be considered that the total yearly output of this district amounts to about sixteen million tons, it will be seen that even a slight disorganisation in the traffic must seriously affect the prosperity of the mines, which even under normal conditions is not very great. According to the report of the Breslau Government Office of Mines, which has just been issued, prices are steadily declining. Whereas, in the first quarter of 1885, the average price of coal at the pit's mouth was slightly over 4s. per ton, in the corresponding period of 1887 it was only 3·84s., and this has further declined in the third quarter to 3·74s, and there seems little hope of higher prices in future.

The Iron Market.—The crude iron market in Upper Silesia is fairly animated, and has been greatly strengthened by the pending negotiations between some of the principal blast furnaces in that district and the rolled iron syndicate, under which the annual supply of 30,000 tons of forge pig would be secured up to the end of 1890. Forge pig averages now from 50s. to 54s., and foundry pig from 55s. to 58s.; bars are readily taken at 140s., and profile iron at 155s. Heavy boiler plates are now quoted at 160s. The activity in rolled iron and steel of a month ago has somewhat diminished, but foundries are well employed. A circular has been issued by a number of leading manufacturers making enamelled and plain ware, in which they announce an increase of 20s. per ton in the price of their goods.

Chemicals.—It appears from the last report of the Elberfeld Chamber of Commerce that the original aniline dyes made in that district are gradually being replaced by the new azo compounds, which are not only more brilliant in colour, but also faster, and are especially suitable for the dyeing of cotton fabrics. Owing to these advantages, the new colours and dyes are in extensive demand, and as the works at Elberfeld control the patents, they may be said to have a monopoly for this branch of the trade. The manufacture of quinine and its compounds is at present not so lucrative a business as it was a few years ago. The average price of quinine, which some years ago was from £6 to £7 per lb., has now fallen to £2 per lb., and even at this low figure the article is a drug in the market. This state of things is partly due to over production, and partly to the discovery of other fever remedies, especially antipyrine, which is now largely used. With a view to improve the state of the market, the two largest quinine factories in Germany, viz., Friedrich Jobst, of Stuttgart, and C. Zimmer, of Frankfort-on-the-Main, have amalgamated under the title of Zimmer & Co.

The Building Trades.—Notwithstanding the unfavourable season there is a strong demand for building materials, and the prospects of cement, brick, and lime kiln owners for the approaching building season are favourable. Large orders for cement, building stone, and lime, at remunerative prices, have already been placed for delivery in 1888 and 1889. In consequence of this increased demand the Stettin Portland Cement Factory is now erecting four new large kilns. The present price for cement, as compared with that in January last year, is 1s. per ton higher, that for lime 6d. per ton higher, and for building bricks 8s. per thousand higher.

Corrugated Iron.—The employment of corrugated iron for roofs, walls, and floors has considerably increased since the new police regulation with regard to fire risks has come into force, and large quantities both of sheets and corrugated girders are now turned out by works in this town. The latter are extensively used for floors in factories and mills, whilst a special kind of corrugated sheet is used in the construction of fire proof stairs for dwelling houses. One large building in Berlin—the Circus Krembner—has been entirely constructed of iron, the walls and roof being formed of corrugated sheets.

Asphalt.—Although the experiments made with Professor Dietrich's patent asphalt paving in Berlin, in which the raw material obtained from the deposits in Vorwohl and Zimmer (province of Hanover) were employed, have not proved perfectly successful, the use of this asphalt as a filling for granite and wood paving is rapidly extending. This asphalt, mixed with powdered limestone, has also recently been introduced in buildings for preventing the walls from becoming damp. When the foundation walls have reached the ground level a layer of asphalt, in the form of thin rolled sheets, is applied, and the walls of the building are erected upon this layer, which is perfectly impervious to moisture. The demand for asphalt for various purposes is thus on the increase. To obtain a larger supply, the Egestorff works are now prospecting for new deposits in the neighbourhood of Hanover, and several new shafts are being sunk.

VIENNA, 9th January, 1888.

The Iron Market.—The first result of the new syndicate is a slight increase in the price of bar and profile iron and joists announced by the Prague sales bureau. The increase amounts to about 4s. per ton, making the base price for merchant bars 176s., and for joists 190s. at the works. The Alpine iron works announce that they do not intend to increase their prices, but prefer to await the condition of the market in the spring before making any alterations in their lists. The syndicate affects only the usual kinds of manufactured iron and steel in the market, but not some specialties which are only manufactured by a few works, or which are already covered by previous conventions. To the latter category belong rails, tyres, heavy plates for bridge building, and fine plates. The total production of manufactured iron and steel which comes under the syndicate's rules amounted last year to only 210,000 tons, and the quantity was divided between the syndicated works, according to a schedule drawn up in May, 1886. This, as I have already stated, has now been slightly amended, and the following is a list of the works and their limits of output, based upon the supposition that the trade during 1888 will be the same as that during last year:—

Name of Works.	Quantity In Tons.	Percentage.
Bohemian and Moravian group...	115,400	55·2
Alpine Company	43,500	20·8
Tetschen	19,300	9·2
Ternitz	9,700	4·6
Seven smaller works	21,300	10·2

It will be seen from this table that more than one-half of the total production falls to the Bohemian and Moravian group of iron works. These works, it may be mentioned, were the first to agitate for syndicating the trade in the beginning of 1886, and they have thus secured a leading position. The group consists of the Prager Eisenindustrie Gesellschaft, the Teplitz rolling mill, the Böhmische Montangesellschaft, the Witkowitz works, and several smaller establishments. In the schedule of production the Alpine company occupies the second position, their production being considerably below that of the former group; but the schedule is not a correct index of the quantity of work turned out by the Alpine Company, since their products consist in a great part of such manufactured iron and steel as is excluded from the operations of the syndicate. This company manufactured last year 46,000 tons of cast steel rails, tyres, boilers, bridges, fine plates, and French nails, so that their total production amounted to nearly 90,000 tons. On Saturday last tenders were received by the Kaiser Ferdinand's Nordbahn for the supply of 5200 tons of steel rails and about 2000 tons of accessories, such as fish plates, chairs, bolts, nails, switches, &c. The general condition of the iron market in Austria-Hungary has slightly improved, and in Hungary especially a firmer tone prevails. The Hungarian small arms factory is being financed by the Union Bank of Vienna and Messrs. Loewe & Co. of Berlin. It is now intended to establish this concern on a somewhat larger basis than that of the original project, so that the factory will be in a position to supply not only the requirements of the Hungarian army, but also those of other sections of the Austrian army.

Textiles in 1887.—The condition of the textile industries throughout this country has not been very prosperous during the past year, the quantity of textile goods produced being hardly up to the average of former years, whilst prices have been slightly lower. There was greater activity in those works which supply underclothing for the army; but private consumers during the whole year evinced a reluctance to enter into large transactions, which was undoubtedly due to the uncertainty of the political situation. Cloth mills and clothing factories have greatly suffered from the effects of the Roumanian Customs tariff, and their exports to that country, which formerly were considerable, have almost entirely ceased. The exports of silk and woollen materials to Germany, which also used to be flourishing in former years, fell off considerably during 1887. Spinning mills and cotton printing works during last year produced rather more than was justified by the requirements of the trade, and are now suffering from a glut in the market; but bleaching and dye works are in a satisfactory position. The demand for tricots and worsted goods has been fairly good, though not exceeding the average of former years.

BRUSSELS, 10th January, 1888.

The Coal Market.—Unscreened coal is quoted at 10s. 5d., nuts at 14s. 5d. to 15s. 2d., and in consequence of the increased demand coke is selling above its normal rate. It is probable, therefore, that there will be a rise in the price of small coking coal, especially as there is a prospect of blowing in more furnaces in the Northern district. On the whole, Belgian colliery owners have not much cause of complaint respecting last year, the latter months of which showed very favourable signs. The present year also promises well. There is more business being done in the coal market at present than at the same time last year. Owing to the improved condition of the iron trade, orders have largely increased for coal for rolling mills, &c. During the past year prices have risen from 5d. to 7d. per ton.

The Metal Market.—Prices continue high, though there have been some fluctuations; tin is quoted at £162 to £164, copper ingots at £88, spelter at £21, lead at £16, and regulus of antimony at £50. Foundry pig is firm. Higher offers have been made for the Rumelange furnaces, which passed, as I have already reported, provisionally into the hands of the Crédit Général of Liège and the Bank of Liège. There are several competitors for the purchase, the furnaces being well worked, and having proved profitable hitherto. There is a good demand for girders, sheets, and angle iron at firm prices. Railway waggon builders are well supplied with work; orders for 172 mail vans will be divided among various firms, including Eveard and the Société de Construction of Malines. In order to improve the engineering trades, the State railways will shortly proceed to give out contracts for the extension of Charleroi station. There will be required for the economic railways 326 trucks and 167 passenger coaches. Producers of raw iron are uniting with the owners of rolling mills in asking for the abolition of the Customs duty on foundry pig, on condition that they receive from the State railways a reduction of the rates on iron ore. Most of the ore is imported from the Grand Duchy of Luxemburg, and heavy rates are paid to Charleroi and Liège, which, in effect, are equivalent to an import duty.

FLAX AND YARN MARKETS.—The flax markets this week exhibit more distinctly the tendency to weakness which appeared towards the middle of December. This is no doubt partly due to the influences of the season; but apart from these, buyers show hesitation and reluctance to deal largely. This reluctance arises mainly from the high prices asked by sellers. The best qualities, however, are eagerly bought up. A slight reduction of the current rates for the medium qualities would probably bring much greater activity, especially as it is now known that Russian flax is greatly inferior to last year's stocks. In view of the general complaints of the quality of Russian flax of 1887, it is surprising that it holds its position so firmly in the market. There is not much doing in yarns, but a better demand is expected towards the end of the current month.

ELECTRIC LIGHTING.—The Thomson-Houston Company has bought some ground in the Champ de Mars for the installation of steam engines and dynamos for lighting the Théâtre Molière. This company has also arranged with M. Meunig to light in the district of Ixelles, in which the theatre is situated, the Porte de Namur, the Théâtre Café, and part of the Chaussée de Wavre. A proposal has also been made to the local authorities to light the whole quarter electrically instead of by gas, but the offer has not been accepted. Electric lighting is making rapid headway, especially in Brussels, and among those who have lately adopted it are several cafés in the centre of the town, and the Foire de Leipzig emporiums. A syndicate is spoken of to promote the adoption of electric lighting, which will include Messrs. Mourlon, Gérard, & Co., and the Société Industrielle d'Electricité.

DÜSSELDORF, 9TH JANUARY, 1888.

THE COAL MARKET.—There is still great activity in the coal market. The demand for household coal has been increased by the cold weather of the last three weeks. The industrial qualities are much sought after. Coking coal and coke are rising in price. The following are the prices current in December, the figures in brackets being those for January of 1887: Gas coal, 7s. 1d. (7s. 2d.); household coal, unscreened, 5s. 9d. (5s. 7d.); round, 7s. 5d. (7s. 7d.); large washed "nuts," 8s. 3d. (8s.); medium, 7s. 10d. (7s. 6d.); small, 6s. 1d. (5s. 8d.); industrial qualities, unscreened, 5s. 1d. (4s. 10d.); round, 9s. 9d. (8s. 3d.); "nuts," 13s. 9d. (10s. 3d.); small, 2s. 6d. (2s.); coking coal, 4s. 7d. (3s. 8d.); foundry coke, 9s. 9d. (7s. 10d.); blast furnace coke, 8s. 4d. (7s. 2d.). The stability of the gas coal prices is due to the syndicate which controls the business of the gas coal mines.

THE IRON MARKET.—The last advance in the prices of pig iron declared by the crude iron syndicate has occasioned some uneasiness in the market. Makers of finished iron and steel have taken the alarm, and protest against the new rates on the ground that the state of the trade will not allow them to follow the movement. This circumstance would seem to indicate that we have now reached the highest limits of prices for crude iron. Some classes of finished produce will probably go a little higher; plates especially are likely to advance. There is not yet that animation in the markets which prevailed down to the end of the third week in December, but the influence of the holiday season is not yet wholly at an end. Progress is being made with the organisation of the sheet iron syndicate. The firms of Hender, Schlüter, & Vollrath, of this town, Franz Bicheroux & Sons, of Duisburg, Thyssen & Co., of Mulheim, and Felder & Co., of Kalk, have joined it provisionally for the first quarter of the current year. The Chain Makers' Association is seeking to fix for the whole of Germany a kind of sliding scale of prices dependent upon that of wire. The enhanced prices of iron goods and the dulness of the American markets have told unfavourably upon the export trade of the last three months of the year. I take from the Customs returns the following statistics of the exports down to the end of November, 1887, the quantities for the corresponding period of the preceding year being, for easy comparison, given within brackets. Pig iron, 194,387 (228,461) tons; scrap iron, 55,330 (47,504) tons; half finished iron and steel, blooms, puddle bars, and ingots, 37,080 (37,936) tons; finished iron and steel, bars, angles, and plates, 267,153 (229,147) tons; wire, 224,074 (217,464) tons; rails, 161,101 (146,271) tons; other railway iron, 38,488 (32,567) tons; manufactured goods, other than machines, 176,426 (160,604) tons. Total iron of all kinds, 1,154,039 (1,099,954) tons. The increase compared with 1886 is but 5 per cent., against 8 per cent. at the end of the third quarter. The skrinkage is chiefly visible in pig iron and wire.

LILLE, 10TH JANUARY, 1888.

TEXTILE MANUFACTURES.—Business in textile goods has been very quiet this week. Buyers, attracted from the markets by the Christmas and New Year's festivities, have not yet returned, and manufacturers are busy with their accounts; but next week a resumption of business may be expected. In the meantime, there is little that calls for remark. The tone of business generally is hopeful. At Roubaix the outlook for the woollen trade is very encouraging. In spite of the approaching sales of wool in London, announced for the 31st inst., the prices of the raw material remain firm. The cold weather has caused a brisk demand for hosiery, which has served to greatly strengthen the market for South American wool. The year begins under the best auspices, the commercial situation being healthy and strong, and the prospects of trade generally are encouraging.

THE FLAX AND YARN MARKETS.—Though the influence of the holiday season is still felt, there is considerable animation in the market for flax. The demand is strong for home grown produce, particularly Walloon from Douai and Bergues, and prices are very firm. Russian flax is much sought after. Dealings this week, though below the exceptional figures of the last fortnight, have been numerous and important, and prices show a tendency to improve. The situation continues to improve for yarns. The demand grows steadily, and spinners have been able to obtain another advance in prices. The medium and fine numbers are most sought after. In tows the situation remains unchanged, dealings being limited to the needs of the moment. A large amount of business is being done in jute, at constantly advancing rates.

THE IRON MARKET.—The present aspect of the iron market contrasts favourably with that which existed two months ago. In the place of doubt, hesitation, and languor, we have now confidence, eagerness, and animation. Orders come to hand freely. Merchants seek to contract six months forward; but, as I stated last week, manufacturers refuse to sell further forward than the end of March, except at a considerable advance on current rates. These rates are: £5 to £5. 4s. for bars; £4. 16s. to £5 for joists; and £6. 4s. to £6. 8s. for common plates. The latter are in strong demand at these prices. The advance is now fully secured, and the prospects are favourable to further progress.

FREE IMPORTATION OF SACKS.—A matter of considerable importance to the jute manufacturing industry of this district, and to the importers of grain, is just now being debated with some acrimony. Since the enactment of the English law prohibiting the shipment of grain in bulk, a large number of sacks annually enter France duty free. These sacks, which are practically new, having been but once used, are sold in the markets here, to the injury—it is said to the almost total destruction—of the native trade in those goods. The jute manufacturers are bringing pressure to bear on the Government to put an end to the anomaly by declaring these sacks liable to the ordinary duty. As the Minister of Commerce has shown himself to be favourably disposed towards the request of the manufacturers in this matter, it will probably be granted.

AMSTERDAM, 10TH JANUARY, 1888.

ART INDUSTRY EXHIBITION AT THE HAGUE.—A National Art Industry Exhibiton is to be opened this summer at the Hague, for which the Netherland Government have asked the States General a small subsidy. It is to consist of a main building in an ornamental style, surrounded by gardens, in which will be situated the various offices, restaurants, bars, &c. The gardens will be laid out by the Botanical Society of the Hague. The local executive committee of the Exhibition is a strong one. Mr. A. W. Stortenbeker is the architect.

RAILWAY CONSTRUCTION.—It has been officially announced that the proposed State railway from Rotterdam, along the new water way, to the seaboard at the Heck van Holland, which was mentioned a few weeks ago in *Industries*, will probably be finished by the end of 1889. This seems a rather long time, but the Government explain that the difficulties of construction have been underrated, and the soil between Schiedam and Vlaardingen has been found to be very marshy.

STEAM TRAMWAYS.—A Dutch-Belgian syndicate has been formed to buy up existing Dutch steam tramways and construct others in different parts of Holland. The first new line will be laid from Haarlem to Alkmaar in North Holland; a concession for this has already been granted by the Government to Mr. J. Holland, of Amsterdam, a member of the syndicate.

WINTERTHUR, 9TH JANUARY, 1888.

NEW INDUSTRIES.—Switzerland has frequently shown that she can rapidly develop any new industries which may be introduced into the country. Examples have been seen in the chemical industry, textiles (especially embroideries), and preserved provisions. The Customs returns are now being examined, with a view to ascertain what other new manufactures there may be room for. It appears that in 1886 there was imported sugar to the value of £560,000, which paid £110,352 duty. These facts have led to the establishment of a beetroot sugar factory at Hochdorf, Lucerne. Raw sugar only will be made, and operations will be to the extent of 1200 tons per year. This will also give an impetus to the Swiss agricultural interest.

UTILISATION OF WATER POWER.—Switzerland pays Germany annually for coals a sum of about £500,000, although hundreds of thousands horse power in rivers and streams are running to waste. With the progress of electrical science, something is now being done in the direction of utilising these forces, and two projects are now under consideration. The first of these is in connection with the Goldach water works, now supplying water to the town of St. Gall, and it is proposed to add a power plant to this works. For this purpose it would be necessary to build a reservoir of 26,700 tons capacity, so as to obtain constant water power, which would by means of dynamos be converted on the spot into electrical energy representing 315 h.p. Of this 250h.p. would be sent to St. Gall for lighting purposes, and 65 h.p. for working motors. The total cost of the installation is estimated at a little over £16,000, and allowing for a sufficiently low rental for the lamps, in order to be able to compete against the reduced price of gas which the promoters consider will necessarily follow the introduction of the electric light, they estimate that the net profit on the capital invested will be 13 per cent. The other proposal refers to the river Limmat, which is to be dammed up between Zurich and Baden by a weir, so as to obtain an available head of from 26ft. to 28ft. The influence of the weir would be felt for only about two and a half miles up the river. During the last ten years the minimum quantity of water passing from the lake of Zurich into the Limmat was 20 tons per second. This occurred in the exceptionally cold winter of 1879-80. At all other times the quantity was greater, but taking 20 tons as the minimum available, the promoters of this scheme estimate that 1600 actual horse power could be obtained from turbines placed close to the weir. This power would be converted into electrical energy, and then transmitted for lighting and motor purposes.

MADRID, 9TH JANUARY, 1888.

NEW MINES.—Since the rise in metals there has been a great movement in the mining market, and I have examined a number of schemes for the promotion of new copper mines. Many of these appear to be doubtful speculations, whatever the price of copper might be; but some should prove remunerative, if copper keeps above £70 per ton. There are some cases also in which the mines could be worked at a profit if prices were even lower, provided lines of railway were built at once. Lead and silver mines are also projected; in some cases these are old ones which have been closed owing to low prices. There are also antimony mines being offered. The Vielle Montagne Company and the Real Compania Asturiana are the only buyers on the spot for zinc ores, and, consequently, have command over prices and conditions.

THE NAVY.—The official announcement of the Government that they are prepared to consider offers for the building of three cruisers of 6500 to 7000 tons, of the aggregate value of £1,440,000, has caused much interest in industrial circles. It is stipulated that they are to be built in Spain and with Spanish materials. Spanish firms are to have the preference; but failing these, the order will be given to foreign firms, provided they engage to establish yards in Spain. It is possible that the order will fall into the hands of the Marquis of Mudela, whose establishment at Bilbao is managed by Mr. Martinez de las Rivas. There are at present only four blast furnaces at these works, but all the plant necessary for turning out the largest men-of-war is to be erected.

NEW YORK, 31ST DECEMBER, 1887.

COAL.—For the present year the coal production has been 31,000,000 tons, an increase of 2,390,000 tons over last year. In spite of this increase, coal is very scarce in Kansas and other parts of the West, and in Philadelphia a short time ago a coal famine seemed almost inevitable. About 1000 men in Philadelphia and 1500 in Elizabethport have been discharged by the Reading Railroad, and it is feared that it will cause a suspension of production throughout the entire Pennsylvania coal fields.

IRON AND STEEL.—The production of iron and steel for the past week has been better than for the corresponding week of 1886. There have been 341 furnaces in blast, having a total capacity of 142,000 tons weekly; and 246 out of blast, having a capacity of 59,000 tons. The weekly production is about 2000 tons less than a month ago, but about 18,000 tons better than for 1886. The amount of iron and steel imported from England during the first eleven months of the current year was 1,211,000 tons, against 725,000 tons for 1886, an increase of 67 per cent.; and the imports consisted chiefly of pig iron, unwrought steel, and tin plate. The Johnson Steel Street Railway Company lately purchased two hundred acres, for the purpose of erecting a rolling mill and steel plant. They have, however, partly abandoned their plan, and for the present intend only erecting a rolling mill. The building will be 350ft. by 150ft., and will be used for rolling their patent steel street rails. The mill will be in working order about next May, and will have a daily capacity of about 300 tons. During the past week 40,000 tons of steel rails have been contracted for, at prices varying from £6. 4s. to £6. 8s., averaging slightly lower than last week. Bar iron is weaker and the demand is less, not only in crude, but in many forms of manufactured iron and steel.

METALS.—The corner in lead, copper, and tin has had little effect in increasing prices during the last week, except in the case of tin. There is comparatively little dealing in copper, the price having declined one-fifth cent per lb., the quotation to-day being 17·9 cents, against 10 cents three months ago. Lead has declined one-fifteenth cent, and the boom in prices may be said to be over. Tin has advanced 1 cent, and prices seem fair to hold for a little time longer. One of the causes assisting speculation in keeping up the price of copper is the Calumet and Hecla fire, which is not yet extinguished. The experiment of using carbonic acid gas to check the fire has not been very successful. The gas was manufactured at the mine, and sent to a depth of 500ft. through a 4in. pipe. At first it seemed to have the desired effect, for on November 25th, at the mouth of a shaft 1700ft. above the fire, the temperature had been reduced from 128°F. to 88°F.; but later telegrams show that the method was not so efficient as it at first appeared.

ENGINEERING PROGRESS IN 1887.

In his Presidential Address to Section G of the British Association, last year, Prof. Osborne Reynolds remarked that the completion of the Tay Bridge, the Severn Tunnel, the progress of the Forth Bridge, and the commencement of the Manchester Ship Canal in one year and in one country are sufficient assurance that as yet there is no lack of enterprise or sign of falling off in heroic undertakings. The first of these works, the Tay Bridge, is over two miles long, and occupied only five years in construction, and it was described in these pages at the time of its completion (see *Industries*, Vol. II., page 525), the engineers being Messrs. Barlow & Son, of London, and the contractors Messrs. W. Arrol & Co., of Glasgow. The fatal experience of the previous bridge, the varying bed of the Tay, the rapid current, the exposed situation, and the great length of the bridge, all rendered the work of designing and constructing it one of unusual anxiety and difficulty. Fortunately, the conditions of the case rendered it unnecessary that any unusual type of bridge should be designed, and the engineers wisely confined themselves to ordinary piers and girders of sufficient stability and strength. There are in all eighty-five spans, in lengths ranging from 50ft. to 245ft., and the greatest height above high water mark is 107ft.; the height in the centre or navigable spans is 79ft., which affords a headway of say 77ft. The bridge was successfully opened in June last, after having been thoroughly tested, and is an example of good design and workmanship in every respect.

The Severn Tunnel was really completed at the end of 1886; but as a description of it appeared in our pages (see *Industries*, Vol. III., page 289) during the past year, it may briefly be referred to. The inconvenience caused to traffic between Bristol and the towns of South Wales had long been felt, and so far back as 1871 plans were deposited for the tunnel which has since been constructed, and is four and a half miles long, the thickness of rock at the crown of the arch varying from 15ft. to 30ft. Great difficulties and consequent delays were experienced in its construction, and it was not until 22nd November, 1886, that the line was inspected on behalf of the Board of Trade, and it was opened for passenger traffic on 1st December, and since that time not the slightest hitch has occurred in its working.

During the year good progress has continued to be made on the Forth Bridge, of which Sir John Fowler and Mr. B. Baker are the engineers, and has been duly reported in these pages (see *Industries*, Vol. II., pages 4, 358; Vol. III., pages 15, 289, 454, 618). Professor Reynolds, in the address above mentioned, said the Forth Bridge was a structure the very thought of which causes those who have seen the place to hold their breaths, and of which the relative size may be best realised from the fact that, held out in arms an eighth of a mile long, at a height of 200ft. above the sea, as a mother might hold an infant, are structures no less than the single spans of the Britannia Bridge. Not only is the bridge distinguished by its design, but the methods of construction are novel. We would especially refer to the bold expedient of discarding any form of fixed scaffolding, and utilising the completed portions of the bridge as a base for carrying on the work. Moreover, the many interesting and ingenious machines and processes employed in manipulating the materials, due in great part to the fertile ingenuity of Mr. William Arrol, one of the contractors, some of which he described in a paper read before the Institution of Mechanical Engineers, seem in themselves to open up a new era in mechanical engineering. The various papers by Mr. Baker, Mr. Biggart, Mr. Wood, and others who are engaged on the work, are well worthy of study by all concerned in engineering. The masonry consists of Aberdeen granite and Arbroath stone, and the superstructure is entirely of steel. The design and construction have been criticised in various respects, but neither the engineers nor the contractors have any doubt of either their theory or their practice; and so far as we have been able to judge, their confidence seems to be well justified.

In the department of Civil Engineering, the most important event in the United Kingdom during the past year was without doubt the successful commencement of the Manchester Ship Canal. We have given a preliminary description and some general information regarding this great work, and we intend to keep our readers informed of its progress; but in the meantime it is sufficient to refer to the paper on it read by Mr. Leader Williams before the British Association (see *Industries*, Vol. III., page 337). Like many other great undertakings, this Ship Canal has not been by any means a sudden thought, but for many years has been in the minds of those interested in the prosperity of Manchester, and it affords another example of what may be accomplished by energy, perseverance, and pluck. So far back as 1825 an application was made to Parliament for power to construct a ship canal to the mouth of the Dee, Mr. Rennie being the engineer; but the attempt was unsuccessful. In 1840 it was proposed to render the Mersey and Irwell Navigation available for sea-going vessels, and later on other suggestions were made; but it was not till 1882 that the proposals for the Canal which is now being constructed took definite shape, and the prospectus of the Manchester Tidal Navigation Company issued to the public; Mr. Daniel Adamson being the moving spirit in the matter at the time. To Mr. Williams' paper we must refer for an account of some of the engineering problems involved, and to the parliamentary records for the legislative difficulties which had to be overcome. The expenditure of money in passing such a Bill as that required for the Manchester Ship Canal is a disgrace to our legislative system, and it is probable that the reform of that system may be hastened by the experience of the promoters of the Bill. The work of constructing the Canal has now been fairly inaugurated, and, in fact, the progress made, although bearing an infinitesimal proportion to the whole project, is yet sufficient to show the great magnitude of the undertaking. At the Manchester end work has been commenced, and at various points on the line ground has been broken. Steam navvies, dredgers, and all the most improved appliances are to be employed. If the same energy is continued during the work as has been displayed at its beginning, we have no doubt it will be completed in the time specified, that is, in four years. The Clyde, the Tyne, the Tees, and the Thames all show the importance of water ways for the development of industries and trade along their banks, and there can be no doubt that when the Ship Canal has been completed, and increased facilities given for shipping and carriage, it will add immensely to the trade and industry of Manchester.

The only great foreign engineering work in which we have much interest is the Panama Canal, for if it were successfully accomplished it would mean the revolutionising of a considerable part of our foreign commerce, the creation of a new branch of international politics, and a large number of diplomatic problems. We are now within a year of the time when M. de Lesseps promised that the Canal would be opened, and we believe that he still keeps to that date. But very serious financial difficulties are now beginning to appear, and M. de Lesseps has practically confessed that the future of the enterprise is in the hands of the French Government, and has pointed out that its failure would be a crushing national disaster, and having exhausted all means for raising funds, he asks for Government assistance. The great difficulty is to know what to believe regarding the progress the works have made. We are afraid that M. de Lesseps has either deceived himself or has been deceived upon this point. Various independent reports have shown this, and the latest which have been published confirm it. The United States of Columbia sent a special official to examine the works and report upon them, and he says that the reports which have been presented to the shareholders have been partial in their character and do not furnish an exact idea of the situation, and further, that they have greatly exaggerated the number of men employed. Instead of 15,000, as stated, not more than 5000 ever seem to have been employed, and the work performed seems to confirm this estimate. We shall observe with interest the developments of the next few months, for affairs have now reached a crisis, and we trust that some means will be found for completing the great work, although it must be confessed that its prospects are not by any means bright.

In the departments of Mechanical Engineering and Shipbuilding there has been no striking discovery or improvement, although there has been a considerable development on recent lines. This is especially the case in marine engineering, steel gradually replacing iron in construction, and the steam pressures used are becoming higher. Ordinary two-cylinder compound engines are being replaced with triple and quadruple expansion engines, not only in merchant but also in warships. Among the former the most improved designs are always to be found in the Atlantic steamers, as the great competition in that trade forces shipowners to take hold of everything which leads to economy. During the past year, however, only one important steamer has been added to the Atlantic fleet, the s.s. "Lahn," built by the Fairfield Company, of Govan, for the Norddeutscher Lloyd's Company, Bremen, of 5500 tons. Her engines are of the triple expansion type. There are five cylinders, inverted, with three cranks. The two high pressure cylinders are each 32½in. in diameter, the intermediate is 68in. in diameter, while the two low pressure cylinders are each 85in. in diameter, and the stroke is 6ft. The indicated horse power is 9500, that of the "Umbria" and "Etruria" being over 14,000; the "Servia," 10,300; and the "City of Rome," 11,890. None of these latter, however, have triple expansion engines, and consequently the speed attained is by a greater expenditure of fuel. The "Lahn," when on trial on the measured mile on the Clyde, steamed 19·46 knots, and maintained 18¾ knots per hour in a six hours' run. She has not yet crossed the Atlantic; but when she does her sailings will be watched with interest, although she is not intended to beat the "Umbria" and the "Etruria." Two British companies, however, are arranging to attempt this, viz., the Inman and International Company and the White Star Company, each of which is building a couple of vessels for the purpose. As these may be taken to represent the latest developments of merchant steamships, a short description of the former of these, now being built by Messrs. J. & G. Thomson, of Clydebank, may be given. They are 525ft. long on the water line, or 560ft. over all; 63½ft. beam, and 42ft. moulded depth; and their gross tonnage 10,000 tons. They have four complete decks, promenade (upper, main, and lower), with partial deck above promenade deck and partial deck below the lower deck. Speed has not been sacrificed to safety, and in addition to being minutely sub-divided these vessels have been so arranged that no bulkhead has a door below the level of the upper deck, for it was felt by the designers that only in this way can the benefits of minute sub-division be insured; because if, in an emergency such as happened in the "Oregon," the safety of the vessel depends on shutting water tight doors, the safeguard may vanish just at the time it is required. Moreover, the vessels are being fitted with two sets of engines, each driving a separate screw, and placed in separate water tight compartments, and the boilers are in three separate compartments completely cut off from each other. While, therefore, the vessels are well provided against collision, they are also very much better able to avoid collision by having two sets of machinery, one of which may be readily reversed, while the other is going ahead. They are fitted with double bottoms, having each a capacity of 1500 tons of water, which weight is available for purposes of immersion or stability at the wish of their commanders, while the double bottoms are a precaution against injury by grounding. The machinery is of the most improved type, the engines being triple expansion, and the boilers having forced draught on the closed stokehold system. The space occupied has thus been very much reduced, and consequently that available for passengers and cargo much increased. The vessels are fitted throughout with Messrs. Brown's hydraulic appliances for the dispatch or shipment of cargo or coals, for reversing the engines, and for steering, while the comfort and convenience of passengers have been attended to in every respect. Lastly, the ships have been specially arranged as armed cruisers, in which capacity their high speed, improved sub-division, and good turning power all render them highly capable of doing great service.

The steamers built for the Indian, Australian, and Channel trades have all been marked by a development in design and construction very much on the lines indicated above. Messrs. Napier, of Glasgow, have built the "Damascus" for the owners of the well known "Aberdeen," which may be looked upon as the pioneer triple expansion engine vessel, and have taken full advantage of the experience gained in the interval. Messrs. Denny, of Dumbarton, have built a vessel of 5000 tons, fitted with quadruple expansion engines. The Channel service is beginning to be as exciting as the Atlantic, some of the vessels added having great speed. The Fairfield Company, of Govan, have launched four paddle steamers. Two of those—the "Victoria" and "Empress"—run regularly from Dover to Calais, a distance of twenty-one miles, in a little less than an hour; while the other two—the "Victoria" and the "Prince of Wales," the Manx boats—when on trial on the Clyde, were driven from 22 to 23 knots per hour. Our space will not allow us to enter into particulars regarding other merchant vessels; but what we have given will be sufficient to show the type which is now being developed. It may be interesting, however, to note the increasing use of steel in shipbuilding. Of the 326 ships built in 1887 on the Clyde, 194, representing 148,596 tons, were constructed of steel, leaving only 46 vessels, of 36,286 tons, of iron, and these latter are almost entirely sailing ships. The increasing use of steel may be gathered from the following table, which shows the percentage of steel to total tonnage since 1879:—

	Total tonnage.	Tonnage of steel vessels.	Percentage of steel to total tonnage.
1879	174,750	18,000	10¼
1880	241,114	42,000	17½
1881	341,022	66,609	19½
1882	391,934	108,254	27⅔
1883	419,664	129,651	31
1884	296,854	133,670	45
1885	193,458	92,677	48
1886	172,440	116,932	68½
1887	185,362	148,596	80

In warships the triple expansion engine has now been adopted. Messrs. Napier & Sons, of Glasgow, have sent out large engines of this type for Russian men of war. The "Reina Regente," a protective deck cruiser of 5000 tons, built for the Spanish Government by Messrs. J. & G. Thomson, of Clydebank, depends for its safety from shot, not on a belt, but partly on a steel deck and partly on a minute sub-division of the structure, there being in all 143 compartments, most of which are in the vicinity of the water line. For a justification of this method of construction, reference must be made to a paper recently read by Mr. Biles before the Institution of Naval Architects, in which he produced data to show that the weight

Digitized by Google

of a protective deck cruiser was so much less than that of a belted cruiser, that sufficiency of power could be added to the engines to secure one and a half knots more speed per hour. The Admiralty designers have evidently appreciated some of the good qualities of the "Reina Regente" design, and have ordered some cruisers on the same general principle. On the Tyne the most noteworthy warship that was built during the year was H.M.S. "Victoria," of 6000 tons total tonnage, with engines of no less than 12,000 h.p., and which we described at the time it was launched (see *Industries*, Vol. III., page 53), the builders being Messrs. Sir W. G. Armstrong, Mitchell, & Co. The other vessels produced by the same firm for war purposes were three revenue cruisers of small tonnage for the Chinese Government, and a hopper gunboat for the Admiralty. The Palmer's Shipbuilding and Iron Company built the cruisers "Orlando" and the "Undaunted," two of the five belted cruisers ordered by the Admiralty. The engines were horizontal triple expansion, and are good specimens of design and workmanship, and promise to maintain the high reputation of the firm.

In the department of General Mechanical Engineering there has been no very striking invention or development, and we must content ourselves with referring to our reports of the Manchester Exhibition for examples of good practice. That Exhibition will long be remembered as one of the most successful ever held, and its machinery department was most complete and worthy of attentive study.

In the department of Mining we so recently gave an account of "Fifty Years' Scientific Progress in Coal Mining" (see *Industries*, Vol. III., pages 535, 584), that it is unnecessary to enter on that part of the subject; but as bearing on the position of the coal trade throughout the world, the following statistics, which are the most recent available, will be of interest as showing the production of coal, the official value of the same, and the average value per ton in 1886:—

Statement showing the quantities of coal raised in different Countries or States, the number of employés engaged therein, and the average quantity of coal raised per employé per annum:—

	Production. Tons.	Value. £	Average price per ton. s. d.
United Kingdom....	157,518,482	38,145,930	4 10½
United States	96,055,000	29,422,400	6 1½
Illinois (only)	10,279,000	2,230,000	4 4
Germany	58,056,598	15,036,384	5 2
France	19,527,120	9,605,900	8 10
Belgium	17,285,533	5,701,680	6 7

	Tons raised.	Hands employed.	Average output per employé per annum.
United Kingdom...	157,518,482	519,970	302
United States.....	96,055,000	No returns.	—
Illinois (only)	10,278,890	26,804	383
Germany	58,056,598	217,581	266
France.....	19,527,000	109,426	178
Belgium	18,041,000	105,182	171

These figures are important in view of the new Act for the regulations of coal mines. We still produce on an average the best and cheapest coals, but in cheapness of production we are run pretty closely by Germany. The average cost of our coal is 4s. 10½d. per ton, and of German 5s. 2d.; but in 1872 and before that, German coal cost about 11s. In view of the restrictions of the new Act we must take care that we do not exclude ourselves from foreign markets.

During the past year a great amount of discussion has taken place on the subject of Technical Education, and considerable developments have been made in many of the institutions designed to afford a training in the theories of the various industries and arts. A Technical Schools Bill was passed for Scotland during the last session of Parliament, although that for England was withdrawn. Both of these measures were very imperfect, and in its present shape the Scotch Act is not likely to have much effect until, at least, public opinion has been educated in the matter. In order to assist in guiding this opinion in the proper direction, the National Association for the Promotion of Technical Education, with the Marquis of Hartington as president, has been founded, and it promises to be of great utility. No one can doubt that if attention be paid to education, and if the education be of the proper kind, containing as it should a due admixture of theoretical and practical training, we shall be able not only to maintain our present position, but to outstrip our neighbours, who for some years have been rapidly making up on us in those departments requiring scientific knowledge. In all the main departments of engineering, the record we have given above shows that we are still able to hold a prominent position in the industrial progress of the world.

STARCH.—Large quantities of starch are at present imported into Switzerland, principally from Germany; but a maize starch factory has now been started at Mels by Messrs. Oskar Neher & Co. This new establishment will be of importance to our textile industries, as maize starch is coming into greater favour than wheat and rice starch.

Notices of Meetings.

THIS WEEK.

INSTITUTION OF CIVIL ENGINEERS.—Friday, 13th January, 7-30 p.m. Students' meeting. Paper to be read on "Railway Engineering in British North America," by Mr. Robert J. Money, Stud.Inst.C.E.

NEXT WEEK.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 17th January, 8 p.m. Ordinary meeting. Paper to be further discussed: "The Use and Testing of Open Hearth Steel for Boiler Making," by the late Mr. Hamilton Goodall, A.M.Inst.C.E. Paper to be read, time permitting, "The Erection of the Jubilee Bridge over the River Hooghly, on the line of the East Indian Railway," by Sir Bradford Leslie, K.C.I.E., M.Inst.C.E.

SOCIETY OF ARTS.—Tuesday, 17th January, 8 p.m. Foreign and Colonial Section. Paper to be read on "The Colonies and Dependencies of the Netherlands and of Portugal," by Mr. A. J. R. Trendell, C.M.G.—Wednesday, 18th January, 8 p.m. Ordinary meeting. Papers to be read on "Methods of Taking the Ballots," by Messrs. John Leighton, James Withers, and John Imray.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, 17th January, 3 p.m. Lecture on "Before and After Darwin," by Dr. G. J. Romanes.—Friday, 20th January, 9 p.m. Lecture on "Diffraction of Sound," by Lord Rayleigh.—Saturday, 21st January, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

ROYAL STATISTICAL SOCIETY.—Tuesday, 17th January, 7-45 p.m. Paper to be read on "Progress, Organisation, and Aims of Working Class Co-operators," by Mr. Benjamin Jones.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—Wednesday, 18th January, 7 p.m. Paper to be read on "Steel Sleepers," by Mr. H. T. Munday, Assoc.M.Inst.C.E.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, 18th January, 7 p.m. Paper to be read on "The Non-Instrumental Meteorology of England, Wales, and Ireland, 1878-1885," by Mr. G. M. Whipple, B.Sc., F.R.Met.Soc., F.R.A.S. To be followed by the Annual General Meeting of the Society, when the Report of the Council will be read, the election of Officers and Council will take place, and the President, Mr. W. Ellis, F.R.A.S., will deliver his address.

CHEMICAL SOCIETY.—Thursday, 19th January, 8 p.m. Papers to be read "On Morindon," by Messrs. T. E. Thorpe, F.R.S., and W. T. Smith, M.B. (Lond.); on "Manganese Trioxide," by Messrs. T. E. Thorpe, F.R.S., and F. J. Hambly; "Contribution to the Theory of the Vitriol Chamber Process," by Professor Lunge; and "Studies in Coal Distillation," by Mr. Lewis T. Wright.

ARCHITECTURAL ASSOCIATION.—Friday, 20th January, 7-30 p.m. Ordinary meeting. Paper to be read by Mr. Somers Clark, F.S.A.

PRICES CURRENT, 12TH JANUARY.

Quotations at per ton, unless otherwise specified.

"	Australian	168	0	0	"	——		
"	English Ingots	148	0	0	"	——		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—The market price has varied little during the week, Chili bars having been kept firmly at from £85 to £86, with little business doing. Manufactured copper remains at £90 "strong," with small demand. The high quotations are bringing out large quantities of old copper and brass, which enables the brass and copper manufacturers to keep out of the market, and to cover their small requirements on favourable terms. Large quantities of old copper rollers are being sent from this district to Birmingham. When these outside lots are cleared off the position of the copper market will be much stronger, and foreign buyers will have to pay full rates for their requirements.

TIN remains steady, Straits being quoted about £167 per ton, and English about £148. It is strongly held by speculators, but the prospect of larger supplies coming forward shortly makes buyers cautious, and very little business is being done.

LEAD.—Quotations are a little easier.

SPELTER remains unaltered, but the price is quite firm, and the arrivals are readily disposed of at full prices. This metal is in demand for forward delivery to cover large inquiries for galvanised iron and wire goods, and is likely to remain at present values.

STEAM NAVIGATION IN THE DUTCH EAST INDIES.—The Dutch-Indian Steamship Company has given notice to the Government at Batavia to terminate its contract for carrying the mails, &c. This is a local company which maintains steam communication between the various islands; but the directors have practically decided to now extend their operations to Europe, by establishing a new line of steamers between Rotterdam and Batavia.

HOME INDUSTRIES.

MANCHESTER, 12th January, 1888.

The Engineering Trade.—Engine builders have been well employed during the past few weeks with repairs, as is usually the case at holiday seasons. The improved state of trade is inducing manufacturers to get their machinery into good condition, so as to enable them to take full advantage of it. Except for export orders there is not, however, much new work being executed; but the amount likely to come from that source in the immediate future is considerable. Millwrights have been fairly employed during the holidays; but many of them are anxiously looking forward to a development in trade, so that they may obtain orders to replace those which they have at present on hand. Machine tool makers are finding inquiries more numerous, and although there is not yet such an increase in the bulk of work being executed by engineers throughout the country as to call for more machine tools, there is sufficient enterprise awakened as to justify many of them preparing for the prosperous days believed to be at hand. Boiler makers continue to be well employed, and the same remark applies to machinists. The latter are altogether better off than any others engaged in the engineering trades in the district, and there is hardly a firm making textile machinery which is not fully supplied with orders for many months to come. In some cases there will be no lack of orders during the year, and appearances point to a very prosperous time for machinists. There are rumours of extensions by various firms, amongst the most authentic being that of the acquisition of the premises erected by the late Mr. Evan Leigh by a very successful firm of spinning machinists. Up to the present, however, the rumour lacks confirmation. Loom makers commence the year full of work, but are hardly likely to have such a successful year as the last two. Locomotive builders and gas engine makers are better employed. It is gratifying to be able to note that the Board of Trade returns for the past year show a very substantial advance in the amount and value of the machinery and mill work exported, a great part of which comes from this district.

The Iron Trade.—The attitude of the market at present is one of anticipation. The various quarterly meetings are being held this week, and it is expected that iron will be materially advanced in price. There is beyond doubt a greater inclination to purchase generally, and an undoubted increase of production in various ways, so that the rise in pig iron is quite justified. The quotations for steel are hardening gradually, and it cannot now be bought at much less than £7 per ton for good brands of round and square bars. Boiler plates in this material have advanced from 25 to 30 per cent., and all round the position is better. Bar iron of common makes is now being quoted 2s. 6d. to 5s. per ton above the old rates, and there is an increasing disposition to decline forward sales. The various brands of marked irons are more awkwardly placed than common bars, as makers feel the competition of steel very severely. There is no doubt that this class of iron would be much higher in price if it were not for the fact that steel is used in its place wherever prices become nearly equal. Turning bars for shafting purposes are now at a base price of £5. 15s. per ton.

Large Copper Pans.—Messrs. Thos. Ryder & Co., of Manchester, have just completed some copper pans for a brewery in Liverpool, which are of an unusual size. The bottom plate is 9ft. in diameter, and formed of one copper plate hammered and raised at the edges for the flanges. This plate is 1⅛in. thick, so as to withstand the action of the furnace. Vertically the pan is in two sections, the lower one being bulged in the usual way, and having a depth of 3ft., and a maximum diameter of 11ft. 6in. Above this is a cylindrical portion 4ft. 8in. deep and 12ft. diam., this being surrounded at the top by a double flange 18in. wide. The thickness of the copper used varies from 1⅛in. to $\frac{3}{16}$in., and the cubic capacity is equal to 4400 gallons of liquor.

LONDON, 12th January, 1888.

The Money Market.—The comparative abundance of money, which keeps rates in the money market down to low figures, is a little surprising considering the evidences afforded on every side of the continuous improvement in trade. One would expect that less money would be forthcoming for lending purposes, and that less of it would be available for Stock Exchange uses when trade is expanding. Still there seems to be no diminution in the supply, and rates remain much below the official rate. The Bank rate becomes more and more an anachronism, for its movements seem absolutely unrelated to the actual conditions of the money market. One proof of the distinct improvement in trade all over the country is afforded by the dividends just declared by the joint stock banks throughout the kingdom. Their returns are most reassuring, and in many cases the dividends paid for several past half years have been exceeded. In the stock markets British Funds continue to stand unprecedentedly high. The new Local Loans stock is eagerly taken at a substantial premium, and Consols have recovered from the fall which set in upon the growth of fears of possible early conversion. The first issue of the new Local Loans annuities was made in exchange for Consols, whereby the Government lost a large portion of the premium, and those who made the exchange got a good bargain. When the exchanging was stopped, Consols strengthened, partly because of the hope that the official broker would resume the issue of the new stock on terms so advantageous to Consol holders. Needless to say, he did not. All British, Colonial, and corporation stocks have been exceedingly strong. Home railway securities maintain their position, especially the "heavy" ones. The foreign market is unsettled and weak. It has been shaken by the failure of a Parisian speculator, whose fall has also disturbed the market for mining shares. Thus, though copper itself gains, the shares of the leading copper mines have not moved correspondingly.

Companies.—Since our last report the following new companies have been registered:—Shippey Brothers, Limited, with a capital of £30,000, to carry on business as electrical engineers and lighting contractors; Wright, Butler, & Co., Limited, with a capital of £350,000, to carry on business as iron smelters, engineers, steel manufacturers, &c.; Lucigen Light Company, Limited, with a capital of £250,000; Morata Valley Company, Limited, with a capital of £120,000, to acquire certain mines, railways, and tramways in Spain; West Moodie's Gold and Exploration Company, Limited (Transvaal), with a capital of £100,000; the Santa Teresa Copper Company, Limited, with a capital of £250,000; Durban Roodepoort Gold Mining Company, Limited, with a capital of £90,000.

Railways.—The gross receipts of the twenty-two principal railways in the United Kingdom for the week ending 1st January, amounted to £1,114,368 on 15,814½ miles, as compared with £1,063,575 in the corresponding period of 1887, when the mileage was 15,706¾ miles. An increase is thus shown in the mileage of 107¾, or 0·6 per cent., and in the receipts of 4·7 per cent.

Picric Acid.—An Order in Council has been issued under the Explosives Act, 1875, declaring, as picric acid, picrates, and mixtures of picric acid with other substances are under certain conditions specially dangerous by reason of their explosive qualities, that—"(1) Picric acid when in process of manufacture or storage shall (for whatever purpose used or manufactured) be deemed to be an explosive within the meaning of the said Act for all the purposes of the said Act, subject to the exceptions following: (*a*) Picric acid when wholly in solution shall be exempt from being deemed to be an explosive within the said Act; and (*b*) picric acid which does not fall within the exemption above set forth, but which is being manufactured or stored in a factory, building, or place exclusively appropriated to the manufacture or storage of picric acid, and in such manner as effectually to prevent any picric acid from coming into contact (whether under the action of fire or otherwise) with any basic metallic oxide or oxidising agent, or other substance capable of forming with picric acid an explosive mixture or explosive compound, or with any detonator or other article capable of exploding picric acid, or with any fire or light capable of igniting picric acid, shall be exempt from being deemed to be an explosive within the said Act. (2) Picrates and mixtures of picric acid with any basic metallic oxide, or any oxydising agent, or with any other substance capable of forming with picric acid an explosive mixture, or an explosive compound (for whatever purpose used or manufactured), shall be deemed to be an explosive within the meaning of the said Act for all the purposes of the said Act unless such picrates or mixtures be wholly in solution."

Mining Accidents.—The number of persons killed by explosions in mines during 1887 was 142, an increase of 13 on the previous year. This shows a large decrease on the average of the ten years between 1876 and 1886, which amounts to 250.

The Navy.—There are at present being built in the Medway yards two second class cruisers, one sloop, one first class gun vessel, and one surveying ship. At Portsmouth only two vessels are in course of construction, viz., the twin screw cruiser "Melpomene" and the twin screw sloop "Nymphe."

GLASGOW, 12th January, 1888.

General Trade.—The holidays are in the too immediate past for trade to give any definite indications. The stream of shipbuilding orders has somewhat slackened, though a few of some importance are still being given. Engineering is fairly brisk. Boiler makers are also in some cases extremely busy. The coal trade has been affected by the holidays, and shipments have been moderate. The same cause has affected mineral shipments generally. Railway traffics show no exceptional feature. Goods traffic has slightly improved; but passenger traffic shows a slight falling off. The sugar trade is exceedingly active, and prices have still been tending upwards. Freights are not quite so firm as they were; the probability of a considerable accession to shipping in the early future naturally depresses the freight market to some extent.

Shipbuilding.—Messrs. Thomas Cook & Sons, who have the Khedive's concession for the passenger traffic on the Nile, have ordered from Messrs. Bow, McLachlan & Co., Paisley, three paddle steamers for this service. The vessels will be fitted with triple expansion engines, and will be luxuriously furnished. In addition to the large steamer, the contract for which we noted last week, Messrs. W. Denny Brothers, Dumbarton, have secured an order for another steamer of 5000 tons for the Compania Transatlantica of Spain. A contract has been placed with Messrs. David J. Dunlop & Co., of Port Glasgow, for two steel screw steamers, each of 500 tons gross, for passenger and cargo trade. The vessels will be supplied with triple expansion engines.

Shipbuilding.—It is reported that Messrs. Napier, Shanks, & Bell have booked an order for a large paddle steamer for a Japanese company. This firm has been fairly busy during the dull times with a number of small craft, and now have two vessels of large dimensions on hand.

Engineering.—Messrs. Bow, McLachlan, & Co. have contracted with the General Steam Navigation of Calcutta for two sets of engines for twin screw steamers for river service.

Iron and Steel.—Prices of pig iron appear for the moment to have given way. Warrants have dropped, and iron masters have reduced their prices. Steel makers are still busy. The large amount of shipbuilding material for which they hold contracts is in the meantime maintaining prices. The prices quoted at present are: Angles, £6. 10s.; ship plates, £7. 10s.; boiler plates, £7. 17s. 6d.; rivets, £7.

The Admiralty and Scotch Coal.—The coal masters in the Slamannan district have selected the coals of Arden and Stanrigg (Messrs. Wm. Black & Sons), Longrigg and Longriggend (Messrs. James Nimmo & Co.), and West Longrigg (Mr. James Gemmell), as typical of their district, for the purpose of the Admiralty trials which are shortly to be made.

The Electric Light at the Vienna Opera House and a Glasgow Firm.—A communication from Vienna to the *Glasgow Herald* states that the failure in the electric light at the Opera House has been found to be due to defective boilers, and that a new set of six boilers has been ordered from the Babcock & Wilcox Company, of Glasgow.

(From our own Correspondents.)

LIVERPOOL, 11th January, 1888.

The Timber Trade.—There is an undoubted improvement in the timber trade, and the prospects for the New Year appear much brighter than was anticipated a few months ago. The consumption of pine timber for the last month amounts to about 123,000 cub. ft., a marked increase on the amount for the corresponding month in either 1886 or 1885. Red pine is very scarce, and will meet with a ready sale. There is a large stock of oak in hand, especially in planks, amounting to about 117,000 cub. ft.: the consumption has been an average one, about 32,000 cub. ft., but at increased prices, and the stock on hand will, no doubt, realise fair prices. The R.B. and N.S. spruce and pine deals still maintain their higher rates, but there is no material improvement in the prices of Quebec deals. Pitch pine has slightly advanced in price. About 4000 cub. ft. of elm have been sold, leaving the present stock at about 39,000 cub. ft. A similar quantity of ash has been sold, leaving a stock of about 18,000 cub. ft. There is a demand for Honduras mahogany at satisfactory prices; Minatitlan and Tabasco is also in good demand, but the stock of both is very small. There is practically no Cuba or St. Domingo in stock, and suitable logs will find a ready sale upon arrival; curls are in good request. There is no African mahogany in the market. There is a good demand for Honduras, Mexican, and Cuban cedar, the stock, however, being very limited; but of South American and pencil cedar there is a good stock, and prices are low.

SHEFFIELD, 11th January, 1888.

Heavy Manufactures.—As an evidence of the increasing demand for iron, it may be stated that in the Sheffield district there are no fewer than sixteen additional puddling furnaces alight. This means a considerably enlarged output, yet stocks are comparatively small, and one or two firms have actually a difficulty in meeting requirements. Bars are selling at £5. 5s. to £5. 7s. 6d., and hoops at £5. 10s., and even £5. 12s. 6d. Crucible and Bessemer are in very large demand. There is more work at the gun shops of Messrs. Thos. Firth & Sons; and Messrs. T. Vickers & Sons are busy on shipbuilding material. At the armour plate shops of the Atlas and Cyclops Works operations are brisker, and Messrs. William Jessop & Sons are doing an extensive trade in crucible cast steel castings, There is also a more eager inquiry for railway material, not only for steel rails of various sections, but for tyres, axles, and springs; for the latter Messrs. Thomas Turton and Sons have recently received one or two excellent orders. For edge tools there is a better market, and both Sheffield and Dronfield houses are doing well. Colliery plant is also in more active request. At a number of the pits in the locality there have been many renewals, one colliery company alone having just put down no fewer than 6000 yards of steel hauling wire.

Order for Dredger Buckets.—The Hadfield Steel Foundry Company have secured the order for the whole of the buckets and general steel castings required for the dredger ordered by the Preston Corporation from Messrs. Fleming & Ferguson, as referred to in your Glasgow trade report in your last issue. The same firm has been successful in securing a good order for similar material from the Panama Canal Company.

LEEDS, 11th January, 1888.

Iron and Steel.—Trade in manufactured iron is much healthier, and now that Leeds has launched into steel manufacture, there may be a considerable development of the local steel trade during the year. The rapid improve-

Digitized by Google

ment in the shipping trade has resulted in capital orders for Leeds, shipbuilding material of all kinds being in great request; prices for iron and steel plates are quoted with caution. Messrs. Tannett, Walker, & Co. are busy on hydraulic machinery, and will be for some months to come, having received several large orders. At Messrs. Kitson & Sons' there is more doing in the locomotive construction shops, and the firm are also sending out a number of steam tram engines. Fittings for Yorkshire mills are finding employment, too, for many hands; but there is little call for agricultural machinery.

TEXTILES.—The improvement in the heavy branches is having a beneficial effect upon the textile industries. There is undoubtedly more money stirring, and fabrics are bought up with much readiness. Fancy worsteds are selling well, and so are woollens in new patterns. The ready made clothing factories are busy with spring goods.

NORTH STAFFORDSHIRE, 11TH JANUARY, 1888.

THE IRON TRADE.—Since the holidays some good orders and specifications have been received, and inquiries are numerous. Makers are firm in regard to prices, but as a rule little, if any, advance is secured. The quarterly meeting of the North Staffordshire Coal and Iron Masters' Association was held at Stoke on Monday last, when a draft of proposed special rules for local collieries was presented by the committee who had been appointed for the purpose. After a lengthy consideration the meeting was adjourned for a month, to enable colliery proprietors to look further into some points upon which a discussion arose. Sales were generally deferred until the quarterly meeting to be held to-morrow at Birmingham. Amongst local iron masters there is a feeling of satisfaction at the re-construction of the old South Staffordshire Wages Board, by the decisions of which wages have been governed in this district. On the whole, a hopeful feeling prevailed with regard to the future, but no material rise in prices was anticipated for the present. Of the forty furnaces in existence only eighteen are now in blast. Messrs. Robert Heath & Sons have recently put one into operation.

THE POTTERY TRADE.—Work has now been generally resumed at the manufactories, and there is a fairly good outlook in this industry. The demand for manufacturing fuel is satisfactory, and some heavy contracts are being entered into for the next twelve months' delivery.

BIRMINGHAM, 11TH JANUARY, 1888.

THE HARDWARE TRADE.—The effect of the holidays has now passed off, and work has been resumed in most of the factories in the district. In the brass trade, however, and especially among the smaller manufacturers, the high price of copper is checking business. The reason for this is the increased value of stock, much of the old stock being sold off at the former low prices, and when the time for replenishing comes, a difficulty is experienced as regards capital. The buying public has not yet quite realised that the holders of copper will most probably be able to control the market for some time to come, and there is consequently a hesitation to place orders. These causes combined are influencing the market adversely. Business with foreign markets in general hardwares, guns, bedsteads, &c., continues to maintain itself very fairly. Washing machines, hinges, coffin furniture, brass and iron tubes, nails, picks, shovels, and iron tools are mentioned as being in good request.

THE IRON TRADE.—This industry shares the increased prosperity which characterises it generally throughout the country. The market is strong, and there are a large number of inquiries. Galvanisers are busy, but complain that in order to meet the increased value of black sheets and spelter they should be getting about £1 per ton more for their staple goods. Sheets are strong at £6. 5s. to £6. 10s. for singles, and £6. 15s. to £7 for doubles, with tubes and other varieties of manufactured iron at corresponding rates.

LEICESTER, 11TH JANUARY, 1888.

WOOL SPINNING AND YARN TRADES.—Up to the time of writing the trade of the New Year shows no improvement on that which we were having before Christmas. Though there is no increase of business, a very buoyant and hopeful tone pervades the market, and holders of wool are extremely firm in demanding late rates. Thus sales are only for urgent wants, as users are disinclined to buy beyond their immediate needs, and wool staplers are holding out. Country dealers and growers are also of the same mind, and will not part with their holdings at any reduction. It is not likely that much will be done in the wool trade before the next London sales. Spinners are cheerful, but they experience no pressure of demand, though a few fairly good lines are already booked. Inquiries are more frequent for yarns for the spring trade; but prices are still very unremunerative, and not quite in accord with the cost of the raw material; hence spinners are reluctant to book large contracts. Yarn merchants have not yet commenced to be active, though they are perceiving a slight movement in trade.

HOSIERY TRADE.—Business has re-commenced very quietly indeed; but on the whole manufacturers are not greatly dissatisfied, as there are indications of an improvement in the immediate future, and buyers have commenced to look round the new samples. There are some heavy Government contracts in hand in the district.

BOOT AND SHOE TRADE.—There is no improvement in the trade as yet; the depression of the latter part of last year continues, and short time is the rule in the town and district.

SOUTH WALES, 11TH JANUARY, 1888.

TRADE ACTIVITY.—The Dowlais Works are said to have obtained an order for 20,000 tons of steel rails for the Argentine Republic, the price named being £4 per ton f.o.b. Welsh port. It is also stated that the Cardiff Workmen's Cottage Company have leased a plot of land on the East Moors, in the neighbourhood of where the new Dowlais works have been commenced, and that six hundred workmen's cottages are to be forthwith built. The iron works at Treforest, which have been standing idle for many years, have been acquired by a company, of which Sir W. Lewis is chairman, and have been re-started under the named of the Forest Steel and Iron Works. It is also announced that preliminary arrangements have been made by some influential capitalists to construct another large dock at Milford Haven, an enterprise which will involve an expenditure of nearly a quarter of a million.

THE COTTON INDUSTRY.—Cardiff was some few years ago threatened with partial extinction by the Barry scheme; but circumstances seem to have worked in such a manner for its good as to make the very obstacles in its way only stepping stones for its progress. The influence and energy which were diverted to Barry have simply left a void which is being filled by new activities, and it is now actually stated that a number of Lancashire gentlemen interested in the cotton manufacture have a scheme on hand to erect a number of cotton mills, each to contain 50,000 spindles, the whole to cost upwards of half a million sterling.

CARDIFF WATER WORKS.—A special pumping plant to take water from the Ely River is about to be laid down to increase the supply which will be required by the Dowlais Company. The Barry Gas and Water Works Company have applied for a similar arrangement to be entered into with them as that which has already been detailed in *Industries* for the supply of the new Dowlais works.

BARROW-IN-FURNESS, 11TH JANUARY, 1888.

DREDGING AND DOCK WORK.—During the current year it is proposed to deepen Walney Channel, between the Barrow Shipyard and the Graving Dock, owing to the fact that much silting up has lately taken place, and the dock can only be approached at high water. It is also contemplated to extend the wharfage in the entrance basin of the Ramsden Dock, so as to afford greater convenience for an increasing shipping trade, which will in the ordinary course of things follow, firstly, the establishment of a service of steamers in connection with the Foreign Food Supply Company; secondly, the greater activity in the iron and steel trades; and thirdly, the contemplated great development of the shipbuilding and engineering trades of the port.

IRON AND STEEL.—The iron market has recovered from the weaker tone shown last week, when prices dropped 2s. per ton; but now prices are up again at 46s. per ton net f.o.b. for mixed numbers of Bessemer iron, and 45s. 3d. for No. 3 forge. There is a good inquiry for forward deliveries, and makers in the meantime are busy and are well sold forward. Stocks are less bulky than they have been, and deliveries both by sea and rail are well maintained. The steel trade is very active. There is still a great demand for shipbuilding material, and plates have advanced from £7. 5s. to £7. 10s. per ton net f.o.b., while angles are at £6. 15s. per ton. Rails are in good demand for both home and foreign markets; but although there is an improving tone, prices are steadily held at £4. 2s. 6d. for heavy sections. It is thought probable that an advance will soon be established, because makers are so full of orders and so well sold forward. All branches of the steel trade are busy, and the output is far in excess of any previous time.

MIDDLESBROUGH, 11TH JANUARY, 1888.

PIG IRON.—The pig iron market remains firm at 33s. per ton for No. 3 G.M.B. prompt, and 33s. 6d. to 34s. for forward delivery. Warrants are 33s. per ton cash, hematite warrants 44s. 6d. to 45s. The retrospect of the past year is full of hope and promise for the year which is before us. There are six more furnaces in blast at the close than at the beginning of the year, and, of course, the total make is greater. But the shipments, local consumption, and rail deliveries have increased more than correspondingly, so that stocks, which amounted to 652,445 tons at the close of 1886, stood at 637,682 tons at the close of 1887. Prices also compare favourably, the average of 1887 being 3s. 6d. above that of 1886.

MANUFACTURED IRON AND STEEL.—Finished iron still maintains the advance made at the close of the year, prices being fully maintained. Inquiries are more numerous than ever, and in some instances there is a difficulty in getting the work done. This has made a strong demand for forge iron, for which 32s. 6d. per ton has been paid. Common bars are £5, best bars £5. 10s., ship plates £5, boiler plates £6 per ton, all less the usual discount. The steel works are pressed with work. Indeed, the demand for ship plates is so great that the works cannot keep pace. From £6. 10s. to £7. 5s. is the price now being paid for steel plates; £7 is the average.

SUNDERLAND, 11TH JANUARY, 1888.

SHIPBUILDING.—The actual prospects of local shipbuilding can now be fairly gauged. At the present time work is actually in progress on twenty-nine vessels—twenty-eight steamers and one sailing vessel, either afloat or on the stocks—of about 59,000 tons gross register. This is less than at the beginning of 1887, when there were thirty-five vessels of over 67,000 tons; but the latter figures included a number of vessels thrown on the builders' hands, on which work was but nominally in operation. The work yet to be commenced forms, however, the most important factor of the future. In January, 1887, there were eleven vessels of 19,000 tons ordered, but not visible in the shipbuilders' yards. In January, 1888, there are twenty-five vessels of 53,000 tons, or nearly three times the amount of work. Altogether there is at least 112,000 tons of shipping at present building or to be built on the Wear, the bulk of which has been ordered during the last three months, as compared with 86,000 tons in January, 1887.

THE COAL TRADE.—Now that the statistics of the year 1887 have been compiled, it is satisfactory to find that there has been a substantial increase in the shipment of coals during last year. No less than 2,497,896 tons were shipped coastwise, an increase of 70,279 tons as compared with 1886; while 1,496,002 tons of coal were shipped abroad, an increase of 174,482 tons; and 63,921 tons of coke, an increase of 21,837 tons. The total shipment of coal and coke was 4,058,037 tons, and allowing for a slight decrease in the coke shipped coastwise, there was the gratifying increase of 266,429 tons. Sunderland to some extent prospered in 1887 by the diversion of the coal trade, consequent on the strike of the Northumberland miners.

NEWCASTLE, 11TH JANUARY, 1888.

SHIPBUILDING.—Since the opening of the year most of the Tyne shipbuilders have secured additional contracts, and the yards have generally assumed an appearance of greater briskness. Among other contracts placed may be mentioned one for the building of four steel steamers of large size, which has been obtained by Messrs. Hawthorn, Leslie, & Co., from a Scotch firm of ship owners. Messrs. Stephenson, of Hebburn, have just booked an order for a third vessel of large size. Messrs. Swan & Hunter are now engaged in laying the keels for four large vessels, a circumstance which indicates the early advent of an exceptionally brisk period in the yard. Messrs. Armstrong, Mitchell, & Co. are proceeding with the construction of two vessels, one of which is to be considerably over 400ft. long. This firm have no less than five vessels being fitted out beside the yard, and another steamer of special build and large dimensions will shortly be put off the stocks. Messrs. Dobson & Co. have put down the keel for a medium sized vessel this week, and the whole of their four berths are now occupied. Messrs. Palmer's frame furnaces are now kept going night and day, and there is reason to believe that this method of working will be continued for some months to come. Messrs. Edwards and Messrs. Readhead have both secured orders lately, and one or two other firms that have been doing scarcely anything for some years past are understood to have acquired sufficient work to make their establishments tolerably busy for the remainder of the year.

ENGINEERING.—Exceptional briskness continues to be the feature at the leading marine engineering establishments, and one or two factories that have not hitherto been busy with marine work, are now likely to share in the general activity. Messrs. Black & Hawthorn have some good orders for the modern type of marine engine, the execution of which will be commenced as soon as a large hauling engine is put out of the shops, which event is expected to take place early next week. This firm are now erecting a spacious new shop, which is to be used exclusively for the manufacture of the "Beck" gas engine. Messrs. R. Stephenson & Co. are now busy with the patterns for a set of marine engines, and the order for a second set has been obtained. The firm have also booked orders for a limited number of locomotive engines, and they are doing a good deal of work in the general repair line. At the Elswick Ordnance and Engineering Works the same brisk state of business is to be noted as has existed for many months past.

BELFAST, 11TH JANUARY, 1888.

SHIPBUILDING.—Increased activity is still the rule with this department, and the New Year opens with very bright prospects, almost all the yards on this side of the channel having a large amount of work before them. Several orders were placed just before the holidays, all for vessels of large tonnage.

ENGINEERS AND BOILER MAKERS.—Though still suffering from the late depression, there is a fair amount of business being done, and in several cases boiler makers have received orders sufficient to afford occupation for some months.

LINEN TRADE.—After the interruption caused by stock-taking and the holidays trade has brightened all round, and a large amount of business is being done, with prices somewhat firmer. In yarns there is a good business passing, with hardening prices. The trade in wefts is considerably improved, and in some cases better prices have been obtained. Tows have advanced 1½d. per bundle, and are still in satisfactory demand. Cloths continue in request at firm prices, and several good orders are in hand.

SMILES' HOLE CUTTING MACHINE.

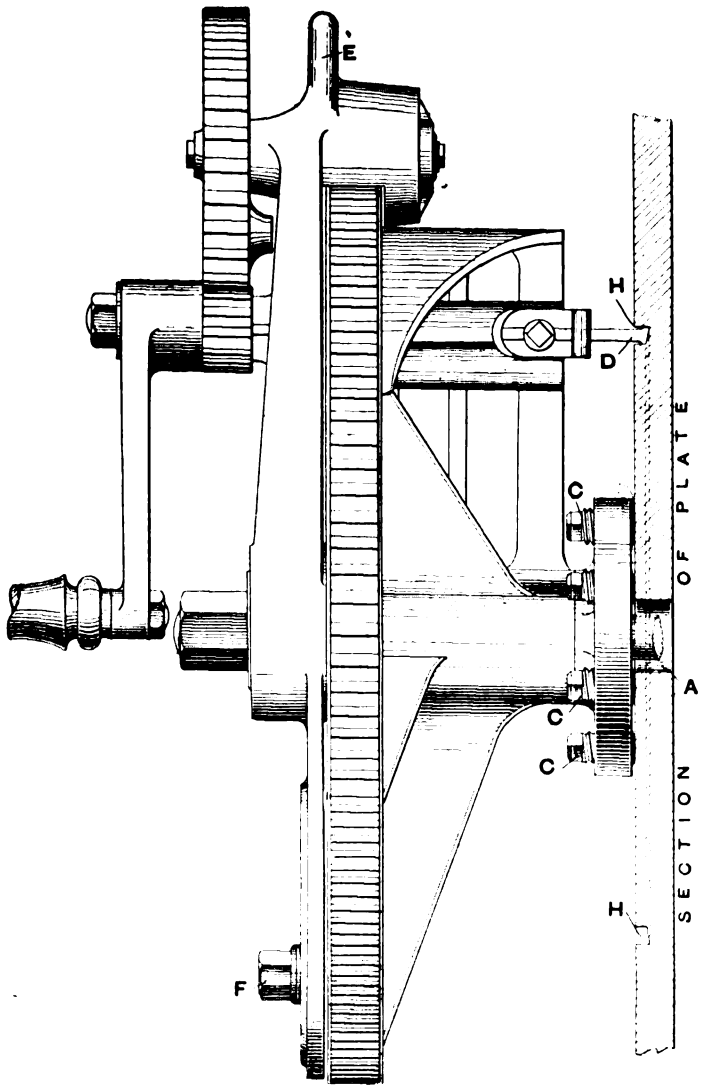

FIG. 1.—END ELEVATION.

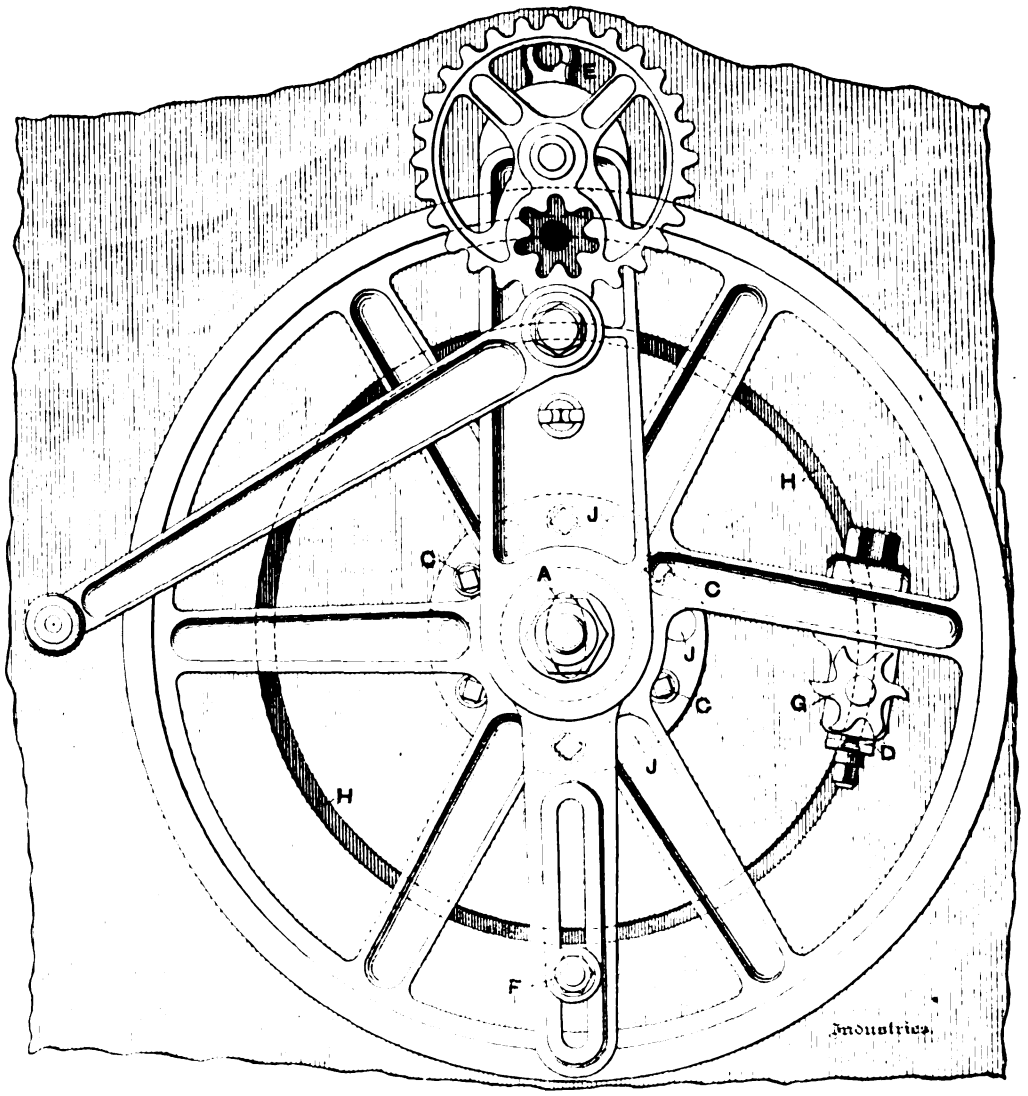

FIG. 2.—FRONT ELEVATION.

SMILES' HOLE CUTTING MACHINE.

MR. GEORGE THWAITES, of Stockton-on-Tees, exhibited at the late Newcastle Exhibition Smiles' patent hole cutting machine, shown in the above illustrations. The advantage claimed for this machine is that holes may be cut into the shell plates of a vessel by machinery after they are put in position, whereas formerly, especially in cases where sufficiently powerful hydraulic or steam machinery is not available for cutting or punching out the holes, the perforations had to be cut before fixing the plates in position. Special machinery for punching large holes does not appear to be economical, as time is lost in moving plates from one machine to another, and the first cost and maintenance of large hydraulic punching machinery is considerable. In order to overcome these disadvantages, Mr. Smiles designed the above hole cutting machine. It is made in three sizes, and our illustrations show the intermediate size, which is capable of cutting holes from 6½in. to 15½in. diam. The smaller size cuts holes from 4in. to 9in. diam., and the larger one holes from 8in. to 21½in. diam. These machines have been designed with a special view to lightness, while insuring strength and rigidity—steel and malleable iron being solely used in their construction. Fig. 1 shows an end elevation of the machine attached to a plate. A small oval perforation A is made in the centre of the proposed position of the hole, and an oval headed bolt inserted from the outside of the plate, and turned through 90° before screwing up. In some shipbuilding yards where the machine has been used, the hole for inserting the central bolt has been punched out at the same time as the rivet holes. If it be convenient to insert the central bolt from the inside of the vessel, the hole need not be oval. In cases where the plate is curved the machine is set by means of set screws C. The tool D lasts a considerable time, and may be easily replaced when worn out. An eye E is provided for attaching a rope for slinging the machine over the ship's side. In Fig. 2 a front elevation of the machine is shown attached to a plate. The pin F moves the star wheel G, thereby feeding the tool D. J J are tempered steel claws, which grip the plate so as to prevent the machine from turning round the central bolt.

COAL, IRON, AND COGNATE INDUSTRIES.

"THE probabilities of the continuation and development of the revival in trade during the year appear to outweigh the anticipations of the pessimist." Such was the conclusion arrived at in our review just twelve months ago with reference to the course of these trades during 1887, a conclusion which has been justified by the event. The Board of Trade Returns for December and for the past twelve months have now been issued, and from whatever standpoint regarded they cannot fail to cause satisfaction. The figures relating to our iron and steel exports show an increase for the month of 84,309 tons in quantity and £467,502 in value, as compared with December, 1886. In pig iron the month's increase is a substantial one, amounting to £88,347, or nearly 71 per cent., and is mainly due to an improved demand from the United States, Italy, and Holland; our trade with Russia and France being greatly diminished. The exports of railroad iron for December exceed those of the corresponding month in the previous year by as much as £230,274, or rather over 102 per cent. It is somewhat difficult to account for a decrease of £33,766, or 19 per cent., in the value of the past month's exports of unwrought steel, almost entirely attributable to a reduced trade with the United States. Having thus dealt with the main features of the returns for December, we are enabled to utilise our tabular statement for a comparison of the aggregate exports of the past three years:—

	Twelve months, ending December 31st. 1887.	1886.	1885.
	£	£	£
Pig and puddled iron...	2,741,507	2,254,497	2,029,816
Bar, angle, &c.....	1,447,977	1,373,071	1,620,484
Railroad	4,617,460	3,687,382	3,905,259
Steel, unwrought	2,094,454	1,493,669	1,027,460
Coal	10,176,402	9,837,338	10,633,151

Beyond the evidence thereby afforded of an improved business with foreign nations, the above figures must convey to the mind of the most casual observer one fact, very significant as a sign of the times, viz., that whereas the amount of bar and angle iron exported has slightly decreased during the past two years, that of unwrought steel has been more than doubled.

We have already furnished our readers with statistics relative to the home trade of the past year in the industries under review, and propose now rather to very briefly summarise the variations in the "tone" of the markets, and to notice the contributory causes. It will be in the recollection of those interested that until quite recently at home the promises of the opening months of 1887 had not been in any way realised. Indeed, a further fall in values had occurred, and in many instances prices ruled below the cost of production. It is perhaps unnecessary to do more than refer to the numerous failures which have occurred, and to the works which have been closed during the past twelve months, to conclusively prove the continuation of the depression. In the early part of December, however, a change occurred. At the various centres of the iron trade the price of crude metal advanced, and that of tin and copper rose by leaps and bounds. The latter was due to the operations of a wealthy French syndicate, assisted by a reduced supply of the metals in question. With regard to the former, it may be noted that, although stocks were still increasing, there had been some improvement in several branches of the finished product, and the influence of the Board of Trade returns also made itself felt. As to tin and copper, a tremendous fall from the abnormally high prices now reached through the exigencies of speculation is only a question of time; but there is reason to believe that a natural and legitimate expansion of demand, and, consequently, an advance in the price of finished iron, may more than sustain the improved tone of the pig iron markets. In face, however, of the enormous stocks existing at nearly every industrial centre, and of our high productive capacity—a considerable proportion of which is now lying dormant, but would be brought into operation if trade improved—it is difficult to discern any substantial indications of a materially higher cycle of prices in the immediate future.

With regard to the relations of capital and labour in the mining world, we confess to some disquietude. While advocating without stint the recognised right of the workmen to participate in the prosperity of their employers, should a revival in prices really occur, we cannot but deprecate the leaning of many of their present counsellors towards shorter hours of labour.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Industries, VOLS. I. & II.

July to December, 1886, and January to June, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 13TH JANUARY, 1888.

THE TRADE OF THE PAST YEAR.

THERE is a general feeling in the chief industrial centres that the New Year begins with better promise than did the old. The autumn revival of 1886 was dissipated ere 1887 had well begun; but this year the revival came later, and bids fair to last longer. The only cloud in the sky is the prospect of Continental war, and this prospect has any time during the past ten years played its part in unsettling men's minds, and in checking the development of trade. But for the moment affairs seem to have settled down into an approach to calmness, and for yet awhile it may be possible to avoid the rupture which the excessive armaments of the great Powers reduce to a question of time. The year that has just ended has been comparatively free from striking incidents. Only towards its close have the President's Message, the boom in shipbuilding, and the copper "corner," given the year some elements of excitement. The Presidential Message has, indeed, been one of its great events. The announcement of a policy of free trade by the official head of the nation in general, and of the Democratic party in particular, indicates a victory for free trade principles in the United States sooner or later. The effect upon our commerce of the abolition of the American tariffs is somewhat difficult to forecast, yet our trade must be affected to some extent even by the anticipation of reduction, though the party warfare between Democrat and Republican on the tariff question is likely to be very prolonged. The rise in freights consequent upon the growing quantities of our exports and imports, accompanied by a wreck list scarcely covered by the addition to the mercantile marine of newly built vessels, led in the last three months of the year to the placing of exceptionally heavy orders at all the shipbuilding ports. This revival of the shipbuilding industry, accompanied by a general movement in metals due to other causes, aided in bringing about a considerable amount of briskness in iron and steel, which, on account of depression in the engineering trades, had been languishing for some months. One of the events of the year has been the formation of the copper "corner," and the phenomenally rapid advance in the price of that metal. A syndicate of French speculators had carried on a successful speculation in tin, and having apparently very extensive resources, were able also to turn their attention to copper. They bought heavily, and their operations resulted in rapid advances in the price, partly justified by shortcomings in the production in Chili. To this speculation has been traced by some commercial writers the revival in trade. If the revival has no more substantial basis than the operations of a small though moneyed clique, we need not count seriously upon its permanency. The cause seems rather to be found, however, in the great expansion in point of quantity of the products of manufacturing nations, leading to increased demand for means of transport, and this demand affecting us apparently disproportionately from the increasing importance of our position as the carriers of the world. Another explanation might be found in a reaction from the excessive depreciation of prices, a depreciation resulting largely through suppressed panic, a universal feeling of despondency, and a want of industrial confidence. A comparatively slight incident may at times put an end to such a feeling and produce a reaction, and this incident has doubtless been supplied by the increased demand for shipping, and the advance, partly genuine and partly speculative, in metals. Among the other commercial and industrial events of the year has been the reputed discovery of gold in quantity in Wales. Gold has long been known to exist in Wales, and it has even been worked there; but the present announcement is to the effect that ore of undreamed of richness is awaiting reduction in the Welsh hills. There is something of the fairy tale about the story, in spite of the high scientific opinion with which it is supported. Should processes be perfected which have been in the course of development during the past year for the reduction of extremely refractory ores, and should the Welsh ore show even a much smaller weight of pure gold to the ton than is claimed for it, it may be a speculation both profitable to the company and important to the nation. Meantime, inflated talk about the settlement of the currency question and the depreciation of gold by transmuting the Welsh mountains into coin may well be left out of account. Two depressed industries have during the year raised their heads. The Scotch mineral oil trade, overwhelmed by the petroleum of America and Baku, brought to this country in tank steamers, early in the year found itself in an extremely depressed condition. Oil shares fell rapidly; conversion, and in some cases liquidation, followed; all suffered seriously. An attempt was made to reduce wages, which was resisted. The struggle lasted for some months, and finally was terminated by a compromise. Since then the companies have been recovering their position: stocks are lower, prices are higher, and altogether the industry is in a much more healthy condition than it has occupied for some time. Few trades in the country have felt worse and grumbled to better purpose than the sugar trade. The innocent victims of "a glut," the sugar refiners in London and Greenock found their occupation practically gone. The importation of bounty-fed sugar from abroad swamped them. Firm after firm, of the highest standing, came to grief, and extinction seemed to be the inevitable doom of a business which apparently could not bear up in this country in the struggle for "the survival of the fittest." But the sugar refiners pleaded their hard case eloquently, the Government yielded, and convened a conference to discuss the abolition of the bounty system. Judging from present results, the work of the conference has been highly successful. Its first session terminated after the practical settlement of the question in favour of the abolition of the bounties so far as the delegates present at the conference were concerned. During the sitting of the conference sugar rose rapidly, so much so that not a few who had previously lost by the fall recouped themselves by the advance. Many articles which have more or less sympathetic relations with sugar also advanced rapidly in price. And chemicals, though on this occasion they did not lead the movement, were sharers in the enhancement of prices. Though it is premature to estimate, with any approach to statistical accuracy, the amount of the rise which has taken place, there can be no doubt that a decided check to the downward curve of prices has been given, and unless untoward events supervene to cause loss of the advantage gained, that some considerable portion of the heavy fall in

Digitized by Google

prices during 1885 and 1886 has been recovered. The general movement upwards in prices seems to justify the conclusion of the *Public Ledger*, which believes that "the sudden outburst of speculative activity during the early days of December has not been equalled since the year 1879." The year 1879, it will be remembered, marked the close of the crisis which came to a head in 1878. That the period of prosperity thereafter was of such brief duration was due largely to the wildness of the spirit of speculation which disorganised business and brought about the inevitable reaction.

Of legislation affecting industry passed during 1887, may be mentioned the Coal Mines Regulation Act, the Margarine Act, and the Merchandise Marks Act. A Bill dealing with boiler inspection and registration was proceeded with to some extent, and will probably be finally dealt with during the coming session.

THE COMMERCIAL DEVELOPMENT OF SHIPPING AND SHIPBUILDING.

II.

In our article last week we pointed out the general prominent position of British shipbuilding, but the volume of shipbuilding produced in this country has greatly varied as between one year and another, according as trade has been buoyant or depressed, as wrecks have been numerous or the reverse, and as the British Admiralty was giving out many or few orders. Within the last ten years we have produced as much as 900,000 tons in a single year, and as little as 350,000 tons in another. These extremes have not been greatly influenced by outside demands, for the tonnage built for foreigners has not usually been one-fifth of that built for our own requirements. The effect of such extremes has naturally been to unsteady the shipping and shipbuilding industries. It would be very desirable to secure greater uniformity, if that were possible; but shipbuilding follows the general trade of the world, and if that goes up by leaps and bounds, new ships must follow suit. Another matter that has caused a remarkable expansion of the trade within recent years, has been the extraordinary cheapness of tonnage. Until within the last five or six years, merchant steamers at less than £12 per ton were scarcely heard of. But within that period the cost of new tonnage has fallen as low as £6 or £7, which means that the ordinary market price of a new hull is not to-day much over one-half of what it was ten years ago. It is the opinion of many experienced shipbuilders that this low range of prices will be continued. Whether this is so or not, it must not be forgotten that the cost of production all round has been greatly reduced within recent years. Steel plates are not now costing much more than one-half of what they cost twelve or fifteen years ago. It is the same with angles, forgings, castings, engines, bolts and rivets, and everything else that enters into ship construction. This being the case, it is probable that there will be a larger demand for tonnage, relatively to the commerce of the world, than hitherto, since the tendency and effect of the cheapening of every commodity is to increase the demand for it.

In his new work, entitled "Uebersichten der Weltwirthschaft," published this year, M. Neumann-Spallart, a statist of the highest authority, gives the following table of the tonnage of sailing and steam ships respectively launched in the following countries, viz.: Great Britain, the United States, Germany, France, Italy, and Scandinavia in the period from 1873 to 1884:—

Year.	Steamships. No.	Steamships. Tonnage.	Sailing Ships. No.	Sailing Ships. Tonnage.
1873	680	470,457	3635	514,671
1874	595	381,567	4000	755,867
1875	586	261,033	3823	859,290
1876	533	194,484	3831	723,454
1877	597	279,670	3690	608,681
1878	713	380,095	3237	491,569
1879	656	427,380	2657	309,578
1880	807	508,773	2606	260,417
1881	861	635,941	2783	323,033
1882	1083	863,912	2738	389,107
1883	1370	994,797	2811	403,983
1884	1100	614,031	2849	409,378

Although M. Spallart does not carry his figures down to a later date than 1884, it may be remarked that during the two following years the production of tonnage has been much under that of the years 1883–84. Indeed, it is even doubtful whether the new tonnage constructed during the last two years has been equal to the replacement of the tonnage that has been removed from the registers of the world by wrecks and otherwise.

At the present time, the total tonnage of the merchant navies of the world amounts to about 20 millions of tons. In the latter half of the seventeenth century the total tonnage of the world's shipping was estimated by Petty at 2 millions. Nominally, therefore, our present tonnage is ten times that of two centuries ago. But this does not represent the full extent of the difference, for in the seventeenth century all the vessels employed were sailing ships, whereas there are now about 8,000,000 tons of steam shipping in the world, equal in carrying capacity to at least 24,000,000 of tons of sailing ships; and when to this we add about 12,000,000 tons of sailing tonnage we have a total of 36,000,000 tons, calculated as sailing tonnage only, or about seventeen times the estimated tonnage of the merchant fleets of the world in the time of Charles II. During the last six or seven years the total production of new tonnage in the whole of the leading shipbuilding countries of the world has averaged about a million tons per annum. About one-half of this tonnage goes in replacement of vessels lost by wrecks, &c.

The extent of the merchant navies of the principal countries of the world at the present time is indicated in the following comprehensive tabular statement—the most complete, we believe, that has ever been compiled—which we have extracted from Professor Neumann-Spallart's "Uebersichten:"—

Statement showing the Number and Tonnage of Steam and Sailing Ships in the Merchant Navies of the World.

Countries.	Steamships. No.	Steamships. Tonnage. 1=1000.	Sailing ships. No.	Sailing ships. Tonnage. 1=1000.	Steam and sailing ships. No.	Steam and sailing ships. Tonnage. 1=1000.
Great Britain	4829	4414	9944	3238	14773	7653
Ireland	557	417	2255	825	2812	1243
France	562	542	2128	386	2690	929
Norway	317	109	3958	1373	4275	1482
Italy	164	138	2324	753	2488	891
Spain	336	244	952	165	1288	409
Sweden	301	91	1690	367	1991	459
Holland	100	113	634	188	740	302
Russia	257	85	1720	210	1977	295
Denmark	191	92	980	150	1171	243
Austria	97	86	320	131	417	217
Greece	47	25	1013	194	1060	220
Belgium	53	79	11	5	64	84
Finland	47	9	750	201	797	211
Portugal	28	15	281	52	309	67
Hungary	12	7	132	61	144	68
Turkey (Europe)	14	6	285	47	299	54
Roumania	3	1	21	3	24	4
United States	2287	673	9633	1918	11920	2591
South America	166	79	578	173	744	253
Canada	272	76	3690	1000	3962	1077
Australia	465	139	917	208	1382	348
Other British Colonies	145	52	487	90	632	142
Spanish Colonies	95	42	427	50	522	93
Dutch Colonies	58	31	238	53	296	84
Other European possessions	26	21	192	31	218	52
Totals	11435	7599	45560	11885	56995	19485

The enormous preponderance of Great Britain is strikingly shown in this statement. It appears that reckoning, as before, one ton of steam tonnage as the equivalent of three tons of sailing tonnage, our own country can boast of 16½ millions of tons out of a total of 34 millions, being close on one-half of the whole. But it will further be observed that Great Britain has the advantage of possessing considerably larger ships, on an average. The total number of ships belonging to all nations is 56,995, and as their total is 19,485,000 tons, they would appear to average about 330 tons. The vessels belonging to the United Kingdom number 14,773, and aggregate 7,653,000 tons, or an average of 518 tons. In reference to steam shipping, it appears that the vessels of the British merchant marine average 914 tons, while those of the world generally only average 663 tons. This is a material gain to our own country, since large vessels are generally navigated with more economy than small ones.

The question of whether the future of British shipbuilding is likely to be equal to its past has been often put, and has been answered in many ways. The best test to which to bring the matter is probably that of the relative growth of shipbuilding and the commerce of the world generally. This inquiry, however, brings out some very curious results. The tonnage of the merchant navies of the world, at the present time, amounts to about 20 millions of tons, as already stated. Ten years ago the corresponding total was 19 millions of tons, or 5 per cent. less. But in this interval the commerce of the world, as measured by the entrances into and clearances from the ports of the ten principal ship-owning countries, has increased in a much more remarkable degree. The tonnage carried to and from the ten countries in question has advanced from 110 millions to 162½ millions of tons—a sure proof, one would think, that if our merchant marine has greatly increased, so also has the amount of work which it is called upon to perform. This is made clear in the following statistical statement, which shows the total entrances and clearances of sailing ships and steamers into and from the ports of Great Britain and Ireland, France, Russia, Germany, Holland, the United States, Belgium, Italy, Scandinavia, and Austria, during the period from 1873 to 1884:—

	Steamships. 1 = 1000 tons.	Sailing Ships. 1 = 1000 tons.	Totals. 1 = 1000 tons.
1873	59,706	46,876	106,582
1874	61,729	47,093	108,820
1875	64,916	45,184	110,000
1876	68,471	46,207	114,678
1877	72,935	46,753	119,688
1878	81,037	45,755	126,792
1879	87,045	46,659	133,704
1880	96,574	50,078	146,652
1881	99,298	45,230	144,528
1882	110,609	43,912	154,521
1883	123,738	40,100	163,838
1884	125,858	36,627	162,485

If these figures teach us any lesson, it is that of hope for the future. The rate at which we have provided ships for all the world has been growing, but so have also the necessities of the world's trade, taking one year with another; and as there appears to be as yet no limit to the expansion of trade, the demand for new tonnage must continue to increase.

Letters to the Editor.

ELECTRIC TRANSMISSION OF ENERGY.

To the Editor of "Industries."

Sir,—I have read with great interest your report on the trials made by a scientific committee with the transmission plant established between Kriegstetten and Solothurn, in Switzerland. The publication of these results, coming as it does at a time when electric transmission of energy, especially in its application to mining, is exciting public attention, your readers cannot fail to draw a comparison between what is done here and what is done abroad in this matter, the comparison being, I am afraid, much to the disadvantage of our own electricians. Data on transmission plant established in various mines in England have recently appeared in the scientific press. Among these is an account, published by you, of an electric mine pump in which the total efficiency for the indicated power to the water lifted is given as nearly 44½ per cent. In this plant an Immisch motor is employed for driving a pump in the mine. Now, taking the efficiency of the pump alone at 90 per cent., that of the reducing gear at 95 per cent., and that of the steam engine at 85 per cent., the total commercial efficiency between the power supplied to the dynamo on the surface and that obtained from the motor underground works out at 61 per cent. You do not give the distance of transmission; but from the general description, it would appear that this does not much exceed a quarter of a mile. Another account of a transmission plant was given by Mr. Frank Brain in a paper read before the South Wales Institute of Engineers, and I may incidentally mention that Mr. Brain, in a recent letter to you, claims this to be the largest electrical plant at present existing in England. The distance of transmission appears to be slightly over a mile. In this case the dynamo on the surface and the motor underground are both made by Messrs. Elwell-Parker. The power of the engine is given as 29·49 i.h.p., and the work done in water lifted as 10·36 h.p., showing an over-all efficiency of 35 per cent. Making the same allowance as before, for the loss of power in the engine, gearing, and pumps, the actual commercial efficiency of the transmission plant comes out at less than 50 per cent. In both cases you will see that the result falls far below that obtained by the Oerlikon firm in transmitting over a very much greater distance. Now, why should this be so? I am quite satisfied that Messrs. Immisch & Co. and Messrs. Elwell-Parker can build dynamos and motors equally efficient with those turned out by the Swiss firm; but yet in practical working the latter are far away ahead of their English rivals. I believe the true reason of this success is not that the Swiss firm know better than our electricians how to build dynamos and motors; but knowing it equally well, have the courage of their opinion, and resolutely set their face against the cheese-paring policy under which our own electricians try to outshine each other in the matter of obtaining enormous power from very little weight. If you want an efficient dynamo or motor you must make it big enough and heavy enough to do its work.

Now, what is the English practice and the Continental practice in this respect. We have recently heard something about a new dynamo, made by Messrs. Paris & Scott, which weighs only 80lb. per horse power output, and a modification has even been promised which will weigh only 30lb. per horse power output. An Immisch motor was shown a few weeks ago at the Institution of Civil Engineers, which, weighing 6cwt., could develop 10 h.p.; and the motor fitted by Messrs. Elwell-Parker to the electric tram car, which was tried last week, is said to weigh 16cwt. and to develop 25 h.p., being at the rate of 72lb. per horse power. I do not say that the desire to reduce weight is in itself objectionable, but I maintain that such reduction becomes objectionable if it involves a sacrifice of efficiency. Hitherto I have always been told that a substantial, well designed dynamo will at a moderate speed have an output of about 1 h.p. for every 100lb. of dead weight, and the Edison-Hopkinson machines, than which there are no others having an equally high efficiency, do even considerably exceed this margin of weight. So far the English practice. Now let us examine the Swiss practice. The type of machine employed must be called a light type, as compared with the Edison-Hopkinson dynamo, and yet you give in your report of last week the weight of a 20 h.p. machine as 72cwt. Speaking generally, we may therefore assume that these machines are much heavier than English makers would have constructed them, and I think we have to look to this fact as the reason why the efficiency of the plant is so unprecedentedly high. It has of late become quite a mania with English electricians to cut down the dead weight of their machines to an absurdly low point, and I feel confident that

Digitized by Google

unless they abandon this policy, and build heavy and substantial machines, they will not be able to show results even approaching those you published last week.

Yours, &c.,

London, 9th January, 1888. ERG.

ELECTRIC LIGHTING FROM CENTRAL STATIONS.

To the Editor of "Industries."

SIR,—My directors have noticed your report of Mr. J. R. Williamson's paper in your issues of the 16th and 23rd ult. on "Central Station Electric Lighting," and there are a few explanations which I should like to make on this paper, if you would kindly allow me the space, viz.: The Grosvenor Gallery installation was commenced under the supervision of the engineers of the National Company for the Distribution of Electricity by Secondary Generators, Limited. Its subsequent working under Mr. Ferranti is the subject of litigation. The Lowrie Hall converter, which is a most efficient instrument, is worked under license from this company, who are the proprietors of the Goulard-Gibbs patents.

Yours, &c.,

J. E. PICKERING,

London, 7th January, 1888. Secretary.

TRIPLE EXPANSION ENGINES FOR TEXTILE FACTORIES.

To the Editor of "Industries."

SIR,—Can any of your readers inform me whether any makers have as yet applied the system of triple expansion to stationary engines for textile factories, which has been so largely adopted in marine engines, and with such beneficial results?

Yours, &c.,

Halifax, 8th January, 1888. H.

RAILWAY RATES.

To the Editor of "Industries."

SIR,—The letters on the above subject which have appeared in your journal during the last few weeks show that the public generally have a grievance against the railway companies, for where one person complains publicly, there are a dozen who do so privately. I have had from time to time my share of unpleasantness with some of the railway companies, of which I will give an example presently. I notice that at the monthly meeting of the Council of the Railway and Canal Traders' Association held this week, the secretary reported "that the average number of complaints as to excessive and unfair railway rates had been exceeded during the past month." What irony! To think that complaints must be as regular as clockwork, and commented upon if they exceed the average. Poor, long suffering British public! A resolution was unanimously carried at the same meeting, "That in view of the provisions contained in the Railway Bills of 1886 and 1887, with respect to preferential railway rates in favour of foreign produce, it is urgent that a test case involving this point be fought; and that steps be at once taken to raise a special fund for the purpose of insuring the initiation of proceedings prior to the introduction of the promised Railway Bill during the ensuing session, and their due prosecution subsequently. One point has not hitherto been noticed by your correspondents, and that is the effect of rivalry and personal jealousy between the chairmen and other officers of competing lines. This, in my opinion, prevents concessions to the public. One line will not work with another, and a return railway ticket issued by one company is not available for the return journey by the competing line. To give a case in point, the price of a return ticket from Peckham Rye to London Bridge is the same as to Victoria and to Ludgate Hill. I may return from either London Bridge or Victoria with a ticket taken to either place, these termini being on the same line of railway; but I cannot return from Ludgate Hill, which lies between the two, because the line is owned by a rival company. Is this not very absurd? If these two railways were in the hands of the Government, or if the companies were friendly disposed towards the public and each other, I should be able to travel from either of the three stations named.

I see an effort is being made to secure amicable working between the Southern lines, and the effect is a rise in their stocks, viz., 1¾ per cent. in the London, Brighton, and South Coast line, and ⅞ per cent. in the South-Eastern. It is doubtful, however, whether the reform can be carried out, as the chairman of the Brighton Railway has addressed a letter to the syndicate which has the object in view, stating that he has no difficulty in carrying out plans for peace and harmony with either the Chatham or the South-Western Companies; but Sir Edward Watkin has revived claims which entail disputes with the Brighton Company, and, in short, he does not see his way to cordial working with the South-Eastern under Sir Edward's presidency. Mr. Forbes, of the Chatham Railway, writes on "the waste of money and power going on under the present armed truce between at least one of the companies and the other two." Meanwhile a record of opinion is being signed by some of the shareholders of the South-Eastern Railway, stating that "no further time should be permitted to elapse before a vigorous effort is made to terminate the long standing friction, restlessness, and hostility manifested by this company towards the London, Brighton, and South Coast Railway and the London, Chatham, and Dover Railway Companies, and that in the mutual interests of the three Companies it is essential an arrangement be arrived at, based upon the principle of a working union, and having for its object the utilisation to the full of the unequalled resources of the three Southern railway systems, thereby yielding to the public demand." The record of opinion concludes by intimating that another chairman of the South-Eastern is desirable. Thus the game goes on, and the public are sacrificed to the chairmen. Is not the sectional character of the whole railway system ridiculous? My opinion is that railways should exist for the public good, and that anything which stands in the way should be removed by legislation. The principal grievances of the railway system, as conducted at present, are the differential rates, the excessive rates, the want of uniformity of rates amongst the various companies, the great number of classifications, and the diversion of traffic from its natural channel by canvassers.

Mr. Jeans, in his evidence before the House of Commons, stated that the average cost for all England of the railway charges for the raw materials used to produce a ton of pig iron was 5s. per ton for fuel, 4s. 11½d. per ton for iron ore, and 11½d. for limestone; this equalled 16 to 19 per cent. on the selling price of the iron, and as 7 to 8 million tons of pig iron were made annually it represented a very serious item. Comparing these prices with those paid abroad, they stand thus:—

	Average cost for England. Per ton per mile.	Average cost for France, Belgium, Germany, and the United States. Per ton per mile.
Iron ore	1·19d.	0·55d.
Pig iron	1·2d.	0·75d.
Manufactured iron	1·63d.	0·78d.
Steel rails	1·55d.	0·78d.

Thus it is seen that the foreign rates are considerably less than our own, and the effect is to weigh very heavily against the English manufacturer in the competition to which he is subject. The difference is about 5s. 8d. per ton against this country.

Besides the higher rates, the trader has to fight against the companies charging more than the legal rates. Two instances of this have recently been made public, and the curious thing about them is that the two companies declined to fight, preferring the payment of claims into Court rather than run the risk of losing their cases. The facts are as follow: The London and North-Western Railway Company charged 8s. 4d. per ton for conveying iron from Birmingham to a town in Staffordshire, 9½ miles distant; this, it was contended, was 5s. 4d. per ton too much, or 64 per cent. overcharge. In the second case, the Great Western Railway Company was the culprit, by charging 7s. 4d. per ton for conveying iron from Birmingham to Warwick, 22 miles distant; this, it was contended, was 3s. per ton too much, or 41 per cent. overcharge. The manufacturer refused to pay the charges at first, but as the companies refused to carry the iron the amounts were paid under protest. Upon being sued in Court for the excess, the claims were met by the refunding of the overcharges. These cases speak volumes, and are no doubt typical of what takes place in other parts of the country where manufacturers are more pliable.

Few people know enough of the proper rates to take a case into Court, but that overcharges are common I feel convinced. An instance occurred to myself only a few weeks ago which illustrates the principle on a small scale. I received a parcel from Derby, for which 2s. 4d. was demanded. This I paid; but upon my inquiring at the station the reason of so high a charge some ten or twelve days later, I was informed that a mistake had been made, and 3d. was refunded me. I am further informed that 4d. is for delivery to my house, which lies beyond the free delivery distance of a mile. I meekly acquiesce, and look in the published table of rates and find the rate should be 1s. 11d., and this amount, with 4d. for delivery, makes 2s. 3d. Why 3d. was returned to me out of 2s. 4d. is a mystery. I merely give this as an instance of the uncertain charges which are made for small articles as well as for large ones. If parcels are sent by post there is a fixed definite charge, with no extras for delivery outside a limited radius. We want the railway system of rates to be as simple as the Post Office system, and in my opinion the Railway Commissioners should fix the rates for parcels and goods as well as the fares for passengers, leaving the railway companies to carry whatever is presented to them at what speed they like, and with regard to passengers, in what comfort they like. The public would soon choose the lines which did the work the best. The present system of rates and charges gives room for peculation on the part of railway servants, because few people know the exact charge for a parcel by railway, and the temptations are such as no railway servant should be exposed to.

EDDY CURRENTS IN ARMATURE WIRES.

To the Editor of "Industries."

SIR,—In the construction of large dynamos with heavy wire or bars of rectangular section, the eddy currents in the armature conductors become a factor for serious consideration, and render it necessary to introduce special means to reduce them. It is well known that these eddy currents form their circuit throughout the length of the portion of armature wire presented to the field magnets, as shown in Fig. 1, and it may be asserted, from

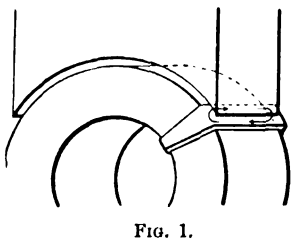

FIG. 1.

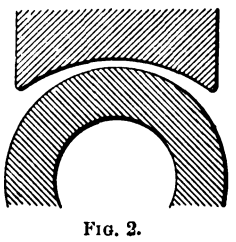

FIG. 2.

the result of experiment, that they are only generated when approaching and leaving the field. The strength or amount of eddy current depends on the speed with which the wire moves into and out of the magnetic field. These objectionable currents can be greatly reduced by shaping the magnet poles as in Fig. 2, so that the wire gradually enters and leaves the field. Cutting the corners in this way increases the efficiency of the machine rather than reduces it, for what is lost in extent of field is more than regained by the reduction of the eddy currents. The extent to which the corners of the pole pieces must be removed in this way depends on the dimensions of the armature conductor. If the wire is very broad, the poles must be cut so as to make the tangent line longer. The shape of the conductor, and its position relative to the armature core and the field magnets, have a greater bearing on the reduction of eddy currents than the shape of the field magnets. Rectangular wire, if wound flat on the core, presents the most favourable conditions for eddy currents, the reason being that electricity is generated in the edge of the wire that enters the field first, and closes its circuit through the part still to enter, as shown in Fig. 1. If the rectangular wire is wound edgeways on to the core, the eddy currents generated by the pole could only complete the circuit through the opposite side of the rectangle in opposition to the current generated by the core. What small amount of eddy current is generated in the top edge of the bar can be stopped by rounding this edge and shaping the poles as described. Round wire of any diameter is nearly proof against eddy currents if the machine be otherwise correctly proportioned. This latter point is necessary with all shapes of wire. It is probable that shaping the poles as shown in Fig. 2 would prevent eddy currents in the iron when toothed armature cores are used.

Yours, &c.,

J. D. F. ANDREWS.

THE THOMAS-GILCHRIST PROCESS.—The progress made in this process during the twelve months ending 31st October, 1887, is shown by the following: The total make of steel and ingot iron from phosphoric pig during this period amounts to 1,702,252 tons, being an increase over the make for the previous twelve months of about 388,621 tons. It will be noticed from the annexed table, that of this make no fewer than 1,222,732 tons were ingot iron containing under ·17 per cent. of carbon. The makes of the various countries for the twelve months ending 31st October, 1886, and 31st October, 1887, respectively, are as follow:—

	1886.		1887.	
	Total tons.	With carbon under ·17 %.	Total tons.	With carbon under ·17 %.
England	258,466	161,908	364,526	233,358
Germany, Luxemburg, and Austria	883,859	651,523	1,102,496	826,600
France	122,711	77,141	174,271	123,049
Belgium and other countries	48,595	36,712	60,959	39,716
Totals	1,313,631	927,284	1,702,252	1,222,732

WE have received a copy of the first number of "Examples of Antique Furniture," by W. S. Ogden, of Manchester. This work will be issued in twenty monthly parts, and each number will contain six plates illustrative of old English wood and metal work. Judging by the first number, we should think that the complete work will constitute an excellent hand book.

"A MODEL OF EXCELLENCE."—Our readers may be interested to learn that the model of the compound locomotive "Dreadnought," exhibited by Mr. F. W. Webb, locomotive superintendent of the London and North-Western Railway Company, at the late Manchester Exhibition, earned during its stay there the handsome sum of £127. 7s. 3d. This amount has been generously distributed by Mr. Webb amongst several hospitals and charitable institutions. From May to November the engine made 183,396 revolutions, equal to a linear distance of eighty-three miles. The earnings averaged £1. 10s. 8d. per mile, and, looking at this result, we may well advise our full-sized locomotives to *go* and do likewise.

STACKING COAL.—A very interesting paper on a new coal conveyer was read by Mr. James M. Dodge, at the recent meeting of the American Society of Mechanical Engineers. In the old system of stacking coal by hand the cost is about 1s. 3d. per ton, whilst the size of the stacks are necessarily limited. Mechanical stacking machines have been erected at the wharfs of the Philadelphia and Reading Railroad Company at Port Richmond, whereby the cost of stacking is reduced to a fraction of the amount given for hand labour, whilst the size of the stacks can be increased to as much as 20,000 tons. These mechanical stacking machines or conveyers consist of an endless chain about 150ft. long, and provided with scrapers 8in. by 20in. The chain is suspended in an inclined position by two sprocket wheels, one near the ground and below the dumping platform, where the coal is shot from the trucks, and the other attached to a pole which is steadied by guy ropes. The returning and upper part of the chain is supported by an idle pulley suspended from guys. The coal as it falls into the dump is pushed up by the scrapers, and thus forms a conical pile of about 75ft. in width at the base. In some cases the lower sprocket wheel is shifted from time to time, so as to extend the size of the pile laterally. When a pile is completed, the chain, the sprocket wheels, and guy ropes are removed to another place for the formation of a new pile, and the only portion of the plant left standing is the pole. A similar apparatus is used for re-loading the coal into cars after it has been stacked. A conveyer is used which is so constructed that it may be used sideways towards the base of the pile and kept running continuously, while it automatically attacks and conveys the coal towards the trestle from which it was originally dumped. At that spot there is a second conveyer which lifts the coal into a hopper, from which it is shot into the car. The re-loading conveyor is so constructed that it can be swung to the right or left so as to operate on either side.

ELECTRICAL PROGRESS IN 1887.

The year that has just passed has not brought to light many startling novelties in the way of the application of electricity to industrial purposes, although considerable progress in matters of detail has been made. Generally speaking, the progress was comparable to that made in other branches of engineering; that is to say, known methods of utilising this particular force of nature have been extended, the size of machines and apparatus has been increased, constructive details have been improved, and a few new inventions have been made. The laws which govern the construction and working of dynamos are now so well and so generally understood, that it is possible to predict from an examination of the design of a dynamo what its capabilities will be when actually constructed, and the introduction of so-called new types is, therefore, not a matter involving any great risk of failure. The novelty in the type is, however, generally confined to the shape of the field magnets and the number and position of exciting coils. Engineers have gradually come to the conclusion that there is very little difference in the effectiveness of different arrangements, provided always that the cross section throughout the magnetic circuit be ample, and there be sufficient space on the magnet cores to wind the exciting coils on. Thus, whilst some of the earlier Gramme, Edison, Weston, and other machines had a large number of field magnet limbs, and a similar number of exciting coils, in later machines, such as the Siemens and Crompton, this number was reduced to four. The number was further reduced to three in direct driven dynamos with inverted poles, and then to two both for direct and belt driven dynamos, which appears to be the usual practice with most English makers. At the beginning of the year it was thought that with a two-coil magnet the greatest possible simplicity of construction had at last been reached. This was, however, not the case, and recently some firms, notably Messrs. Goolden & Co., and Mr. R. Kennedy, have produced machines with only one exciting coil on the field magnet. The new design is, however, hardly likely to come into general favour, because the total weight of the machine must be considerably greater than that of a two limbed single horseshoe machine, which is again greater than a two limbed or four limbed double horseshoe machine of equal output. The type of dynamo at present most in favour for ship lighting, and especially for Admiralty work, is the two limbed single horseshoe inverted pattern with drum armature, although some disc machines have also been installed. The size of dynamos required by the Admiralty during the past year was generally larger than in previous years. In all, thirty-eight sets have been required for war vessels, of which four were specified to have an output of 400 ampères, twelve were specified to give a maximum of 300 ampères, and the remaining 200 ampères, all at 80 volts pressure. The conditions under which firms were invited to tender for this Admiralty work were remarkable, and a proof that the construction of dynamos was regarded as an exact science. Not only was the speed strictly limited, as on previous occasions, but the weight of steam consumed per hour, per electrical horse power output, had to be stated by the contractor for each particular machine, and if exceeded on trial a fine was imposed. The Admiralty also stipulated that the temperature of any part of the machine should, after a prolonged run, not rise above a certain, and as most electricians thought, absurdly low limit. The fact that under such stringent conditions contractors cared to tender, and that the work was executed to the satisfaction of the Admiralty, is exceedingly creditable to our electrical engineers.

A large number of merchant vessels has been fitted with electric light plant, partly for internal lighting by glow lamps, and partly with arc lights to be used when coaling or taking in or discharging cargo at night. A few steamers have also been fitted with search lights, to facilitate canal navigation at night; but this use of electricity has not become so general as appeared probable at the beginning of the year, when night passages were permitted on the Suez Canal. Most ship lighting dynamos now are either direct driven or are connected with the engine by means of friction wheels, belt and rope gear being but seldom used. There has been no startling novelty in ship lighting plant, except perhaps Parsons' Turbo Electric Generator, which appears to find favour with shipowners and engineers in the North. This combined engine and dynamo, which was first shown at the Inventions Exhibition in London, in 1885, has since then been steadily improved by the inventor, and the splendid display and excellent performance of these machines at the Newcastle Exhibition last summer must have convinced visitors that what some years ago had seemed little better than a clever scientific toy had now been developed into a practical machine, capable of doing as hard work as any other modern dynamo, and with fair economy. The generators exhibited at Newcastle consumed only about 60lb. of steam per electrical horse power output per hour, but in the latest compound generators this consumption has been yet materially reduced. Briefly described, the generator consists of a double set of parallel-flow turbines, the steam entering in the middle and exhausting at both ends. To provide for the expansion of the steam whilst doing work, the angle between the blades (both in the barrel, which in an ordinary turbine corresponds to the wheel, and in the casing which similarly corresponds to the guide) and the plane of rotation becomes greater towards the ends; but as it was found that this device by itself was not sufficient to allow full scope to the expanding power of high pressure steam, two larger barrels were added at the ends of the original barrel, and by thus compounding the engine a greater range of expansion was obtained. Recently, Mr. Parsons has added a third pair of barrels, giving his generator a triple expansion. At the very high speed of from 8000 to 10,000 revolutions per minute, the change in the magnetisation of every particle of iron in the armature core takes place very much more rapidly than in ordinary dynamos, and it is for this reason that the usual rules of construction had to be somewhat modified in this case. At ordinary speeds, the more intensely the core can be magnetised the better, and most recent improvements have for their object to increase the strength of the field. With the turbo generator, a very strong field would, however, be objectionable, as tending to heat the iron core of the dynamo by hysteresis or molecular friction, and it is for this reason that Mr. Parsons employs very small field magnets of cast iron, and feebly excited. Owing, however, to the high speed, the output of his machines is nevertheless very much greater than that of ordinary dynamos having the same weight. The small weight and high efficiency of the Parsons dynamo, as well as its perfect automatic lubrication and its freedom from vibration, should make this type of machine particularly suitable for continuous current transformers.

As regards this class of apparatus, a great deal has been written during the year, but very little has been accomplished, and the transformer shown by Messrs. Paris and Scott, at the close of the Newcastle Exhibition, is almost the only machine which has as yet come before the public in this country. In Austria, Messrs. Jehl & Rupp seem to have worked in this field, but with what practical success we are unable to say. It is true that one of our contemporaries has from time to time published accounts of some wonderful machines invented by these gentlemen; but whether these existed on paper only, or were in actual practical use, has never been distinctly stated, and until that point is cleared up we incline to the belief that the Jehl & Rupp systems are merely projects, or at best experiments on a small scale. In this connection it is necessary to mention the work done by Mr. Edison, who already in 1881 began to take out patents for transformers or motor generators. His earlier machines consisted merely of a series of stationary induction coils connected with two commutators, which were revolved by a small electromotor; but in later designs he mounted the coils upon a continuous ring-shaped core and revolved this with its two commutators, suitable brushes making connection with the primary and secondary circuits. Later still he surrounded the induction ring with a stationary soft iron shield, and according to an American electrical paper he seems at present to be engaged in putting down a station at Llewellyn Park, near New York, for lighting his own and some neighbouring residences by means of continuous current transformers.

In central station work very little progress was made during the past year in England; but in America, and on the Continent, electric lighting from central stations has developed with marvellous rapidity. The Thomson-Houston Company, of Lynn, Massachusetts, have, during the year, practically doubled the capacity of their works, in order to satify the enormous demand for electric lighting plant for all parts of the country. The Westinghouse Company, who have adopted the alternate current system, have likewise been very busy with the erection of central stations; and as regards other companies, such as the Edison, the Western, the United States Electric Lighting Company, and others, they have all been actively engaged on central station work, and hardly a week has passed without news reaching us of new stations being started in American towns. On the Continent, the stations at Rome, Milan, Lucerne, and Berlin have been enlarged, and many of the provincial towns in Germany have started new stations. Compared with these achievements, our own central station work appears quite insignificant. The most important, perhaps, is that at the Grosvenor Gallery, in Bond-street, London, which has, during the year, considerably increased its area of supply. The small central station at Kensington Court, which was started in the beginning of the year, and which we described in our issue of the 18th February, has been successfully running ever since, and towards the end of the year a central station at Leamington was also successfully started. The Eastbourne installation was extended by the addition of a very fine compound engine and new dynamos, whilst the Brighton installation has also been increased. Originally only Brush dynamos, and Brush arc lamps, with here and there a group of incandescent lamps, were in use at the latter installation. Lately, however, a large alternate current machine has been erected for incandescent lighting in various parts of the town.

Some progress has also been made in alternate current machines and transformers, although the inventors and manufacturers have for obvious reasons preferred to keep back information in reference to these matters. Until about a year ago, the only alternate current machines available were those of Siemens, Ferranti, Elwell-Parker, and Gordon, though the latter was, properly speaking, not in the market, being only built for the immediate requirements of the company owning the patents. Within the year, however, several alternate current machines have been invented and successfully tried; and it is highly probable that the near future will see a considerable development in this branch of electrical engineering. The same is the case with transformers. At present, that of Mr. Ferranti is very extensively used, but Messrs. Lowrie & Hall have come into the field with a very neat design which is doing good work at Eastbourne, and Messrs. Gaulard & Gibbs are also bringing out a new type, resembling the Zipernowsky transformer in the relative position of the winding and core, though with this difference, that the latter, instead of consisting of iron wire, is formed of rectangular iron stampings.

In the application of electricity to motive power purposes, English engineers have not been left behind their American and Continental colleagues to the same extent as is unfortunately the case with central station lighting. Some good work has been done in electric transmission of energy and electric propulsion. Messrs. Immisch & Co., who make a specialty of electromotors, have put up several plants at mines for transmitting power from the surface to the workings, for pumping and other purposes, and have also sent transmission plant to several places in the Colonies. In connection with the Electric Traction Syndicate, they have equipped some tram cars with the necessary electrical apparatus, and the trials, which we described in detail in our issue of 29th July, proved very successful. Very good work was also done during the year by the Elieson Company, on the North Metropolitan Tramway, and the fact that notwithstanding the heavy and somewhat cumbersome machinery employed in this special "system" electric traction has proved perfectly reliable and successful, speaks well for the latent capabilities of propulsion by storage batteries. The actual cost per car mile has not been published. Mr. Elieson's original estimate was 4½d., though this has probably been exceeded. But even if the cost should amount to as much as 5½d., or even 6d. per car mile, tramway companies would find electric traction more economical than horse traction. It is easy enough to compete against animal power; but is there any chance of electricity being able to compete against steam power? According to Lord Bury, the answer must be in the affirmative, for he told the Institution of Civil Engineers, during the discussion on Dr. E. Hopkinson's paper on the Newry and Bessbrook electric tramway, that his syndicate is about to run electrically propelled trains on the Metropolitan Railway. In America, electric railways and tramways have during the year been also largely developed. As yet, most of the lines are worked on the direct supply system; but storage cars are now beginning to come into favour, and both Julien and Reckenzaun cars have been introduced. The latter are being built by Messrs. Wharton & Co., of Philadelphia, and about six hundred of these cars are now on order for different American tramway companies. The plant for transmitting power from Kriegstetten to Solothurn, in Switzerland, which was erected by the Oerlikon engineering works in the beginning of the year, has since then worked without a hitch, and recent trials, which we published in our issue of the 6th inst., made by a committee of scientific men, have shown that about 75 per cent. of the power at the generating station is actually available at the motor station, the distance over which the transmission takes place being close upon five miles. The very neat and ingenious application of electricity for operating portable machine tools, which was devised by Mr. F. J. Rowan, and greatly perfected during the year, deserves special mention. These tools are specially intended for the drilling, riveting, and caulking which must be done *in situ* on vessels under construction, and for which hand labour only has hitherto been available. A full description of these tools will be found in our issue of the 5th of last August.

In electrical measuring instruments the past year has brought but few novelties, although the want of good, cheap, and reliable instruments is fully recognised. Some years ago Sir W. Thompson, when lecturing at the Institution of Civil Engineers on absolute measurements, remarked that it is easier to ascertain the exact resistance of a wire than to ascertain its exact length, the object of the remark being to show of what a high degree of accuracy electric measurements are capable. It is no

Digitized by Google

COMPOUND STEAM TURBINES.

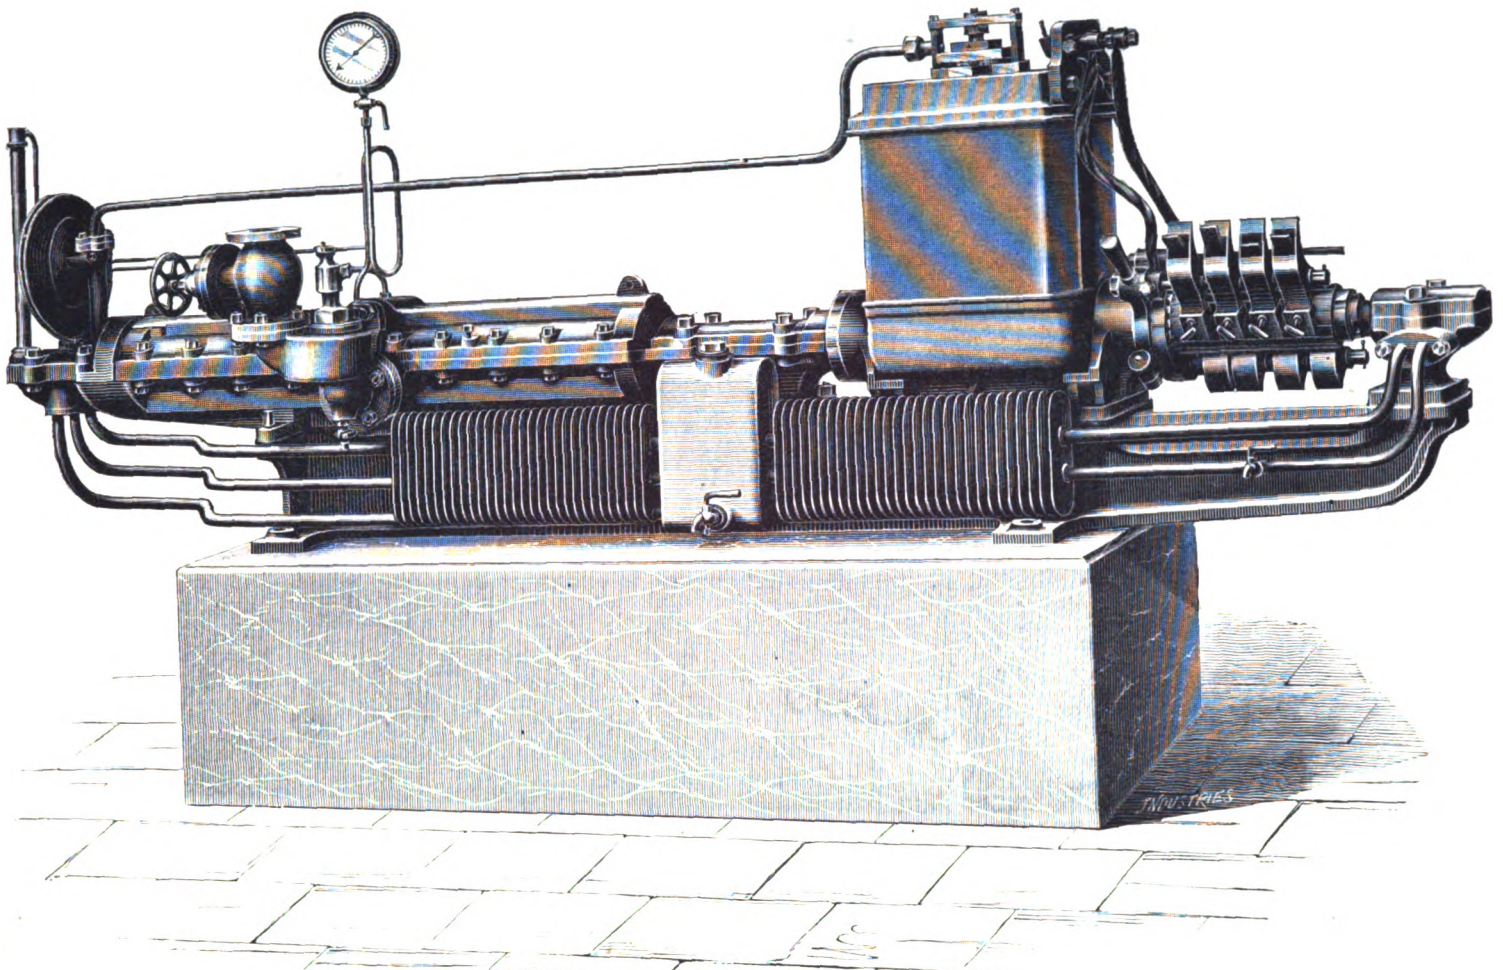

Fig. 1.

doubt quite easy to measure electric quantities with very high accuracy when the operation is carried out in the laboratory, and by the aid of very perfect instruments; but for ordinary commercial measurements of electric quantities, the apparatus generally supplied is not by any means of a very high degree of accuracy, whilst the circumstances under which the measurements must be made are generally speaking inimical to very exact work. Notwithstanding the large number of electric measuring instruments introduced within the last few years, there is as yet not one commercial instrument in the market which can be absolutely relied upon under all conditions. In making this statement we do not wish to imply that if proper care is taken, and the previous history of the instrument is accurately known, its indications cannot be relied upon; but it is seldom possible to take sufficient care of instruments, and generally quite impossible to determine by mere inspection whether the instrument has been damaged at some previous time. With an ordinary 2ft. rule we can be absolutely certain from mere inspection that it has not received an injury affecting its accuracy. With the ordinary scale and weights this is also generally possible; but when we come to electrical measuring instruments it is quite impossible, without very careful and detailed examination, to ascertain whether the instrument is in a trustworthy condition; and although Sir William Thomson's statement that a resistance can be measured with greater accuracy than a length is theoretically true, practically the reverse is the case, simple mechanical measurements of lengths and weights being possible with far greater certainty and accuracy than electrical measurements of potential and current.

The principal aim of all the more recent inventors or designers of electrical measuring instruments has been to produce types in which the possibility of accidental injury or loss of calibration is reduced to a minimum. The original form of ammeters or voltmeters where permanent magnets were used has been superseded by improved designs containing either electromagnets or weights or springs as a counteracting force, and a new class of instruments depending upon the heating effect of an electric current in a fine wire has also largely come into use.

Towards the end of the year Dr. Fleming brought out a new spring balanced voltmeter and ammeter, whilst Professors Ayrton and Perry introduced a very ingenious modification of the Cardew voltmeter, whereby the size of this instrument has been considerably reduced, and at the same time it has been made available for reading small potential differences. As regards integrating meters, Dr. Aron has further improved his clockmeter, making it self starting and self stopping, and also introducing a modification whereby it becomes applicable to the three-wire system; Messrs. Chamberlain & Hookham have brought out a new meter, which is in use at the Leamington installation, and Professor Forbes has devised the very beautiful meter depending on its action upon the movement of a column of air heated by a coil through which the current passes. Up to the present this is the only meter which gives absolutely the same reading whether the current be continuous or alternating.

COMPOUND STEAM TURBINES.*

We shall begin by describing water turbines and some of their performances, together with the necessary conditions for economy in motors of this class. We shall then describe the compound steam turbine, and draw a parallel between it and the water turbine, showing by the help of the latter that the conditions for high economy are fulfilled in the compound steam turbine. We shall then give figures to show what the theoretical economy of the compound steam turbine should be, and then deal with the dynamo and its combination with the steam turbine. Water turbines have been for many years in extensive use in Europe and America, and have, after many experiments, been brought to a very high degree of perfection, as is shown by the numerous tests that have been made to ascertain their actual efficiency. Perhaps the most carefully arranged and the most exhaustive of these experiments are those made by Mr. James B. Francis on the Tremont turbine at Lowell, Massachusetts. The result showed that the horse power indicated on the dynamometer attached to the shaft amounted in some cases to 79·3 per cent. of the total power of the water, whilst those made on another turbine of still more improved design gave an efficiency of 88 per cent. The theory of the turbine has been thoroughly dealt with and understood, and theoretical reasoning leads also to the conclusion that such a high efficiency in a turbine is quite possible provided that certain rules are adhered to in the design, and provided also that certain essential conditions as to the flow of water are provided for. All water turbines consist essentially of a set of fixed vanes, called guide blades, and a set of moving vanes called the wheel; the former guide the water towards the direction of motion of the latter. The important conditions for economical working being that the shape of the blades and the velocity of the wheel shall be so arranged that there shall be no shock or sudden change of the velocity of the water in passing from the guide blades to the moving blades, and also that as the velocity or energy of the water on leaving the wheel is lost it shall be reduced to the utmost extent by the formation of the blades. This leads us to inquire what has been found to be the best velocity of wheel to meet these conditions. In Mr. J. B. Francis' experiments, page 33, we find—

Experiment.	Per cent. of Velocity of wheel, of Velocity due to head.	Efficiency.
42	30	67
41	39	72
36	50	78
30	63	79·3

We have here then the speed which gives the maximum efficiency, and a measure of the diminution of efficiency corresponding to a reduced speed. The essential conditions for high efficiency are, as we have said, absence of shock and low residual velocity. These conditions, in the case of the water turbine, can be better obtained in the types called the outward or inward flow than in the parallel flow, for the large volume of water to be dealt with necessitates long blades of double curvature for the last mentioned type; these are objectionable, while it is more difficult to minimise the residual velocity of the water leaving the wheel. Principally these reasons have led to the more general adoption of the outward or inward flow types than of the parallel flow. After careful consideration, however, the parallel flow type seemed more suitable to the compound steam turbine, and has been accordingly adopted. Fig. 5 shows the arrangement of ninety complete turbines, forty-five lying on each side of the central steam inlet. The guide blades R are cut on the internal periphery of brass rings, which are afterwards cut in halves and held in the top and bottom halves of the cylinder by feathers; the moving blades S are cut on the periphery of brass rings, which are afterwards threaded and feathered on to the steel shaft, and retained there by the end rings, which form nuts screwed on to the spindle. The whole of this spindle with its rings rotate together in bearings, shown in enlarged section, Fig. 2. Steam entering at the pipe O flows all round the spindle and passes along right and left, first through the guide blades R, by which it is thrown on to the moving blades S, then back on to the next guide blades, and so on through the whole series on each hand, and escapes by the passages P at each end of the cylinder connected to the exhaust pipe at the back of cylinder. The bearings, Fig. 2, consist of a brass bush, on which is threaded an arrangement of washers, each successive washer alternately fitting to the bush and the block, while being

Industries.

alternately $\frac{1}{32}$nd smaller than the block outside, and $\frac{1}{32}$nd larger than the bush in the hole. One broad washer at the end holds the bearings central. These washers are pressed together by a spiral spring N and nut, and, by friction against each other, steady or damp any vibration in the spindle that may be set up by want of balance or other causes at the high rate of speed that is necessary for economical working. The bearings are oiled by a small screw propeller I attached to the shaft. The oil in the drain pipes D and F, and the oil tank D, lies at a lower level than the screw; but the suction of the fan K raises it up into the stand pipe H over and around the screw, which grips it, and circulates it along the pipes to the bearings. The course of the oil is as follows: The oil is forced by the propeller I and oils the bearing A (Fig. 1), the greater part passes along the pipe E to the end bearing C, some after oiling the bearing C drains back by the pipe F to the reservoir D, the remaining oil passes along through the armature spindle, oils the bearings B, and drains into the reservoir D, from which the oil is again drawn along the pipe G into the stand pipe H by the suction of the fan K. The suction of the fan is also communicated to the diaphragm L, and forms, with it and the spring M, the principal part of the governor which actuates the throttle valve V. Fig. 3 is the electrical control governor, which will be further described in connection with the dynamo. It acts directly upon the controlling diaphragm L by admitting or exhausting a quantity of air, and thus exercises a controlling influence upon it. For small differences of pressure the velocity of air or steam passing through orifices or short tubes is given by the same formula as that for water. The heads of pressure have to be calculated in each case in terms of the respective fluids, and for small differences of pressure the velocity of efflux is the same for the same head in all cases. This has been recognised as a fundamental principle; it has also been verified in some of the cases we are going to consider by actual measurements. We now proceed to consider the action and condition of the steam as it passes through the successive turbines; but, before doing so, it will be necessary to go into some calculation in order to form a correct basis to start from. The velocity of efflux of steam flowing from a vessel at 15·6lb. per square inch absolute pressure through an orifice into one at 15lb. absolute pressure is 366ft. per second, the drop of pressure of ·6lb. corresponding to a diminution of volume of 4 per cent. in the opposite direction. We must now suppose that the turbines are so proportioned and the blades so diminished in size that each one nearer the steam inlet O has 4 per cent. less blade area or capacity than the preceding one all the way from each of the exhaust ends up to the centre. If we work this out we find that after forty-five turbines the pressure will be about 69lb. above

Digitized by Google

the pressure at the inlet. The steam will have followed some curve of temperature and volume very near the adiabatic; but on the isothermal side of it, the velocity of flow will be slightly greater near the inlet, in consequence of the increased temperature. The steam enters from the steam pipe at 69lb. pressure, it passes through the first turbine, consisting of a ring of guide blades and then a ring of moving blades, and falls 2·65lb. in pressure; the velocity due to this fall in pressure is 386ft. per second, its volume increases by 3·85 per cent. of its original volume, it passes the second turbine, falls 2·55lb., and again increases its volume in the same ratio, and so on till it reaches the last turbine, where its pressure is 15·6lb. before entering and 15·0lb. on leaving it to flow into the exhaust pipe. The velocity due to the last drop is 366ft. per second. The steam has, therefore, nearly the same velocity of flow for all the turbines; in other words, the error in assuming the velocity due to the head to be 376ft. per second throughout does not exceed 3 per cent. The velocity of the wheels at 9200 revolutions per minute is 150ft. per second, or 39·9 per cent., of the mean velocity due to the head throughout the turbines. On comparing this ratio of velocity of wheel to velocity of flow with that of the Tremont water turbine, we find a corresponding efficiency of a little over 72 per cent. Hence in the compound turbine we are describing, the velocity of the blades is sufficient to secure a very high return of useful effect. We may therefore assume that if the blades be equally well shaped in the steam turbine as in the water turbine, and that the clearances be kept small and the steam be dry, then each turbine of the set will give an efficiency of at least 72·5 per cent. We say at least, because as each turbine discharges without check into the next, the residual energy after leaving the moving blades is not lost, as it is in the case of the water turbine we are considering (it amounts to from 3 to 5 per cent. of the energy), but continues into the next guide blades, and is wholly utilised there in assisting the flow. This unchecked flow from one turbine to another is a great advantage of the parallel flow type over other types where a number of turbines are compounded. It also minimises the skin friction, as nearly the whole of the moving part is covered with blades, and there is consequently no appreciable loss due to this cause. As each turbine of the set gives 72·5 per cent. efficiency, it follows that as the steam at all points expands gradually without shock, that the motor as a whole will give an efficiency of at least 72 per cent. of the total mechanical energy of the steam, or, in other words, over 72 per cent. of the power derived from using the steam in a perfect engine, without losses due to condensation, clearances, or friction, and such like. A perfect engine working with 90lb. boiler pressure, and exhausting into the atmosphere, would consume 20·5lb. of steam per hour for each horse power; a motor giving 70 per cent. efficiency would therefore require 29·29lb. of steam per horse power per hour. We have now gone sufficiently into the question to show clearly that in the compound steam turbine we have a motor whose theoretical efficiency is very high indeed. The fact that at each turbine of the set the temperature is constant, enables us to predict that there can only be a very minute loss arising from condensation. This has been conclusively verified by experiments with superheated steam, coupled also with the fact that "for small differences of pressure gases and vapours act like liquids in flowing through orifices and tubes, in virtue of the small differences of pressure, and that the velocity of flow is regulated by the fundamental formula $v=8\sqrt{h}$." These three facts draw the analogy between the water turbine and the compound steam turbine for efficient working as close as it is possible to draw anything, and it does not seem too much to expect, in the larger sizes at any rate, an equally good efficiency.

The dynamo which forms the other portion of the electric generator, Fig. 1, is coupled to the motor spindle by a square tube coupling fitted on to the square spindle ends. The armature is of the drum type, the body is built up of thin iron discs threaded on to the spindle and insulated from each other by tracing paper. This iron body is turned up, and grooves milled out to receive the conducting wires. For pressures of 60 to 80 volts, there are fifteen convolutions of wire, or thirty grooves. The wire starting at *b*, Fig. 4, is led a quarter of a turn spirally *c* round the cylindrical portion *a*, then passing along a groove longitudinally is again led a quarter turn spirally *d* round the cylindrical portion *a*, then through the end washer and back similarly a quarter turn *e*, then led along the diametrically opposite groove, and lastly, a little over a quarter turn *f*, back to *g*, where it is coupled to the next convolution. The commutator is formed of rings of sections; each section is formed of short lengths; each length is dovetailed and interlocked between conical steel rings; the whole is insulated with asbestos, and when screwed up by the end nut forms with the steel bush a compact whole. There are fifteen sections in the commutator, and each coupling is connected to a section. The whole armature is bound externally from end to end with brass or pianoforte steel wire. The magnets are of soft cast iron and of the horseshoe type; they are shunt wound only. On the top of the magnet yoke is the electrical control governor, Fig. 3. It consists of one moving spindle, on which are keyed a small soft iron bar, and also a double finger T. There is also a spiral spring X attached at one end to the spindle, and at the other to an adjustable top head and clamping nut Y. The double finger T covers or opens a small hole in the face U, communicating by the pipe W with the diaphragm L. The action of the magnet yoke is to attract the needle towards the poles of the magnet, while by turning the head the spiral spring X is brought into tension to resist and balance this force, and can be set and adjusted to any degree of tension. The double finger T turns with the needle, and by more or less covering the small air inlet hole U, it regulates the access of air to the regulating diaphragm L. The second finger is for safety in case the brushes get thrown off, or the magnet circuit be broken, in which case the machine would otherwise gain a considerable increase of speed before the diaphragm would act. In these cases, however, the needle ceases to be attracted, falls back, and the safety finger closes the air inlet hole. There is no resistance to the free movement of this regulator. A fraction of a volt increase or decrease of potential produces a considerable movement of the finger, sufficient to govern the steam pressure, and in ordinary work it is found possible to maintain the potential within one volt of the standard at all loads within the capacity of the machine, excepting only a slight momentary variation when a large portion of the load is switched on or off.

The resistance of the armature from brush to brush is only ·0032 ohm, the resistance of the field magnets is 17·7 ohms, while the normal output of the dynamo is 200 ampères at 80 volts. This, excluding other losses, gives an efficiency of 97 per cent. The other losses are due to eddy currents throughout the armature, magnetic retardation, and bearing friction. They have been carefully measured. By separately exciting the field magnets from another dynamo, and observing the increased steam pressure required to maintain the speed constant, the corresponding power was afterwards calculated in watts. The commercial efficiency of this dynamo, after allowing for all losses, is a little over 90 per cent. In the larger sizes it rises to 94 per cent. Assuming the compound steam turbine to give a return of 70 per cent. of the total mechanical energy of the steam, and the dynamos to convert 90 per cent. of this into electrical output, gives a resulting efficiency of 63 per cent. As steam at 90lb. pressure above the atmosphere will, with a perfect non-condensing engine, give a horse power for every 20·5lb. of steam consumed per hour, it follows that an electrical generator of 63 per cent. efficiency will consume 32·5lb. of steam for every electrical horse power per hour. Again, with steam at 150lb. pressure above the atmosphere, a generator of the same efficiency would consume only 22·2lb. of steam per electrical horse power per hour.

The results we have so far actually obtained are a consumption of 52lb. per hour of steam for each electrical horse power with a steam pressure of 90lb. above the atmosphere. We, however, expect shortly to obtain results more nearly coinciding with those very high economies that theory has led us to believe possible with this system. In the larger sizes, so far as we have yet gone, we have invariably found increased economy, as in them the clearances are proportionately less, and it is easier to arrange the distribution of steam. Exceptionally low steam consumption is not the only essential attribute of an electric generator—there are other considerations, in most cases of more importance; these are steadiness of the current produced, freedom from accident, and simplicity, small first cost and cost of maintenance, little attention required, smallness of size and weight for a given output, and an almost insignificant consumption of oil.

To illustrate this, we will take the installation at the Phœnix Mills, Newcastle-on-Tyne, which has been running on the average of eleven hours daily for the last two years. Out of the original 159 Edison-Swan 16 c.p. lamps, sixty-five are still in good condition, having run 6500 hours at about standard brightness. Now, if the lamps had only lasted 1000 hours on the average, the cost of lamps renewed would have amounted to about double the year's cost of fuel as at present consumed.

At the Newcastle-on-Tyne Industrial Exhibition thirteen of these turbo-electric generators lighted the whole of the courts, giving a total of about 280 electrical h.p. During the whole run of the Exhibition the only noticeable accident which occurred to the installation was due to the blowing out of the packing in a branch steam pipe connecting another engine to the main steam pipe supplying the generators; but as there was no stop valve in this branch pipe the engineer in charge deemed it prudent to shut off steam at the boilers, thus stopping all the generators lighting the four courts for about three-quarters of an hour. This, however, was an accident quite external to the generator, and, as it happened, external to the main steam pipe supplying them. We believe that it was only on three occasions during the run of the Exhibition that a small group of lamps were extinguished for the few seconds necessary to enable a spare generator to be started and switched on to them. The seventeen generators were in two groups; had they been placed in one group the results showed that on all occasions one spare generator would have been sufficient to keep every lamp alight.

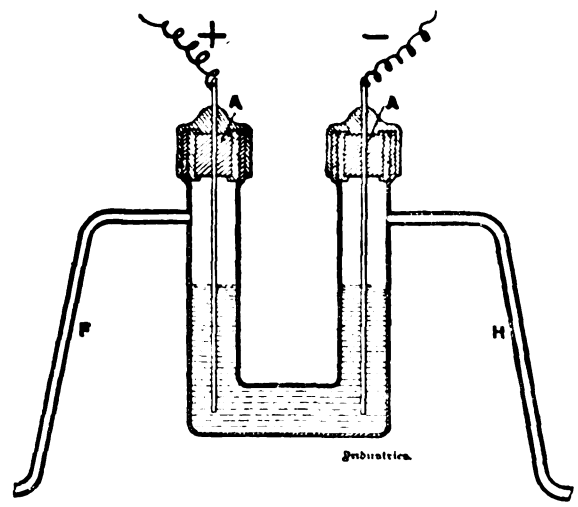
In regard to simplicity and cost of maintenance, we may say that in a 30 h.p. generator there is no part that three men cannot lift, and that every part is immediately accessible. After two years' working, of ten hours daily, we have found the wear very small indeed, in some cases almost inappreciable, the blades or vanes show no signs whatever of any cutting action of the steam. The commutators in the larger generators have generally withstood this amount of wear, while in some cases where they have been carefully attended they have suffered very little wear indeed. We have at the present time some important experiments being carried out in regard to the generators. It would, however, now be premature to foreshadow the probable results of these trials. We may, however, say that they lead us to conclude that, more especially in the larger sizes, a great increase in economy will be obtained, amounting to a reduction of from 20 to 25 per cent. of the steam consumption quoted in the paper. We may also add that we have now supplied generators giving a total output of 1280 electrical horse power—about two-thirds for ships, and one-third for land installation.

THE PHŒNIX FIRE OFFICE RULES FOR ELECTRIC LIGHT AND POWER INSTALLATIONS.—The eleventh edition of these rules has just been published, and contains some additions to the previous issues. Mr. Musgrave Heaphy, the able compiler of these rules, has on this, as on previous occasions, endeavoured to meet the just claims of electric light contractors, so far as this could be done without prejudice to the office which he represents, and to the many other fire offices which have adopted these rules. The additions chiefly refer to the introduction of alternating current systems, and we might specially mention one rule referring to the construction of transformers, in which Mr. Heaphy says that transformers should preferably be so made that a leak between the primary and secondary coils becomes impossible, or if this is not done an automatic arrangement should be added which will cut the current off if the difference of potential between the secondary circuit and the earth rises to 400 volts. Amongst the general rules referring to conductors, we would draw attention to No. 6, as this concerns a point which is often overlooked by electric light contractors. Under this rule conductors are not allowed to pass through party walls separating two risks unless with special permission from the Fire Office, and in that case provision must be made so that the conductors cannot become a means of communicating fire from one risk to the other.

CHEMICAL PROGRESS IN 1887.

A SUMMARY of the progress made in the chemical manufactures during the past year should include a consideration of those new discoveries in chemistry which may in the future be made the basis of manufacturing processes. It is not, however, an easy matter to select from the many new discoveries published from time to time in scientific journals, those which are certain to have industrial applications, since many processes which work well on a small scale are found to yield unsatisfactory results when tried on a larger basis. The distribution and economic erection of plant and the utilisation of waste products are matters which it is often difficult to regulate in a manner capable of rendering the process a remunerative one, even when the chemistry of the change has been clearly demonstrated in the laboratory. In the limited space at our disposal it is impossible to refer to the progress made in all of the various branches of the chemical industries. We cannot do more in the present article than briefly indicate the direction in which improvements are being made. The augmentation in production in nearly all the branches of chemical manufacture which was noticed in the year 1886 has been maintained, and in most cases a further development of trade has taken place. Increase in the supply has, however, been accompanied by a fall in prices in many chemicals, but the recent reaction in the metal market has to a considerable extent cancelled this diminution in price. The manufacturers of several articles in this country, and more especially in Germany, have by means of conventions succeeded in many cases in causing a marked improvement in prices, and considerable profits have been made in new articles for sanitary, pharmaceutical, and photographic purposes. The statistics for the current year are not yet completed, but we do not anticipate an unfavourable return. During the first six months of the present year our imports of chemicals, dyestuffs, and tanning substances show a slight falling off, while the exports for the same period were nearly the same in value as those of the corresponding period of last year. New drugs and Peruvian bark also showed a slight decrease, but the increase in price of quinine during the last few months, and recent improvement in the prices of pharmaceutical preparations, will probably alter this decrease. The Blue Book which was issued in October on our trade with the Colonies and foreign countries has shown that there was a diminution upon the figures of the previous four years both in imports and exports, with the exception of our export of chemical products and preparations, which showed a considerable improvement; and we expect that the returns for this year will show that this increase has extended to several other branches of chemical industry. Several important modifications in the different processes connected with the alkali trade in this country and abroad have been carried out during the past year. The yield of alkali by the Leblanc process has still further diminished, while there is a slight increase in the amount produced by the various ammonia-soda processes. In Germany the consumption of sodium carbonate has been gradually increasing, the increase being supplied by alkali produced by the newer process where 75 per cent., as compared with 22 per cent. in this country, of the total alkali is made on the ammonia-soda method. Germany is now competing with us in exporting alkali, but it is doubtful whether this competition will be a lasting one, owing to the geographical position of Great Britain and the cheapness of the raw materials in this country. The low price of alkali has caused the discontinuation of certain processes using hydrochloric acid, and several methods have been devised for replacing the Schaffner or Mond sulphur recovery process by one in which hydrochloric acid is not employed. Miller and Opl's method of converting vat waste into calcium sulphhydrate, and subsequently decomposing this by steam into sulphuretted hydrogen and lime, is now being tried abroad, and, if successful, the Leblanc soda process may have a little longer prolongation of its life. The production of a crystallised sulphide $Na_2S(6H_2O)$ by Schaffner and Helbig's process, Pechiney's method for the manufacture of sodium chlorate (and derivatives), and Mond's methods for obtaining ammonia, hydrochloric acid, and chlorine by means of nickel oxide, must not be omitted. Among the researches, which have been in progress for some time, with a view of obtaining chlorine and bleaching powder from calcium chloride residues, should be mentioned Solvay's process for decomposing it with silica at a high temperature, and Lake's recent American patents in the same direction, in which bricks are made from clay or silica and calcium chloride waste, which are subsequently decomposed at a high temperature by gases containing steam; caustic soda and the carbonates of the alkaline metals can also be made in the same manner if salt be added in the preparation of the bricks. With finely divided silica and salt, a mass suitable for the manufacture of glass, or, by melting with more soda, a soluble glass, is produced. Several substitutes for bleaching

Digitized by Google



powder have been introduced, and in Hermite's method for the preparation of bleaching solutions by electrolysis, we have a fresh competitor in this field of industry. Brin has recently patented a bleaching liquid, which consists of an aqueous solution of hydrochloric acid saturated with oxygen under pressure. With oxygen prepared by his new continuous process from baryta, this bleaching liquid can be produced at a price which should affect the price of the commoner bleaching substances. It requires no acid, and may be used in a similar manner to hydrogen peroxide. Several bleaching solutions containing chlorine compounds of aluminium have also been introduced during the last year. In the Stassfurt salt industry the production of carnallite has increased during the present year, and the output in other potassium salts, *e.g.* kainite, is also good; the extended use of these salts as artificial manures in this country and America having given an impulse to this branch of industry. Fischer has also described a method for working up Stassfurt potash salt liquors containing large amounts of common salt, such as those obtained in the manufacture of saltpetre, by which the potassium chloride is recovered, partly in the form of artificial carnallite, and partly as pure crystals free from sulphate. The extended use of Thomas slag as a commercial fertiliser has caused considerable depression in the artificial manure and superphosphate industries. Thomas slag appears to be of great value on sandy, peaty, and loamy soils, and from results obtained by its use, considerable economy is effected. The marked increase in the output of basic steel in England during the past year from 146,000 tons in 1886 shows that the supply of slag for fertilising purposes is not likely to be less than the demand, and we may expect that manufacturers will be able to sell at still more reduced rates. The slag has during the last year been used for the preparation of a hydraulic mortar with considerable success.

In metallurgy, especially in the electro separation of metals from the ores, and the application of chlorine and bromine to the disintegration of metallic compounds, considerable progress has been made, and among purely chemical processes, Castner's method for the preparation of the alkaline metals deserves mention. Metallic sodium can now be prepared at a much cheaper rate, rendering it available in many directions, and will considerably reduce the price of aluminium, and render it of more general application in the arts. Parkes' new process for smelting refractory ores with special fluxes and subsequent disintegration by water instead of by a mechanical operation, is stated to give a better yield than any of the older methods for recovering gold and silver from their ores. In mineral colours we may notice the depression in the manufacture of ultramarine, the extended use of zinc white (oxysulphide of zinc), and the mixture of zinc oxide and lead sulphate, known as non-poisonous white lead, as substitutes for white lead and chromate of lead (vermillionette) in the place of vermillion. Several improvements in the manufacture of white lead have to be recorded in this country and in Germany. Condy's method for preparing white lead rapidly by precipitation, and Löwe's German patent for obtaining the same by the addition of a solution of basic acetate of lead to precipitated lead carbonate, enable the manufacturer to turn over his capital more frequently than by the older Dutch process. Lyte prepares a basic lead acetate by pouring a solution of the neutral acetate over finely divided lead, which converts the normal insoluble lead salts (carbonate, sulphate, &c.) into white basic salts which are being used as substitutes for white lead. Before passing to a consideration of the progress made in organic chemistry we may draw attention to the extended use of boric acid as a preservative, and the increase of the amount of this acid exported from Italy during the last year. The alkaline fluosilicates have been recommended for the same purpose under the name of salufer, and antimony fluoride has been introduced as a mordant in the place of tartar emetic and antimony oxalate in dyeing. The coal tar colour trade deserves foremost mention among the chemical industries in organic materials, and here we notice the introduction of several new and valuable dyestuffs. The depression in this industry in 1885 was followed by a considerable rise in 1886; although reduction in prices took place to a slight extent, it was then balanced by the increase in the amount sold. Here, as in some of the branches of industry already alluded to, Germany has taken the lead, and her export trade has increased considerably during the last two years. Several new colouring matters belonging to the group of secondary azo dyes have been introduced into the market, which have the valuable property of dyeing cotton without the use of a mordant. Another dyestuff, having the same property, which dyes cotton blue, both in acid and alkaline solution, was introduced abroad at the end of 1886, is obtained from the diazo-derivative of diamido-diphenetol and α-naphthol sulphonic acid. Some new naphthol and naphthylamine monosulphonate derivatives may also be noticed. Roshydrazine, obtained by the reduction of diazotised rosaniline, is the base of a new class of colouring matters, consisting of condensation products with aldehydes and ketones, which can be formed on the fibre. A new method for the preparation of the azines has been described by O. Witt, which may in the near future have several industrial applications. Carbon sulphochloride $CSCl_2$ is being used as a new reagent for preparing thiobenzoic acid and thiophenone and derivatives therefrom. A violet dye can be prepared by the direct action of this body upon dimethylaniline in the presence of dry zinc choride. Colouring compounds, termed thiamines, obtained by the action of sulphurous acid upon aromatic amines, have been patented, and nitrated products, capable of dyeing and printing various shades of brown, have been obtained from them. Fahlberg's saccharine as a substitute for sugar may now be considered from a commercial point of view, the difficulties experienced in the oxidation and preparation of orthotoluene sulphamide having been overcome by the discoverer. Extensive works have been erected in Germany for the manufacture of this article, and when a cheaper oxidising agent than potassium permanganate is employed, or a convenient recovery process adopted, a less prohibitive price for this new sugar substitute may be expected. We have already briefly alluded to pharmaceutical preparations, but we must draw attention to the demand for several of the new alkaloids, *e.g.*, cocaine, berberine, veratrine, and caffeine, the latter being used as a substitute for digitalis. Among febrifuges and quinine substitutes, acet-anilide or antipyrine is in great demand. It is now prepared on a somewhat large scale from ethyl aceto-acetate and phenylhydrazine, and subsequently methylating the condensation product. Aconitine nitrate, camphor monobromide, hydrastine, hyoscyamine, and ditaine are also preparations for which there appears to be an increasing demand. The use of lanolin as a base in pomades and soaps, and first introduced by Liebreich as a result of his investigation of the wool of sheep, and separation of cholesterin therefrom, may be cited as another contribution of recent chemical research to our smaller industries.

In the domain of pure organic chemistry of great theoretical interest, is the preparation of the base hydrazine N_2H_4, the synthesis of glucose recently alluded to in this journal, and Horbaczewski's researches on the synthetical production of uric acid. We must draw attention, in conclusion, to the recent isolation of the element fluorine, in France, by the electrolysis of anhydrous hydrofluoric acid. The gas liberated has most powerful chemical properties, and agrees in character with the other halogens, thus fully confirming the theoretical conclusions which had been arrived at as to its nature.

THE ISOLATION OF FLUORINE.

The element fluorine has at last been successfully isolated, and its chief chemical and physical properties determined. Many chemists, notably Faraday, Gore, Pflaunder, and Brauner, have endeavoured to prepare this element in the free state; but all attempts have hitherto proved futile. M. Moissau, after a long series of researches

with the fluorides of phosphorus, and the highly poisonous arsenic trifluoride, has finally been able to liberate fluorine in the gaseous state from anhydrous hydrofluoric acid by electrolysis. This acid in the pure state is not an electrolyte; but when potassium fluoride is dissolved in it, a current from ninety Bunsen elements decomposes it, evolving hydrogen from the negative and fluorine from the positive electrode. The apparatus employed in this process is constructed of platinum, and is made in the form of a U tube, as shown in the accompanying illustration, with fluor spar stoppers, through which the battery terminals, made of platinum iridium alloy, are led. The gas is liberated at about the rate of two litres per hour, and has very powerful chemical properties. It smells somewhat like hypochlorous acid, etches dry glass, and decomposes water, liberating ozone, and forming hydrofluoric acid. The non-metallic elements, with the exception of chlorine, oxygen, nitrogen, and carbon, combine directly with it, evolving in most cases both light and heat. It combines with hydrogen, even in the dark, without the addition of any external energy, and converts most metals into their fluorides. Gold and platinum are not attacked in the cold, but when gently heated are easily corroded. Mercury readily dissolves the gas forming the protochloride, iron wire also completely absorbs the gas, while powdered antimony and lead take fire in it. It is necessary in the electrolysis of the liquid hydrofluoric acid to cool the electrolytic cell by means of methyl-chloride to −50° C. Fluorine appears to thus fully confirm the predictions which have been made by chemists concerning its properties. It is by far the most energetic of all the known elements, and its position in the halogen series is established by its property of not liberating iodine from the iodides of potassium, mercury, and lead, and also of setting free chlorine from potassium chloride. With iodine it appears to form a fluoride. No compound with oxygen has yet been obtained.

THE SOCIETY OF CHEMICAL INDUSTRY.

On January 2nd, at a meeting of the Society of Chemical Industry, held at Burlington House, Mr. A. Gordon Salamon read a paper written by himself and Dr. J. J. Hood, entitled "A New Method of Removing Sulphur Compounds from Coal Gas." The authors stated that the purification of coal gas may be regarded from two points of view, viz., as a necessity and a difficulty, and that the latter is the bugbear of the gas companies, eased somewhat by the fact that the removal of all the impurities is not insisted upon by the Government, because the task is impossible. The impurities to be reduced are carbonic acid, sulphuretted hydrogen, carbon bisulphide, and some complex sulphur compounds. The carbonic acid is removed by means of calcic hydrate; oxide of iron, in the form of a bog iron ore obtained from the North of Ireland, is spread upon grids, and used to eliminate sulphuretted hydrogen. Between each exposure to the gas it is submitted to the action of common air, and after twelve successive exposures to the gas, it refuses to take up more sulphuretted hydrogen. This process, however, is expensive, the ore costing 30s. per ton delivered in London. Two tons of the ore are required to take up one ton of sulphur, and the sulphur afterwards obtained from it is free from arsenic. The used ore is then thrown away as absolute refuse. There is a loss of about 14s. on every ton of sulphur produced, exclusive of the cost of labour, which brings the loss to the gas companies up to 26s. The other sulphur compounds are more difficult to extract, and the present method is unsatisfactory. The weak affinity of carbon bisulphide for sulphide of lime is utilised, and the resulting waste product is the "blue billy" of gas companies: it is a nuisance to the managers and to the neighbourhood, although some few persons profess to thrive upon its evil odours. The new plan of the authors, they stated, involves no alteration in the existing plant of gas companies, and the substance utilised can be employed in the dry state. Its trials have mostly been upon a laboratory scale, and although it has also been tried with some tons of material, the experiments on a large scale are not yet finished. The reason that the matter has been somewhat early brought under the notice of the Society is, that the authors did not select the date at which their paper was to be read. So far, they were very well satisfied with the results on a large scale, but would not publish them until the series were complete. The substance they use is the "Weldon mud," from which the calcic chloride is removed by washing. After three decantations but two or three per cent. of the chloride is left. The mud is then dried, and forms a porous mass which crumbles between the fingers; it keeps well, being found not to appreciably lose its useful properties by exposure to the air; it consists of a mixture of hydrated oxides of lime and manganese. The following is the

Composition of the Prepared Weldon Mud "A."

MnO_2	28
MnO	9
CaO	11
$CaCl_2$	3
H_2O	46
Insoluble	3
	100

The $CaCl_2$, so largely removed, is liable to form a glaze over the mud, and to reduce its efficiency. When it contains no more than 3 per cent., the mud is suitable for the purpose. It absorbs carbon bisulphide, and then when exposed to the air does not give off a foul smell,

Digitized by Google

so is likely to do away with the nuisance of "blue billy." The authors then exhibited a vertical tube about 8in. long by 2in. diam., plugged at the top and bottom with cotton wool, and filled with the prepared Weldon mud, through which they passed a stream of sulphuretted hydrogen all the rest of the evening; the tube gradually grew very hot, and the mud turned yellow as the absorption went on; from time to time during the evening, the chairman (Mr. D. Howard) testified that no smell escaped from the upper part of the tube. They had not found that the compound formed had any tendency to fire in the gas purifiers, and so neutralise the value of the process. They had proved that the oxide of calcium present was not the active agent in producing the results, and with seven revivifications they had charged Weldon mud with sulphur to the extent of 70 or 80 per cent. In making comparisons, it must be remembered that Weldon mud during the action grows greatly in weight, whilst bog iron ore loses a little in weight.

Comparison of Bog Ore with Weldon Mud sulphurised five times, and purified for one hour each time.

100 Bog ore (34 per cent. Fe_2O_3) took up 27 S.
100 Weldon mud (28 per cent. MnO_2) took up 61 S.

Sulphurisation of Weldon Mud "A."

Sulphurised and Revivified.	Sulphur per 100 of mud. By CS_2.	By acid.
1	19	25
2	37	43
3	42	53
4	45	58
5	57	66
6	60	70

With twelve revivifications it is not possible to get more than 50 per cent. of sulphur upon bog iron ore. The new process gets rid at present of 25 per cent. more than does the bog ore process of the complex sulphur compounds in coal gas, and the Weldon mud can be revivified by blowing air through the purifiers, without removing it therefrom. There are no by-products to give off evil smelling gases, and the residue can be restored to the condition of active Weldon mud after the sulphur is removed. Its value to the bleach maker is reduced by one-half; but the lime is separated by sulphuric acid, so he does not have to use hydrochloric acid. Bleach makers do not look on the presence of sulphate of lime with favour; however, in the present case they gain a sulphur precipitate worth £7 per ton, and can then return the mud to the gas maker, so that the whole cost is for the hire of the Weldon mud.

In the discussion, Mr. Mead argued that the present process with bog ore was a cheap one. Mr. Campbell contended that there must be an objectionable quantity of sulphate of lime in the used Weldon mud, as indicated by the figures given, and nothing had been said about the cost of the Weldon mud, which he expected must be at least three times that of bog ore, cost of carriage of the former excluded. Mr. Salamon would not go into the entire question of cost until the experiments upon a large scale were completed; but so far the inventors were exceedingly well satisfied with the results, and thought that even if the new compound did no more than to get rid of "blue billy," its use would be of enormous advantage.

Notes.

FLOUR MILLS IN ITALY.

There are in the province of Ancona, says Vice-Consul Tomassini, 205 flour mills worked by hydraulic, and three by steam power. These employ 376 adults and eleven boys under fourteen years of age. A mill at Camerala Picena, known as the "American Mill," is worked by a turbine of 120 h.p., an 80 h.p. steam engine being kept in reserve. The total estimated value of the production of these mills is £400,000 for wheaten flour, £160,000 for Indian corn flour, and £100,000 for flour from other inferior cereals.

ALUMINIUM.

We are likely before long to have a deluge of aluminium alloys. Two large works are at the present time being erected in this country for the production of these alloys—the one by Cowle's Company, and the other by the Aluminium Company, Limited. The former company use an electric furnace; the latter, Castner's modification of the Deville process. There is a question as to which process gives the best and the most economical results. The Cowle's Company have not yet produced, or at any rate they have not offered for sale, pure aluminium, while the Aluminium Company have produced and sold the aluminium in its pure state. There is probably but little demand for the pure metal, as such; but it is none the less clear that if pure aluminium is offered the range of its use may be indefinitely extended, whereas the production of alloys alone limits such range. It appears to be likely that before long aluminium alloys will largely take the place of iron and steel, and probably also of Delta and Muntz's metal, for purposes in respect of which great tensile strength and non-liability to corrosion are elements of importance.

HEATING RAILWAY CARRIAGES BY STEAM.

The number of fatalities caused in the United States by the use of the old car stove has rendered it imperative that some new method of heating should be devised, and the law passed by the Legislature of the State of New York in the same direction has resulted in experiments in steam heating being made by almost all the prominent railroads. The methods used are nearly the same on all lines, steam being taken at a low pressure, and distributed by means of pipes throughout the train. On the New York Central line a fixed 2in. pipe runs under each car, connection being made between the cars by a section of pipe moving freely with a ball and socket joint. Inside each car there are two pipes running the length of the car, with branches under each seat. The pipes inside the cars can be cut off from the main steam pipe underneath, allowing the temperature of each car to be regulated independently.

AN ELECTRIC CHESS RECORDER.

We had last week an opportunity of inspecting, at the offices of Messrs. Woodhouse & Rawson, of Queen Victoria-street, London, a new apparatus, devised by Dr. Wurstenberger, of Zürich, for automatically recording a game of chess as it is being played. The record is printed on a tape in the usual way, that is to say, by reference figures and numbers. As customary, the position on the board is defined by two co-ordinates, one referring to the distance from the left hand corner to the right, and the other to the distance across the board, the former being given by a letter, and the latter by a number In printing the record, the number is printed immediately below the corresponding letter for the white pieces, and with an intervening space below the letter for the black pieces. The pieces are provided with plugs which fit corresponding holes in the board, the plugs of the white pieces being of wood, and those of the black pieces of metal. The record is transmitted from the board to the printing apparatus by means of electricity, there being sixty-four separate wires joined into a cable. Each black piece, when being taken up or put down, completes by its metal plug a circuit which actuates an electromagnet. The armature of this magnet is then attracted, and displaces the spindle of the type wheel carrying the numbers longitudinally, and thus provides the wider spacing between the letters and numbers for the black moves. When the white pieces are inserted or withdrawn, no current is sent into this magnet, and the type wheel carrying the numbers remains close to and side by side with that carrying the letters. The plugs at the bottom of the chessmen have, however, also another function to perform. In being withdrawn or pushed in they deflect contact springs, and by this means a current is sent along that particular wire which corresponds to the square on the board from which a piece is taken up or on which a piece is set down. These wires terminate at the printing apparatus in forty-six segments arranged in two discs, thirty-two in each, and round each disc revolves a small brush, the motive power being derived from a spring, very much in the fashion of an ordinary Morse receiver, and the paper strip is at the same time advanced. As soon as the revolving brush comes opposite the segment connected to the wire corresponding to the position on the board which is to be recorded, the circuit through this wire and through another electromagnet is completed, by this means raising a roller and pressing the tape against the type wheels, as in all printing instruments. From our description it will be seen that the pieces must be taken up and set down slowly, so as to give the brush time to revolve until it meets the particular segment from which the current is sent to the electromagnet; but the inventor, in order to obviate this difficulty, has introduced a relay between the board and the printing instrument, so that the pieces may be taken up or set down as fast as may be desired. On our visit, however, we did not see this relay in action, it having been damaged during transit. Dr. Wurstenberger's chess recorder is a very ingenious piece of delicate electrical machinery, but it has evidently only a limited field of application. It would principally be useful in clubs, where it may be desired to record in one room the game being played in another; but as there are sixty-four circuits, it could not be employed for telegraphing the game to any distance.

THE PROMOTION OF TRADE WITH PERSIA.

An exhibition of Russian manufactures suited to Persian requirements is to be held this year at Tehran, and in referring to it the British Consul-General at Tabruz states that it is to be hoped such a display of Russian activity in commercial centres of the far East will serve to awaken our merchants and Chambers of Commerce to the necessity of quickening the pace of British enterprise in Oriental markets. A step in the right direction would be to send from time to time competent persons to study the principal markets of Central Asia and Persia. He remarks: "The imports into Persia from British India amount annually to considerably over a million sterling. The question suggests itself whether an exhibition at Ispahan or Tehran—whichever be most expedient—of British and British-Indian manufactures suited to Persian requirements, could not be also opened? Such an exhibition would doubtless stimulate the trade between Her Majesty's Indian possessions and the southern dominions of the Shah—England and Persia sharing mutual benefits."

PUBLIC WORKS IN ITALY.

The British Consul at Venice reports that the Italian Parliament has at last sanctioned the expenditure of £180,000 for the prolongation of the north-east breakwater of the port of Lido for a further distance to the sea of 500m., and for the construction of the south-west breakwater to a length of 2850m. The large dry dock is also to be lengthened at a cost of £10,000, in order to allow of ships of any size being docked in it. The opening of the port of Lido will greatly increase the importance of the arsenal of Venice. A contract has been made by the Berliner Maschinenbau Actien-Gesellschaft (L. Schwartzkopf) with the Ministry of Marine for the construction of a torpedo manufactory in Venice, which is already in progress. The Italian Government will take over the torpedoes to be made there, and the municipality is to construct a large basin near the port of Treporti, for the use of the Berlin firm, at the expense of the town.

MAGNIFICENT PRODUCTION OF TEXTILE ART.

In Ireland, as in all other parts of the world, subscriptions have for many months back been collected for the purchase of presents for the Pope on the celebration of his Jubilee. Of these none can lay any claim to the magnificence and grandeur embodied in the textile offering of the Passionist Fathers of the Holy Cross and Ligoniel Congregations, Belfast. The gift consisted of a table cloth and two napkins of a design and finish to which no description could well do full justice, and it may safely be said that no production of similar textile work has ever been able to excel, if ever equal it, in point of beauty, quality, and magnificence of detail. One feature of the presentation is, that it is the work entirely of Irish operatives, having been prepared and woven in the celebrated damask factory of Mr. Michael Andrews, Ardoyne. The articles are hand woven, the warp being of linen threads and the weft of the finest silk. The table cloth is $2\frac{1}{2}$ yards by 3 yards, while the design and style of the napkins are made to match. These latter are the sole property of the manufacturer, and are alone sufficient to testify to the high degree of excellence which the factory at Ardoyne has attained. The design may be described as an Italian scroll, with a frieze work, and an inner border of similar arrangement. The centre is decorated with the arms of the Pecci family, which is surmounted by a representation of the cross keys and tiara—the papal insignia. Over these again is shown a scroll with the words "Lumen in Cœlo," while immediately underneath appears the year of the birth of Leo XIII., "1810." Further down the design, below the Papal arms, another scroll is placed on which is inscribed "1837—Jubilee—1887." Towards the edges of both cloth and napkins the inscription, "Presented by the Holy Cross and Ligoniel Congregations, Belfast," appears, while the title of the manufactory, and the initials of Mr. Andrews, "M.A.," are worked delicately and beautifully in. The pendants of the fabrics are representations of the badge of the Passionist Order, and figures of the Irish harp enclosed in a wreath of the national emblem—the shamrock—form the side pieces. The warp threads used in the manufacture of this gift are probably the finest which have ever been produced in Belfast; the beam consisting of no fewer than 12,000 threads for the table cloth, and rather under 4000 for each napkin. The weft is of China warp silk of the most perfect quality, or, as technically termed, China organzine, and of which 250 to 260 shots per inch were thrown. This therefore makes it, so far as is known, the finest wefted cloth in existence. By the blending of the linen warp and silk weft in such a manner, the production has the appearance of a cloth of gold. The entire work is indeed so perfect, and was shown with such good effect on the purple draped walls of one of the reception rooms of the monastery at Holy Cross, that it was difficult to conceive it to be the production of mechanical ingenuity. With this presentation Leo XIII. possesses a specimen of one of the world's marvels in textile manufacture, and no doubt it will prove one of the chief attractions in the exhibition of his Jubilee presentations.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

30th December, 1887.

17910. Brook, E. ..... Looms.
17912. Prunier, E. ..... Force pumps.
17915. Fairweather, W..... Propelling ships.
17916. Longsdon, H. C..... Machines for smoothing textile materials.
17918. Richards, G..... Shaping machines.
17923. Smith, J. W..... Locomotive engines.
17939. Hawkins, R. B..... Rotary brushing machines.
17944. Speed, J. J. ..... Magazine fire arms.
17948. Gruhl, A..... Button machinery.
17954. Worth, J. S..... Cranes and hoists.
17955. Lee & Burnham ..... Knitting machines.
17959. Lee, E. W..... Knitting machines.

31st December, 1887.

17974. Thompson, W. P..... Type writers (*The Standard Type Writer Manufacturing Co.*).
17977. Robertson & Orchar. Machines for finishing woven fabrics.
17978. Corrigan, J. ..... Reeling machines.
17990. Hogg, T. C. ..... Hydrocarbon engines.
17995. Eadie, R., & others..... Ring doubling machines.
18006. Fantzen & Lutz..... Cocoa grinding apparatus.
18008. Ainsworth, J. T..... Mules.
18009. Gleed, A. W. ..... Machinery for grinding and crushing.
18014. Crampton, H. ..... Guns.
18016. Chwalla, G..... Manufacture of fancy pile fabrics.
18018. Burckhardt & Weiss... Surface condensers.
18019. McHugh & Ward..... Machines for embossing plastic materials.
18023. Hipkins, B. E. ..... Steam boilers.
18025. Adant, G ..... Apparatus for grinding sugar.
18029. McKean, J. A. ..... Apparatus for tunnelling rock.

2nd January, 1888.

11. Porteous, A. N. ..... Counterthrust engines.
12. Spittle & Sanders..... Improvements in engines.
16. Willcox, B. ..... Coupling for propeller shafts (*La Société des Usines Franco-Russes*).
17. Eckardt, E. M. ..... Pistons.
18. Craven, W. ..... Bearings for travelling cranes.
19. Pielsticker, C. M. ..... Compound steel plates (*Williamson*).
26. Willcox, B. ..... Machinery for lasting boots and shoes (*Chase*).
31. Grollimund, M. ..... Grain cleaning and separating mills.
33. Stuart, H. A. ..... Sewing machines
36. Gubbins, R. R..... Manufacture of bar iron.
45. Norris, W. ..... Button hole sewing machines.
51. Willans, P. W. ..... Pistons.
52. Jefferies & King ..... Thrashing machines.
53. Lea, J. P. ..... Steam engines.
54. Chouliac, A. L. A. ..... Rotary engines.

3rd January, 1888.

57. Allison, H. J. ..... Button hole attachments for sewing machines (*Pippey*).
62. Welshman, W. H. ..... Apparatus for shaping press tools.
67. Richardson, W. E..... Weighing machine.
70. Semple, H. ..... Bottle finishing machines.
72. Thompson, W. P..... Type writers (*Brown*).
91. Moore, F..... Machines for drying wool.
109. Abel, C. D..... Regenerative gas furnaces (*Glaser*).

4th January, 1888.

117. Williamson, D..... Rotary engines.
123. Dorman, W. H..... Circular knitting machines.
128. Adamson, D..... Steam boilers.
132. Robins, J. J..... Excavator.
141. Brown, J. H..... Magazine fire arms.
146. Christie, R. C. & oth... Controlling the recoil of guns (*Canet.*)
150. Hunter & McCreadie.. Picking motion.
152. Simon, G..... Magazine rifle.
156. Thompson, W. P..... Superheating steam.
159. Thompson, W. P..... Ploughs (*Ventzki*).
165. Gibert, F..... Propelling apparatus.
174. Norton, J. A..... Machine guns.

5th January, 1888.

183. Saxby, J., & others ..... Interlocking apparatus for railway signal levers.
190. Hall, C. E. ..... Slide valves and reversing gear.
191. Bennett, J. M..... Smelting furnaces.
192. Berry, H. ..... Hydraulic cylinders.
213. Yaryan, H. T. ..... Evaporating and distilling apparatus.
220. Anderson & Longridge Armoured ordnance.
221. Bourdil, F. F. ..... Piston packings.
222. Mackenzie & Armstrong ..... Fret cutting machine.

ELECTRICITY.

30th December, 1887.

17926. Hayne, W. E..... Safety fuses for electrical circuits.
17935. Cardew & Brett..... Incandescent electric lamps.

31st December, 1887.

17966. Rhodes, O. Y. ..... Electric batteries.
18015. Bernheim, E. I. ..... Electrical connections.

2nd January, 1888.

20. Sherrin & Sherrin..... Propulsion of velocipedes by electromotors.
39. Tyer, E. ..... Voltaic batteries.
40. Tyer, E. ..... Electrical block indicators for railways.
41. Tyer, E. ..... Voltaic batteries.
56. Johnson, J. Y..... Incandescence electric lamps (*Mace*).

3rd January, 1888.

100. Lake, H. H..... Apparatus for generating electricity (*Humans*).

4th January, 1888.

112. Joel, H. F..... Incandescent lamp holders and switches.
115. Baynes, S. W..... Insulation of electric appliances.
137. Pürthner, J. C..... Producing electric streams.
155. Boult, A. J. ..... Electrical turnstiles (*Ehrling*).

5th January, 1888.

208. Ross, O. C. D. ..... Utilisation of waste products from electrical batteries.

CHEMISTRY.

30th December, 1887.

17908. D'Andria, M..... Separating arsenic from hydrochloric acid.
17909. D'Andria, M..... Treating acid residues from galvanising works.
17921. Finch, H. ..... A new reagent for bleaching.
17925. Groth, L. A..... Black liquid prepared from aniline (*Collin & Errani*).
17946. Walker, A. J. ..... Apparatus for oxidising yeast.

31st December, 1887.

17969. Hermite, E., & others.. The manufacturing of bleaching liquor.
17970. Parnell & Simpson ... Carbonate of ammonia and sulphuretted hydrogen.
17980. Pumphrey, A. ..... Photographic films.
18022. Briant & Clowes ..... Yeast.

2nd January, 1888.

43. Pfeiffer, J..... Manufacture of dry calcium hydroxide.

3rd January, 1888.

86. Dechend, F. von ..... Reduction of nitro compounds.

4th January, 1888.

119. Williams, R..... Manufacture of cyanides.
120. Goodman, G. H..... Preparation of carbonaceous fuel.
170. Abel, C. D..... Sulpho acids of diphenylamine (*Zimmer*).
173. Solvay, E..... Sodium bicarbonate.

5th January, 1888.

181. Kenyon, H..... Treating iron saturated with matters containing sulphur and nitrogen.

MISCELLANEOUS.

30th December, 1887.

17906. Pluck, J. ..... Improvement in corkscrews.
17917. Shanks & Burnside. .... Improvements in float cocks.
17919. Heys, D. S..... Balancing weights for windows.
17920. Moon, G. W. ..... The construction of wheels.
17922. Fisk, T. ..... An improved pipe connector.
17929. Carter & Carter ..... Apparatus for ventilating.
17931. Jackson, T. ..... Syphon tap.
17932. Stanton, F. B. ..... Railway buffers.
17933. Garner, R. ..... An improved gulley trap.
17934. Drummond, F. A..... Water gauge for steam boilers.
17936. Pottier, C. ..... Hot air stoves.
17937. Altmann, A..... Regenerative lamps.
17938. Cook & Ingham ..... Retorts.
17940. Allen, F. J. B..... Burners for lamps.
17941. Davis, M. ..... Lamps (*Eckel & Glinicke*).
17942. Allen, F. J. B..... Lamps.
17950. Wright & Mackie ..... Apparatus for working heated glass.
17952. Abel, C. D. ..... Azo dyestuffs (*Actiengesellschaft für Anilinfabrikation*).

31st December, 1887.

17961. Williams, M. C. ..... Horizontal beam compasses.
17962. Bagshaw, W. ..... Instrument for measuring the average pressures of diagrams.
17963. Purves, D. ..... Valves.
17967. Gregory, B..... Manufacture of blue bricks and fire bricks.
17968. Wilson, W. ..... Ventilator.
17972. Statham, S. E..... Vulcanisation of objects made of pure india-rubber.
17976. Vickery, A. ..... Saddle bars.
17985. Middleton, C..... Regulating the supply of gas.
17987. Bowie, MacN. C..... Gas lamps.
17991. Tuff, J. R. ..... Velocipedes.
17992. Howarth, G. ..... Callipers.
17993. Winterflood, J..... Ventilating cowls.
17996. Cooper, E. W. ..... Rotating chairs.
17997. Potter, C..... Carts and vehicles.
17998. Nicholls, P..... Manufacture of boots.
18000. Murrie, J. ..... Governors.
18004. Prandstätter, M..... Recording apparatus for carriages.
18007. Allan & Holmes..... Adjustment of sliding sockets upon their rods.
18012. Woodruff, O. D..... Meat cutters.
18013. Walter, F. ..... Bottling apparatus for aerated liquids.
18017. Lake, H. H. ..... Call bells (*Russell*).
18020. Thornton, J. ..... Pipe coupling.
18021. Nicholson & Allcock Horse rakes.

2nd January, 1888.

2. Archer, T. ..... Controlling the running out of ropes and chains.
3. Bradsworth, A. ..... Automatic signal for picking and finishing machines.
5. Eshelby, J. ..... Oil lamps.
6. Holden, G. H..... Stop motions for twisting and doubling frames.
7. Hanson, J. ..... Railway chair.
9. Plenty, E. P..... Forced draft closed ash pits.
10. Hargreaves & Carr ... Slide valve.
21. Evans, A. G..... Removing scale from steam generators (*Livock*).
22. Groombridge & Rickman..... Lock bolt.
25. Edelboum, I..... Ventilator.
28. Eli, A. J. ..... Lamps for burning petroleum.
29. Barnard, J. H..... Slow combustion stoves.
30. Bay, A. V..... Dampers for steam boilers.
35. Sewall, J. H. ..... Apparatus employed in heating railroad cars.
42. Tyer, E. ..... Apparatus for securing safety of traffic on single lines of railway.
47. Pont, A. de ..... Process of producing imitations of ivory.
48. Pont, A. de ..... Process of treating horn waste.
50. Morgan, D. J. ..... Improvements in ships' lights.

3rd January, 1888.

58. Dion, L. O. ..... Method of fastening strips of leather together.
60. Hall, W. P. ..... Railway ties.
61. Gregory & Gilfort ... Spring safety hooks for couplings
79. Fairweather, J. I..... Ball valve for cisterns.
85. Wilkes, J..... Tools used in mining and quarrying.
87. Thompson, W. P..... Method of producing dyes for use in making wood type (*Satchell & Page*).
94. Haddan, H. J..... Lock fastenings (*Kristoffy and others*).
98. Lake, H. H..... Rails, sleepers, &c. (*White*).
99. Lake, H. H..... Soil fertiliser distributors (*Peabody*).
103. Davids, C. H..... Apparatus for numbering or counting.
106. Lake, H. H..... Brakes for railways (*Schauffler and Bayon*).
107. Kapteyn, A. P..... Automatic brake.

4th January, 1888.

113. London & Stuart..... Sight feed lubricators.
116. Weston, T. R..... ... A mechanical trap.
118. Brooks, S..... Smoke consumer.
122. Carus-Wilson and Bayley..... Lock nut.
126. Cole & Cole..... Gas govenors.
134. Beal, W. H..... Driving appliances.
135. Hargreaves and Bardsley..... Gas regulators.
136. Weber, F. A..... Heating and ventilating.
139. Wardale, J. M..... Bow drill.
142. Brown, A. M..... Wheels and pulleys.
143. Chandor, L..... Lamps.
145. Radford, H. G..... Block fuel.
147. Flohr, O..... Friction clutches and hoists.
158. Thompson, W. P..... Regenerative gas lamps (*Schmidt and others*).
163. Edgley, M. W..... Water taps.
166. Thame, J. R..... Manufacture of paper boxes.
167. Wood, E. A. ..... Bow rudder.
168. Liddell, W. A..... Gabions.
169. Langen, C. J. ..... Apparatus for drying
171. Wild-Wirth & Wild... Production of chromo-lithographic surfaces.
172. Marth, R..... Collapsible boats.

5th January, 1888.

177. Healey & Thwaite..... Application of gaseous fuel for treating towns' refuse.
184. Lee, A. H..... Gearing for velocipedes.
185. Clifford, A..... Fire extinguisher.
186. Lewthwaite, S. ..... Gas heating apparatus.
188. Whitehouse, J. ..... Cutting tools.
189. Vereker & Yeates..... Starter of tram cars.
195. Collier, L. ..... Feeder for guiding mills.
201-2. Thompson, W. P..... Wood type (*Setchell*).
203. Gittus, H..... Belt fastener.
206. Bourdon & Morel ..... Warming railway carriages.
209. Nibbs, F. I. ..... Driving gear for velocipedes.
210. Spackman, H. ..... Lamps.
211. Morris, R ..... Filters.
212. Pasquet, P. G..... Lubricators.
216. Haddan, H. J. ..... Ball bearings (*Hellmann & Fichtl*).
217. Trott, H. ..... Regulating the flow of water in pipes.
218. Vaughan & Foster..... Hooks for cranes.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

7th January, 1888.

12521. Normanville, W. de ... Rotary engines.
17063. Nicholls, H. M. ..... Printing machines.

Digitized by Google

17129. Southall & Clegg..... Apparatus for sorting, cleaning, and travelling coal.
8. Turnock, J. R..... Steam engines.
19. Chappell & Chappell. Propelling ships and boats.
310. Lapage, R. H. ..... Compound engines.
447. Haddan, H. J. ..... Crushing apparatus (*Newerburg*).
910. McFarlane, L. ..... Paper making.
1358. Jackson & Martin..... Sewing machines.
1878. Stevens, S. ..... Metal folding machines.
2876. Justice, P. M. ..... Rolling mills (*Daniels*).
3049. Tranter, W. ..... Small arms.
3132. Rickaby, A. A. ..... Casting rings of metallic packing.
3224. Newton, H. E..... Condensing apparatus (*Theisen*).
3294. Alley & MacLellan ... Apparatus for making moulds for casting.
3297. Whalley & Wells..... Brake mechanism of looms.
3306. Greenhalgh, J., & others Opening and cleaning cotton.
3368. Flather, A. ..... Jacquard machines.
3635. McCulloch, A., & others Spinning machinery.
3871. Sykes, T. S. ..... Machine for cutting samples of fabrics.
4624. Newton, H. E..... Propulsion and steering of vessels (*Merlette*).
5472. Stinton, E. ..... Shaft bearings.
5981. Korting, E. ..... Gas motors.
7309. Leader, A. W..... Sewing machine.
11915. Boult, A. J. ..... Steam engines (*Case*).
13689. Firth & Shackleton ... Combing machines.
13705. Stewart, C. F..... Machine for making dowel pins.
13770. Hiron, H. F..... Anchors.
16331. Hennecke, W. H. A. ... Thrashing machines.
16404. Lake, W. R. ..... Propulsion of tramway vehicles (*Patton*).
16555. Lilienthal, O..... Tubular boiler.
16741. Allison, H. J. ..... Grain binders (*Milwaukee Harvester Co.*).
16781. Vaughan, G. E..... Machines for bagging chaff (*Andrews & Beaven*).
16782. Lake, W. R. ..... Boiler furnaces (*Dashiell*).

ELECTRICITY.

7th January, 1888.

1654. Kingsland, W..... Secondary battery cells.
2851. Parker, T. ..... Automatic switch for electrical circuits.
3197. Salomons, Sir D. L., and others..... Secondary batteries.
3469. McEvoy, C. A. ..... Electric primers for firing breech loading guns.
4478. Maynard, C..... Carrying telegraph wires.
11448. Sellon, J. S..... Secondary batteries.
16128. Munns, W. H. ..... Telephones (*Sunderland and Monjo*).
16669. Bailey & Warner ..... Secondary battery combined with a miner's lamp.
16728. Heintz, A..... Incandescent electric lamps.

CHEMISTRY.

7th January, 1888.

15942. Kellner, C. ..... Cellulose.
3144. Pattinson, H. L..... Hydrates of barium and strontium.
3389. Towlson & Weldon..... Aniline blacks.
3670. Lloyd & White ..... Manufacture of cast steel.
16592. Offen & More..... Yeast.

MISCELLANEOUS.

7th January, 1888.

17145. Laval, C. G. P. de ..... Cream separators.
185. Harrison, J. A. ..... Lubricating cans.
579. Thomas, T. C. J. ..... Lamps.
1551. Torkington, J., & others Economising gas.
1811. Thompson, W. P..... Warming and ventilating (*Smead*).
1818. Sneade, W. S. ..... Rollers for grinding pigments.
2601. Ramsay, H. ..... Guard for hoist wells.
2848. Kimberley, W. ..... Plough and sash fillister planes.
2867. Brooks, S. H., & others Self contained spindles.
3119. Atkins, W. ..... Spirit lamps.
3156. Capewell, G. J. ..... Nail extractors.
3183. Langfield & Martland Heating railway carriages.
3231. Sutton, J. W. ..... Knife cleaning machines.
3248. Béjot, A. J. ..... Apparatus for printing in colours.
3279. Prince & Symmons..... Hydrocarbon lamps.
3282. Brown & Pickstone ... Improvement in bobbins for winding yarns.
3344. Smith, R. W..... Bicycles and tricycles.
3350. Griffin, S..... Stuffing boxes.
3359. Davis & Turner..... Supply of gas to gas stove hot plates.
3362. Swan, J. W. ..... Detection of explosive gases in mines.
3374. Barlow & Barlow..... Mounting wire or metal healds.
3461. Bischof, G. ..... Apparatus for purifying water.
3568. Girling, G. G..... Manufacture of artificial stone.
3617. Craig, A. F., & others ... Separating mineral from substances of different specific gravities.
3657. Chantrell, W. S..... Lubricators.
3789. Hunt, H..... Fire grates.
3890. Taylor, J..... Ventilator.
3916. Williamson, T. ..... Saw sets.
4381. Auton, R. ..... Artificial fuel.
4485. Clark, A. M..... Process of ornamenting glass (*Brunetti*).
4818. Taylor, S..... Metal covered roofs.
5982. Enzinger, L. A. ..... Filter presses.
8696. Notley, W. ..... Safety lamp burner.
11707. Allison, H. J..... Wind gauge sight for fire arms (*Lyman*).
11987. Beale, W..... Tyre for road vehicles.
15869. Hayes, W. R..... Ventilators.
16361. Grassler & Elliot .... Automatic pipe coupling for heating railway cars.
16411. Henney, J. ..... Heating railway carriages.
16517. Furnival, T., & others.. Printing machines.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Preparing Wool for Spinning.—*J. W. Smith, Bradford, Yorkshire.*—In the improved machine for drawing and preparing wool and other fibres the inventor dispenses with the usual creels at the back for supporting the supply bobbins, and with the spindles and flyers used for twisting and winding the slivers delivered by the front rollers. The slivers to be reduced or drafted are placed in cans in a practically untwisted condition, and each can is placed on a plate revolving at such a speed as to give the necessary amount of twist to the sliver before it enters the nip of the back rollers. The slivers are drawn or reduced by the front rollers, and are deposited in revolving cans in the front of the machine. Claim: The described process of reducing slivers, which consists in dispensing with the rotating spindles and bobbins for receiving the reduced fibre, and substituting cans from which the sliver is drawn on one side of the machine and delivered into similar cans on the other side.—No. 2039. February 9th, 1887. 8*d*.

Gas Engines.—*H. J. Haddan. (W. Gavillet & L. Martaresche, Paris.)*—This invention includes improvements in the cylinder, in the lubrication of the piston, in the arrangements for electrically igniting the gases, and in the introduction and evacuation of the gas. The first figure shows a longitudinal section of the cylinder, and the second an end view of the same. The fore

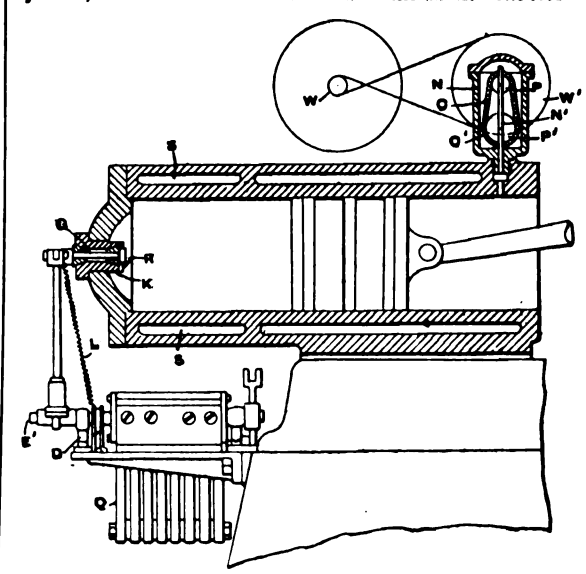

Fig. 1.

part of the cylinder has a cavity, through which circulates a stream of cold water, and in the hinder part a cavity S^1 serves to hold some non-conducting substance. The receptacle N contains the oil used by the automatic lubricator, and N^1 is a tube having a notch at its upper extremity and conducting the oil into the cylinder. A small brush O^1 fixed to an endless chain O^2 dips into the oil. This chain, by turning on a pulley P, conducts the brush before the notch of the tube, and leaves therein the necessary oil. The motion is imparted to a pulley W fixed on the shaft of the governor. The ignition mechanism

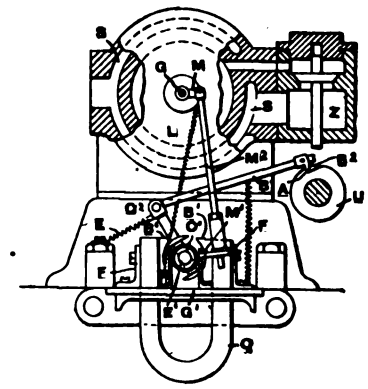

Fig. 2.

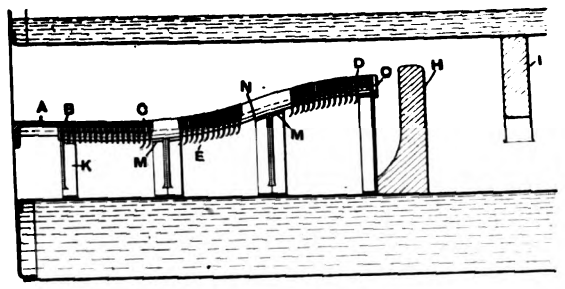
consists of a bundle of magnets Q, furnished at their extremities with poles B^1 of soft iron, and fixed to the bed plate G^1 by the bronze brackets F. Between these poles B^1 a bobbin C^1 revolves on the shaft E^1, having two poles united by a core of soft iron on which the induction wire is coiled. When the machine is at rest, the poles of the bobbin are attracted by the poles of the magnets. If the bobbin is made to undergo an abrupt rotary displacement, caused by the action of a cam V on the engine, an induction current is generated in the coil of the bobbin which gives the necessary spark for ignition. The generated current travels to the cylinder along the spring L, which also serves for actuating the shaft G through the crank M. This shaft is provided with a contact R, which is withdrawn from the bronze piece K by the movement of the bobbin. The disc U with the catch A serves to give the periodical displacement of the bobbin. There are seven claims.—No. 2194. February 11th, 1887. 8*d*.



Forging Circular Articles.—*C. Fairbairn, Sale, Cheshire, and M. Wells, Manchester.*—This invention relates to apparatus for forging articles of circular transverse section, such as balls or elongated projectiles, by subjecting them to rolling pressure between the faces of two oppositely revolving discs, shaped to the contour of the articles to be forged. One of the shafts on which the discs are mounted is slightly inclined, and is placed in a plane a little to one side of a plane passing through the axis of the other shaft. The faces of the disc are thus slightly eccentric and inclined to one another. By making one of the discs somewhat larger than the other, and thus obtaining a greater surface velocity, the blank is gradually advanced towards the narrowest part of the gap between the discs. The faces of the discs are grooved obliquely to radii. Two claims are made for forging apparatus constructed as described.—No. 1804. February 4th, 1887. 8*d*.

Rotary Engines.—*G. Dietz & E. Tamsen, Hamburg, Germany.*—A disc, on which two blades or pistons are placed at diametrically opposite points, is mounted on a shaft concentric with the cylinder. At opposite points in the circumference of the cylinder are placed two sliding gates, which divide the

Digitized by Google

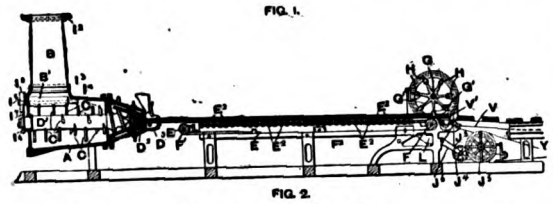
annular space in which the pistons travel into two parts. The steam is conducted to slide valves placed on one end of the cylinder, the valve rods, together with the sliding gates, being operated by means of a cam on the shaft of the engine. Each slide valve communicates with the annular steam space by openings on each side of one of the sliding gates. The piston disc is rotated by admitting steam above one gate and below the other, the other steam passages being used as exhaust ports. To reverse the engine the exhaust ports are used as steam inlets, and the steam inlets as exhaust ports. The sides of the blades or pistons are tapered towards the circumference of the cylinders, and the sides of the gates are tapered to a point inwardly. A tight joint is thus maintained between the gates and pistons as the former are withdrawn to allow of the passage of the latter. Packing rings are inserted in the sides of the piston carrying disc, for the purpose of making a steam tight joint with the cylinder ends. The inventors make four claims for the improvements in rotary engines described.—No. 15261. November 8th, 1887. 8*d*.

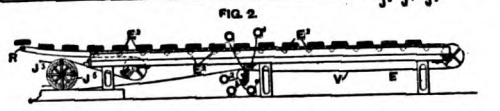
Boiler Furnaces.—*A. Schreiber, Dresden, Saxony.*—This invention involves some improvements in the construction and arrangement of the furnace bars. The figure represents a sectional elevation of the furnace fitted in the fire tube of a steam boiler. A is the ordinary dead plate; from B to C the bars are laid horizontally, and from C and D the bars are made to rise in a curve both longitudinally and transversely. The shape of the longitudinal curve will be seen in the figure, and

in the transverse section the middle portion of the bars rise to a greater height than at the sides. The lower edges of the curved bars are formed as at E to assist and direct the entrance of air from the ash pit; and horizontal grooves in the upper surface of the bars and vertical grooves formed on one face serve to provide distance pieces and air passages between the bars and on their upper surfaces. The bridge H is built in the flue so as to leave a passage for the supply of the necessary air to inflame the carbonic oxide; and for effecting a more complete intermixture of the heated gases, the inverted bridge I is also built in the flue, as shown. The fire bars are supported by angle irons K, the upper ends of which are fitted with brackets M. On these brackets are carried rails N which hold the bars. The fuel is laid thinly over the raised portion of the grate, and the smoke and unconsumed gases from the lower parts ascend to and mix with the flames from the more highly heated incandescent fuel in the centre. The four claims made are: (1) For the curved and arched fire bars; (2) for the lower edge E, and for the air channels formed in the bars; (3) for the means and appliances for supporting the fire bars; and (4) for the general construction and combination of the parts.—No. 14758. October 29th, 1887. 6*d*.

Brick Making Machines.—*C. Chambers, jun., Philadelphia, U.S.A.*—This invention includes several improvements in the construction of that class of machines known as the Chambers' brick machines. The diagram represents a general view of a machine made on the improved pattern, but does not show all the details of the mechanisms employed. The clay is dumped from a platform into the tempering case A, by way of a vertical hopper B. This hopper is formed with its base broader than its

FIG. 1.





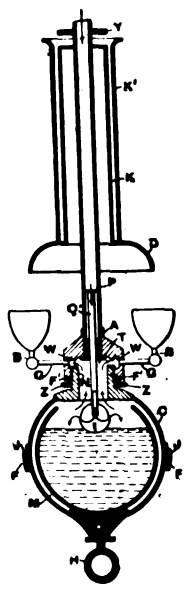


FIG. 2.

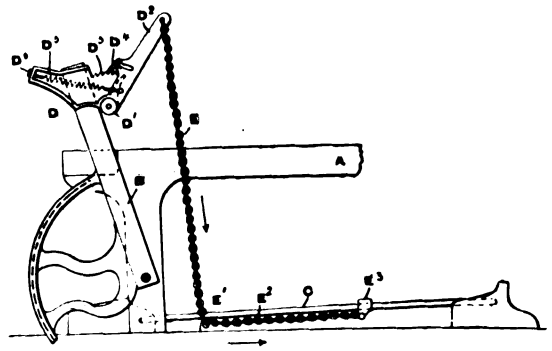
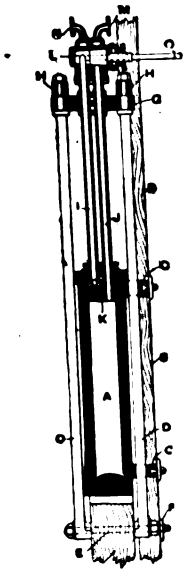
top, and its corners are rounded off so as to prevent the clay clogging. A feeding roller B^1 is placed in the tempering case, in order to make the passage of the clay easier. The pugging shaft D^1 is studded with tempering knives, the position of which on the shaft is designed somewhat differently from hitherto, with the object of obviating their tendency to hold the clay up and obstruct the feeding motion. The screw D forces the clay through the die D^2 and the sanding box D^3, whence it issues in the form of the long bar X. The belt E carries the bar along over supporting rollers E^2. These rollers, instead of being made of greater width than the belt, are, according to this invention, to be smaller than the belt and of the same width as the bar of clay. The principal improvement in the machine relates to the cutting off mechanism. The wheel G carries elastic bows H, whose function is to hold the cutting wire. In order to secure the rectangular shape of the extremities of the bricks, an arrangement of wheel and cam is introduced, but is not shown in the figure. The wire is formed somewhat differently by bringing over the end so that the straight converging sides form an acute angle, and by twisting the contiguous parts of the wire so as to form a long twist, and then winding a part of the end of the wire with a loose coil around the adjacent main portion of the wire. There are several other devices designed, one for cleaning the cut-off wires, another relating to the specific construction of the pulley F, and another relating to the slide plate for operating the cut-off regulator. A bifurcated frame O, secured to the under side of the longitudinal pieces, is used for supporting the return part of the off belt V. A bow clamp is introduced to afford a ready means of drawing towards each other the limbs of the elastic bows H, so as to allow of a quick attachment of the wires to their ends, and to replace broken wires with new ones whilst the machine is in operation. The device consists of a lever with a handle and arm, to which is hinged a double yoke, the lever and yoke thus forming a toggle joint. The inventor makes twenty-nine claims for these improvements and their combinations.—No. 6496. May 3rd, 1887. 1*s*. 3*d*.



Carburetting Gas Lamps.—*A. Kitson, Philadelphia, U.S.A.*—The object of this invention is to provide an easy means of replenishing the carburetting vessels, a simple regulating device which shall be automatic in its action, and a valve for shutting off the organic vapour from the atmosphere when the lamp is not burning. The gas enters the apparatus through the pipe P, to which is fitted the collar A. On the lower part of the collar is screwed the neck N of the carburetting vessel C. The supply pipe P is surrounded by a casing K, to which is attached the bell-shaped disc D. This disc is situated immediately over the burners B, and is used for bringing the heated products of combustion into contact with the pipe P. The vessel C is in two parts, which are joined at J, and may be unscrewed by means of the handle H. The interior vessel M contains the organic material used for enriching the gas; and the supply of this material is replenished by unscrewing C, and inserting a

new vessel M in place of the exhausted one. At the bottom of the supply pipe is fitted tightly a bushing T, through which the small tube Q slides freely. At the lower end of this tube Q is attached a float I. This float rests on the surface of the hydrocarbon, and serves to keep the tube Q always at the same distance from the carburetting material. As the material falls during its consumption the float and tube fall with it, so causing the gas to travel the same distance at all levels before impinging on the material. A regular amount of vapour is thus generated. The bushing T is drilled with several small holes, and by partially unscrewing it from the supply pipe an outlet for the gas is provided direct from the pipe to the burners through these holes. The quality of the enriched gas can thus be controlled. The screw in N allows for the shutting off of the gas from the burners. The neck of N comes in contact with the ring-shaped wedge W when it is screwed far enough up, so preventing the access of the gas and vapour to the pipes G when the lamp is not burning. The inventor makes thirteen claims for these improvements.—No. 12229. September 9th, 1887. 8*d*.



Expansive Gear.—*J. Tickle, West Bromwich.*—Two slide valves are placed one at each end of the cylinder in separate steam chests. On the back of each steam chest is a double beat valve operated by a cam secured to a horizontal shaft driven from the governor spindle by means of bevel gearing. The lifting cams are made with a quick termination to the lift to allow the valves to close suddenly, and to admit varying volumes of steam the cams are moved backward and forward. To effect this movement of the cams the governor spindle is hollow, and contains an inner spindle furnished with a rack on its upper part gearing, with toothed quadrants on the inner end of the governor arms. The inner spindle is thus depressed or raised, as the governor rises or falls. The bevel wheel which drives the valve operating shaft is loosely mounted on the governor spindle, and is partly rotated in either direction by the movement of the inner spindle. Three claims are made for the improvements described.—No. 2155. February 11th, 1887. 8*d*.

Mules and Twiners.—*W. T. Watts, Stalybridge.*—By this invention an improvement is introduced into the mechanism which effects the "nosing motion" of the winding-on apparatus. The figure represents an elevation of several parts of the self acting mule. A is the framing, B the ordinary radial arm and quadrant, and C the rod between the shaper plates of the usual shaper mechanism. To the arm B is secured a bracket D, which has a stud D^1 in it, forming the fulcrum of the lever D^2. This lever is the "nosing arm," and it carries a stud on one side for a bowl, which, when the arm B moves inwards, will come upon the ordinary winding on chain. On one side of the nosing arm a slot is formed for an adjustable stud, upon which a pawl D^4 is jointed; the free end of this pawl works upon ratchet teeth formed upon a segmental part D^3 of the bracket D. One end of a helical spring D^5 is secured to the arm D^2, and the other end is connected with a projection D^6 from the bracket D. The spring tends to draw the nosing arm towards itself, but the pawl resists the pull of the spring, and holds the arm D^2 in whatever position it is set. When the bowl at the end of the

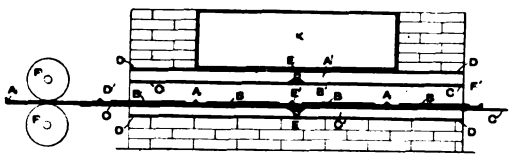
lever D^2 presses upon the winding chain, the strain upon the nosing arm is resisted by the pawl and ratchet, and as the cops build the spring is stretched more and more. An automatic arrangement for adjusting the apparatus as the cops grow larger is partly shown in the diagram. A chain E, one end of which is attached to the extremity of the nosing arm, passes through the eye of a bracket E^1 secured to the floor, and is fixed at its other end to an arm of a bell crank lever. A chain is attached to another arm of this lever, and to a collar E^3 adjustable upon the rod C. The chain E moves in the direction of the arrow as the cop builds, and the nosing arm is thus drawn down in opposition to the force of the spring. The inventor makes three claims: (1) For the combination of radial arm, nosing arm, pawl, ratchet, and spring; (2) for the combination of these parts with the chain E; (3) for the general arrangement.—No. 1786. February 4th, 1887. 8*d*.

Pile Driving Apparatus.—*J. Garvie, London.*—This invention consists of a method of introducing steam through tubular piston rods into the cylinder or monkey of a pile driver. In the accompanying diagram, A represents the monkey, and B the frame of the engine, along which the monkey moves up and down, being held in position by the slides C. The two rods D are fixed at the lower end to the pile by the bolt E, and the slide F keeps the pile in a vertical position. These rods are fixed

to the cross head G, and are provided with springs H to relieve the shock. The cross head carries two piston rods I and J, which are fixed to the piston K at the bottom, and are connected at the top with a three-way cock L. The opening M affords an inlet to the steam, and N an exit; O is a plug, made in two pieces, which regulates the steam in the cock. By turning the plug O, the steam is allowed to descend the rod I, and it discharges through the openings over the top of the piston, and thus lifts the monkey. Whilst this goes on, the exhaust steam escapes through J into the atmosphere at N. In the reverse motion, the steam descends through J, and the exhaust steam passes up through I, and escapes through N. This apparatus can also be used with hydraulic pressure. There are four claims.—No. 302. January 8th, 1887. 8*d*.

CHEMISTRY.

Dyeing with Aniline Black.—*W. J. S. Grawitz, St. Maur, France.*—Textile fabrics when dyed with aniline black present a brownish tinge, which is usually changed into a blueish tinge by the action of a hot soap bath. This soaping, however, renders the fibres greasy to the touch, and imparts a disagreeable odour to them. According to this invention, the brown tinge is eliminated by the following treatment: A bath is made of certain proportions of water, sulphuric acid, and sulphoricinate of soda, and the cotton is plunged therein. The fatty matter made by the action of the sulphoricinate on the acid combines with the aniline dye. The cotton thus treated is passed through an alkaline bath, and may afterwards be sized and dressed, and is quite devoid of smell. The inventor makes two claims, one for the process, and one for the new industrial product thus obtained.—No. 11182. February 5th, 1887. 6*d*.



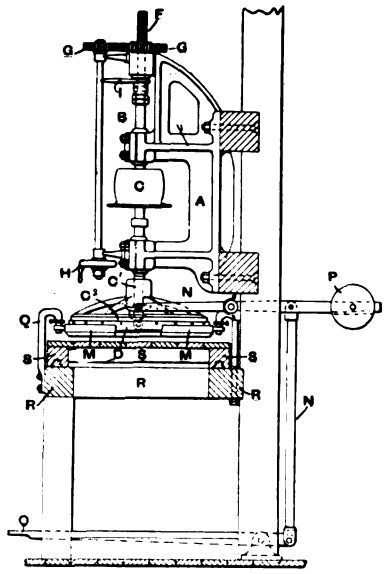
Digitized by Google

MANUFACTURE OF CAUSTIC SODA AND POTASH.—*L. Mond and D. B. Hewitt, Northwich, Cheshire.*—This invention consists of improvements founded upon the process included in Wise's Patent No. 4364 of 1882. In that specification is described a method for making caustic alkalies by heating their respective carbonates with oxide of iron in retorts. The improvement suggested is to use a very pure and fine carbonate of soda, obtained by heating the bicarbonate of soda produced in the ammonia-soda process to a temperature of 300°C., instead of the ordinary low test carbonate made by the Le Blanc process. This object may be advantageously effected by using a cylindrical furnace, revolving on a horizontal axis, and lined with fire clay blocks, in such a way as to form a number of projecting radial ribs. The material introduced into the furnace is lifted up by the projecting ribs to a certain height, and then falls through gases which pass along the furnace, so that the nearly pure carbonic acid formed in the interstices of the mass becomes replaced by the gases, and no longer hinders the progress of the reaction. The process can in this manner be completed in a few hours, and at a reasonable expense of fuel; and thus a great economy is effected, as well as an improvement in the manufacture of the alkali. There are seven claims.—No. 1974. February 8th, 1887. 6*d.*

COLOURING MATTERS.—*O. Imray. (Farbwerke vormals Lucius und Brüning, Hoechst-am-Main, Germany.)*—This invention relates to improvements in the production of alkylised diamidobenzophenonamine chlorides, and the conversion of these into alkylised diamidobenzophenones and yellow colouring matter of the class of the auramines. The patentee claims the production of mono and di-substituted amides of the dialkyl-amidobenzoic acids, by the action of aniline, orthotoluidine, &c., upon the chlorides of the dimethylamidodiethylamido-ethyl-methyl-amidobenzoic acid; the production of halogen compounds of the same by treating them with oxychloride of phosphorus and phosgene; the production of condensation products from these halogen compounds; and the production of tetra-alkyl-diamido-benzophenones from these condensation products.—No. 1694. February 3rd, 1887. 6*d.*

MISCELLANEOUS.

DECORATING GLASS.—*C. A. Durand & R. P. Engelmann, Paris.*—This invention consists of a modification in the processes of preparing and burning decorated glass. A suitable drawing on prepared paper, made with varnish, which is capable of resisting the attacks of fluoric acid, is sprinkled with rosin and fixed by means of gum on a sheet of glass coloured superficially. The glass is heated and the rosin thereby melted, and the paper is then removed with water. The glass is exposed to fluoric acid, and the printed parts retain their original colour, whilst the rest of the surface is eaten into by the acid. The explanation of the furnace will be effected by means of the accompanying figure, which shows a longitudinal section of the same. The cast iron or fire clay slabs A, supporting the painted or enamelled sheets

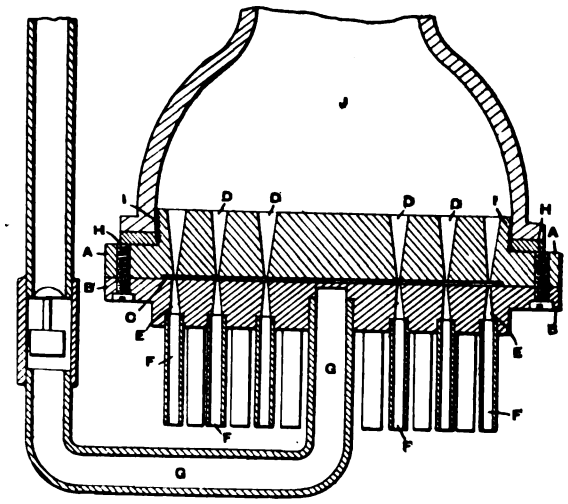


B, are advanced by the aid of a drawing mechanism shown at F. These sheets B pass between two other cast iron or brick slabs C, which are maintained at a sufficient heat for the fusion of the enamel. The middle space B^1 serves as a hot chamber through which the sheets pass one after the other, whilst the top and bottom spaces A^1 and C^1 admit the air to the flames at E, which are used to heat the furnace. The cold sheet enters at D^1, and is gradually heated during its approach to the middle E^1, and is again allowed to cool as it passes through the remaining part of the furnace. By this process panes measuring 8ft. by 7in. can be burnt in one hour. There are three claims.—No. 13723. October 10th, 1887. 8*d.*

COAL CUTTING MACHINES.—*T. Bower, R. W. Bower, & J. Blackburn, Woodlesford, and F. Mori, Leeds.*—These improvements refer to the employment of an electric motor for imparting motion to coal cutting machines generally. The motor is most conveniently placed on the frame work of the machine, and is of any approved form, while the electric motive force is supplied to it through suitable cables from a dynamo engine of high potential. A system of specially arranged gearing serves to engage the motor with the effective machinery of the coal cutter. Between the motor and the dynamo a cut-off motion is employed for the regulation of the speed of the motor, and consequently of the speed of the cutter. Though preferably the motor is placed in the frame work of the machine, it is also admissible according to the invention to place the motor at any convenient spot, and to allow the motion to be transmitted by belt or by static induction. The inventor makes one claim.—No. 1857. February 5th, 1887. 6*d.*

FEED WATER HEATERS.—*A. MacLaine, Belfast.*—The feed water heater which is the subject of this invention is formed of an outer shell or casing, inside of which is placed a hollow perforated cone, whose lower extremity is attached to the body of the outer casing. Inside this cone, and entering through its summit, is the perforated end of a steam pipe communicating with the boiler of the engine. Round the cone, and between it and the outer shell, comes the feed water from the hot-well, and it is drawn through the perforations of the cone in jets caused by the suction of the boiler feed pumps, which are connected by means of pipes to the bottom part of the outer shell. The steam supply intended for the heating of the feed water is conveyed to the inside of the perforated tube, and through the holes of which it expands outwards in jets into the space between the tube and the cone. The jets of steam and feed water there commingle, and an exceedingly rapid condensation of the steam supply takes place, and at the same time an effective heating of the feed water. An arrangement is also made for the extraction of the oil and air from the water. The sectional area of the feed water heater is made much larger than that of the feed water pipes, so that the water in the heater has time to settle, and the oil therein to rise to the top, before its passage through the perforations. A recess is formed round the inside of the upper part of the shell above the level of the entrance of the feed water, and from this recess the accumulated oil rises into a receiver placed at a higher level, and arranged with cocks, gauge glass, and fittings for drawing off the extracted oil at intervals. The air given off in the condensation also rises with the oil, and the receiver is provided with a cock at its upper extremity for releasing the imprisoned air. The claims made are three—for the arrangement of the heater, for the use of the receiver for extracting the oil, and for the combination of these two parts.—No. 3701. March 11th, 1887. 8*d.*

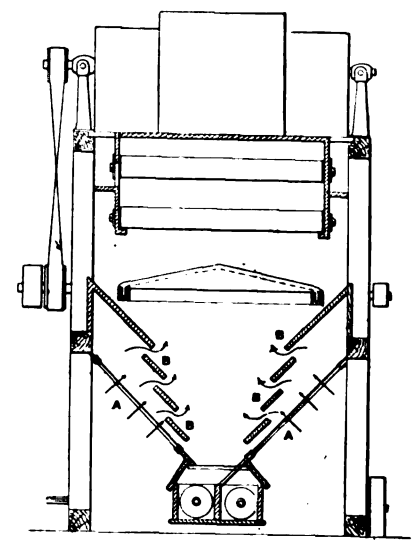
SAWING MACHINES.—*A. B. E. Nilsen & H. L. Mathiesen, Fredriksstad, Norway.*—This invention relates to the sawing machinery used in cutting the bottoms of casks and barrels, and has for its object the substitution of a circular sawing blade for the ordinary vertical blade, which moves all round the whole periphery. The circular blade is fixed round a rotating wheel of the same size as the ends or bottoms required, and the plane of this wheel is parallel to the material from which the piece is to be cut. The accompanying figure is an elevation of the apparatus constructed for the carrying out of this invention. A is a stand which is secured to a support, and mounted therein is a vertically rotating spindle B carrying a horizontal wheel C^2. Upon the circumference of this wheel the saw blade D is fastened by



screws. The spindle B is driven by the pulley C, and is raised or lowered by means of the screw F, the gearing G, and the wheel H. A fork I is provided, in order to prevent the screw F from turning with the spindle. The sledge S carries the wood to be cut, which is firmly held in its place by the ring M. This ring encircles the saw wheel, and is pressed against the wood by means of levers N, which are operated by the treadle O. The counterweight P is used to raise the ring, and a long staging R is placed beneath the saw. When the carriage with the wood thereon has been placed under the saw wheel, the workman depresses the treadle O, whereby the ring M is caused to press on the wood. As the saw rotates, the wheel H is to be turned so as to cause the saw to descend further into the wood. The inventor makes three claims.—No. 14403. October 22nd, 1887. 6*d.*

PISTON SPRINGS.—*G. Robson, Sunderland.*—This invention more particularly applies to spiral coil springs of any section used in the packing of pistons, and consists in corrugating the spring in the direction of the junk ring and the flange of the piston. The elasticity of the corrugations affords the necessary pressure to keep the piston rings against the junk ring and the flange of the piston. The inventor makes one claim for the improvement described.—No. 9394. July 2nd, 1887. 6*d.*

HUMIDIFYING AND VENTILATING APPARATUS.—*P. M. Justice, London. (G. Kesselring, Turin, Italy.)*—An air trunk or shaft is led under the floors of the rooms to be ventilated, and the rooms are connected to the trunk by means of pipes provided with ports. Outside the building, and connected at one end to the air trunk, is an underground conduit, the other end of which terminates in a well open to the air. To impart the desired humidity to the air, water jets or spraying devices are situated in the conduit. The water flows off into the well, the level of which is maintained at about the floor of the conduit. The air may be forced through the conduit and trunk by a fan or pump, and any suitable means may be employed for exhausting the impure air from the rooms. Four claims are made for the improved combined humidifying and ventilating apparatus described.—No. 14973. November 3rd, 1887. 8*d.*



PITCH CHAINS AND CHAIN WHEELS.—*H. Randhahn, Eisenberg, and F. W. Hering, Osterfeld, Germany.*—The improved pitch chain consists of links which may be rectangular or circular in section and shape. Some of the links are provided with pins which project laterally from either side. The chain wheel round which the chain passes has a central groove formed completely round the circumference. The perpendicular links fit into this groove, while the horizontal links lie upon rings surrounding the circumference and adjoining the grooves. The projecting pins fit between two rows of teeth formed all round the circumference, so that the chains are effectually geared to the wheels, whilst the teeth serve to guide the chain in its place. The teeth are made wider at their roots, so as to hold the pins upon the chain, and their points are so formed that the links readily leave them. Those of rectangular shape are preferable, as they fit better into the groove, and for large wheels the use of a considerable number of intermediate links between those provided with pins is advisable. The inventor makes five claims for these improvements.—No. 1788. February 4th, 1887. 8*d.*

VACUUM APPARATUS.—*W. L. Horne, Meriden, Connecticut, U.S.A.*—This invention includes several improved forms of apparatus for producing a vacuum by means of the frictional contact of the air with liquid. The vacuum is caused in two cases by a moving body of liquid, and in a third case by bringing the air in frictional contact with the liquid, whilst the liquid is kept stationary, and by moving the passages containing the air rapidly within the liquid. This third form is used in connection with a liquid reservoir, and requires power to operate it; and the first two forms require a liquid supply having a certain amount of pressure. In all these forms valves are dispensed with. The figure illustrates the mechanism employed in one of the first cases, and shows a vertical section of the vacuum pump. Of the two main plates, A is provided on its under side with a recess C, so that a space between them is insured when the plates are brought together; and tapering holes D are drilled in it, having their smaller diameter in the

lower face of the plate. The lower plate B is also perforated with holes E, which are so shaped that their smaller diameter is a short distance below the upper face of the plate. Their openings are to face the openings of the holes D, and are to be made of a slightly greater diameter. The plate B is also fitted with pipes F, which form continuations of the passages E; their function is to hinder the return of air once expelled through the tubes. The liquid is admitted through the enlarged end J of the supply pipe, and passes through the openings D and E, carrying with it some part of the air from the pipe G, which is connected with the vessel to be exhausted; and by a continuance of the flow of liquid, the vacuum can be perfected to any extent. The inventor makes twenty claims for the combinations in the three forms of the apparatus described in the specification.—No. 14539. October 25th, 1887. 11*d.*

MIDDLINGS PURIFIERS.—*H. Simon, Manchester.*—According to this invention several screens of porous fabric or of granules loosely arranged are placed in the passages by which the air is admitted to the purifier. In manufacturing towns the air is often laden with many impurities, such as soot, and the material under treatment thereby suffers some depreciation in quality and value. The object of this invention is to cleanse the air by causing the deposit of the vitiating constituents of the air on

these movable screens. The diagram indicates the position and arrangement of these screens. The air passes through the screens A, and is deflected and distributed by means of the obstructions B. The inventor does not limit himself to this particular sort of remover of impurity, and claims the application of any screen or dust catcher for the purpose of cleansing the air supplied to the middlings purifier.—No. 1461. January 29th, 1887. 6*d.*

Wire Nails.—*J. E. Emerson & T. Midgley, Beaver Falls, Pennsylvania, U.S.A.*—The lower portion of the improved wire nail is corrugated, and the outwardly curved surfaces are provided with barbs or projections to prevent the withdrawal of the nail. The upper portion of the nail and a small portion above the point are smooth and cylindrical. The die for forming the nail is constructed in halves, and contains the teeth or cutters for cutting the barbs or projections. Five claims are made for the improvements described.—No. 15246. November 8th, 1886. 6*d*.

Refining Hydrocarbon Oils.—*S. Pitt, Sutton, Surrey.* (*T. G. Hall, Chicago, U.S.A.*)—In carrying out the process embodied in this invention, a cylindrical converter is made use of, which may be provided with tubes or not, immaterially. The converter is preferably of a large size, about 10ft. in diameter and 30ft. in length, and is to be filled half way up with small pieces of granite. The still must be constructed so as to bear a temperature of 460°F. Into the bottom of the still, crude Canadian oil, together with a quantity of steam, is injected by means of a steam injector. In the presence of the highly heated blocks of granite at these temperatures the sulphur leaves the oil, and in the form of sulphuretted hydrogen passes into the water, where it can be detected by the usual tests. The vapours of oil and water are condensed in the ordinary way, and the oil and water are separated by gravity. Other materials besides granite may be used in the purification, such as quicklime, marble, and cryolite, all of these substances being effective agents in the removal of the sulphur from the crude oil. The inventor claims the process of manufacturing hydrocarbon oil, which consists of subjecting the mingled vapours of oil and water to extensive converting surfaces of some such material as mentioned at a high temperature, and in condensing the said vapours.—No. 15256. November 8th, 1887. 4*d*.

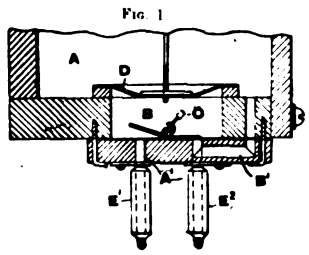
GERMAN PATENT ABSTRACTS.

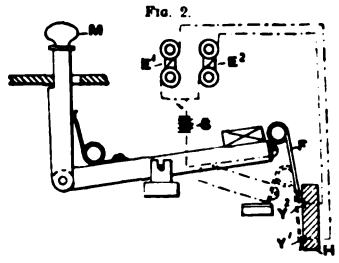
Gas Motors.—*Jacob Faber, Elberfeld.*—The mixture of gas and air passes through the valve E into N, and is forced by the pump D through the valve F into G. From there it enters the combustion chamber behind the pistons of the cylinders A, arranged round the shaft M, and is there ignited. In order to obtain a

mixture of gas and air when starting the engine, the space G is partly filled with water, the remaining space being occupied by air. Now the valves W and X are opened, the former admitting gas into G, the latter discharging the water; thereby the space G is filled with a mixture of gas and air, which is easily ignited.—No. 41483. September 17th, 1886.

Organs.—*Brauner Bros. & F. Drexler, Vienna.*—The iron valve B is pivoted in the centre and has a weight C attached to it. B closes either pipe A^1 or B^1 according to an electrical circuit being

Fig. 1.





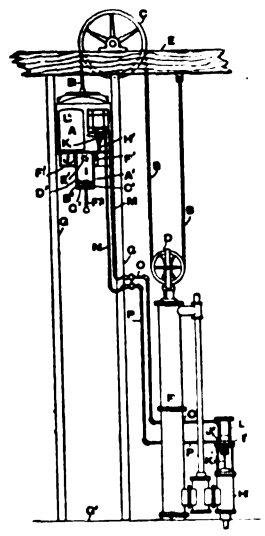


Fig. 2.

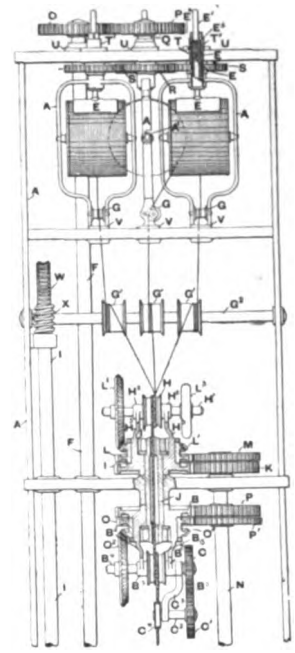
established in the electromagnet E^1 or E^2. The pipe A^1 leads into the open air, whereas B^1 connects the wind chest A, constantly filled with air, with the space under the diaphragm D. The closing of the electric circuit in either E^1 or E^2 is effected by moving M up or down, and thereby sliding the spring F over the contacts Y^1 and Y^2 fastened to H, and connected to the electromagnets E^1 and E^2 by insulated wires. The other ends of the magnet's coils are connected to one pole of the battery S, while the other pole is connected to the spring F.—No. 41610. October 14th, 1886.

UNITED STATES PATENT ABSTRACTS.

Elevator.—*C. G. Otis, Brooklyn, N.Y.*—This invention consists of a device for starting and stopping elevators by operating on the valve of the motor from the interior of the car by means of compressed air. In the diagram A is the car, B its supporting rope, which goes over the pulley C and under the pulley D. The latter pulley is fixed to the end of the piston rod of the apparatus F, which supplies the motive power. The valve H controls the

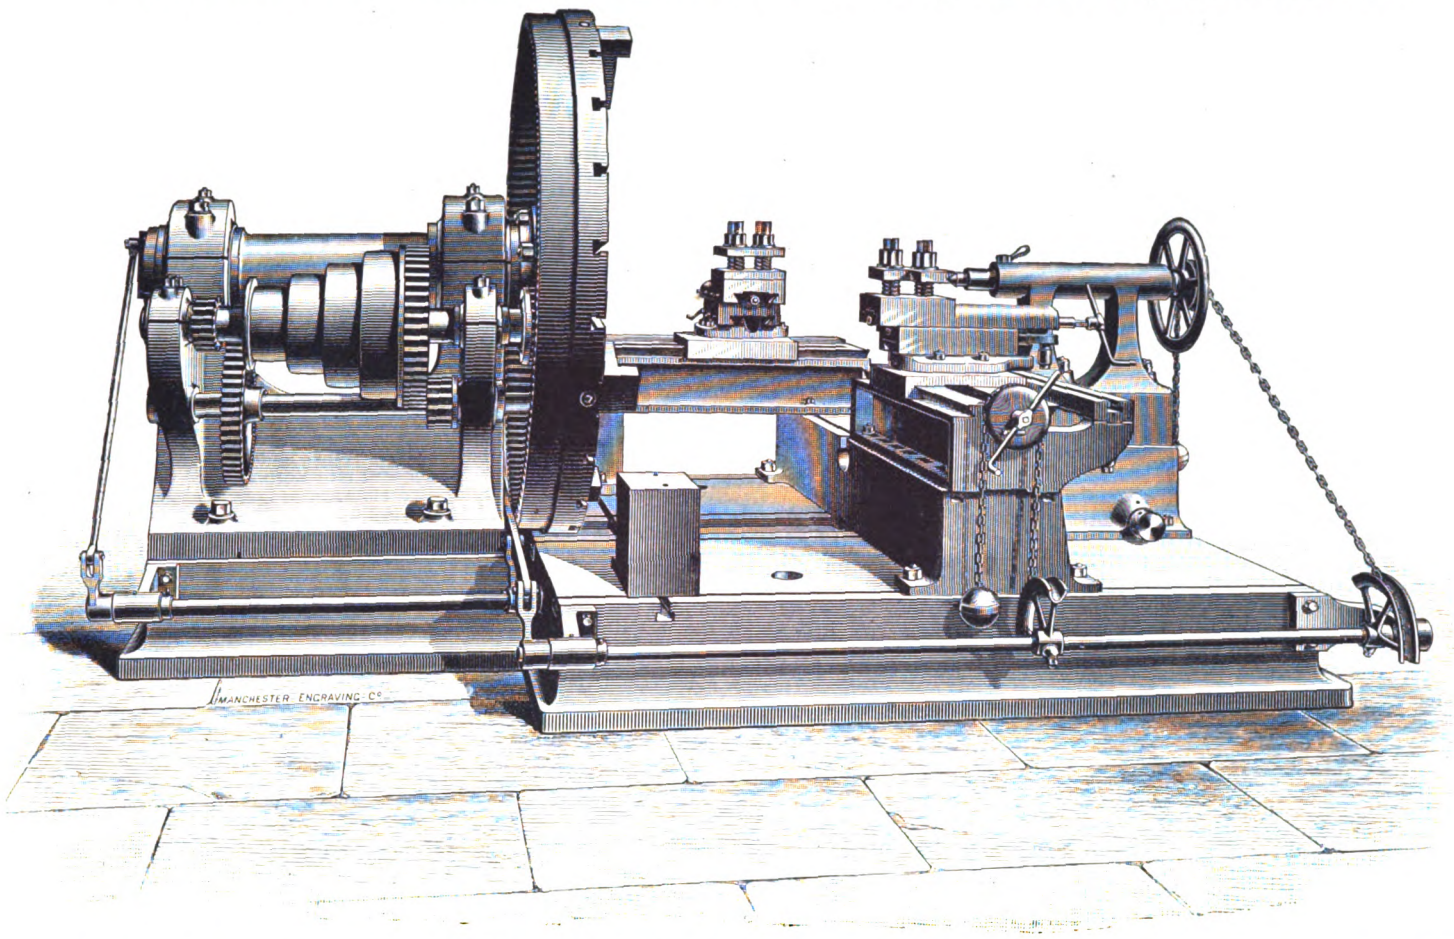


passage of the fluid into the motor F. At the bottom of the car A is an air pump I of any convenient construction. Its piston B^1 is provided with openings C^1, which carry flap valves D^1. The piston rod F^1 is of short length. At the upper end of the cylinder are openings E^1 into an air chamber J, and they are closed by flap valves F^1. A pipe H^1 leads from the chamber J to a valve K, which is operated by a lever L^1 projecting into the interior of the car. From this valve branch out the two flexible pipes M and N, which communicate with the valve operating device L. When the car has reached its lowest position G^1, the piston B is forced up the pump I, and the air therein is compressed into the chamber J. This air can be used to move the piston J^1, either up or down, by means of the lever L^1 and the cock K, and the pipes M and N. The car can thus be started or stopped by a person inside it. The inventor makes four claims for the apparatus described.—No. 369297, dated 30th August, 1887.

Cop Tube Machines.—*F. Moss, New York, and R. Cook, East Newark, New Jersey.*—Improvements are here introduced into the machines for making spirally wound paper cop tubes of the kind used for spinning yarn on mule spindles. The improved machine is mounted on a frame in which is journalled a driving shaft. The shaft carries two pulleys, one fast and the other loose, and two geared tooth wheels, which drive by means of intermediate mechanism the cop tube spindle and the paste distributing band respectively. The cop spindle is conical in form and rotates rapidly, and the tube produced tapers externally and internally. The paste distributing band is so arranged that it may be pressed against and withdrawn from the spindle at pleasure by means of an arm and lever. An automatic arrangement for starting and stopping the machine consists of a spring pressed rod and a cam secured to it, together with a shipper bar and its spring. A throwing off device is also included in the invention. An arm or bracket slides longitudinally on the cop tube spindle, and is connected at one end to a bar, which is held in position by a spring. The arm of the bracket is actuated by a mechanism connected with the starting and stopping apparatus. A strip of paper is held by the operator, who introduces it between the spindle and the belt. The paper is wound on the spindle, and is formed into a solid mass by the paste. By the movement of one handle by the operator, the machine is stopped, the belt withdrawn from the spindle, and the cop tube forced off. The inventor makes three claims for the combination of rotary spindle, paste distributing band, automatic belt shipper, and throw-off mechanism.—No. 373566, dated 22nd November, 1887.

Boiler Furnaces.—*J. Bowe, Chicago.*—The object of this invention is to secure an even and regular draught, and to supply automatically the suitable and necesary quantity of air for the economical combustion of the fuel, and also to provide a means for the completion of the combustion of the gases before their entry into the flues. For the furtherance of the latter object, a bridge wall is built at or about the height of the grate, and is carried back to the rear of the furnace. A raised portion of this wall is in the form of an inverted arch, and is provided with combustion flues and an annular space between it and the boiler. This space permits a portion of the heat to pass between the boiler shell and the bridge wall, so that the boiler is heated throughout its entire length. The bridge wall, being built back to the rear end of the furnace, fills the space usually employed as a combustion chamber, and prevents the formation of eddies in the draught. Opposite the flues which penetrate the raised part of the bridge wall, and just over the furnace doors, are tubular openings in the furnace shell, for the purpose of admitting air into the space above the grate. The ends of steam pipes are led into these openings, and the discharge of steam from these serves to inject the necessary air for the proper combustion of the gases given off in combustion. The supply of this air is regulated automatically, and it is so arranged that most air shall enter directly coal has been added, and that the quantity shall decrease as the combustion proceeds. A small vertical cylinder or dash-pot is suspended on the outside of the boiler, and is filled with oil or water. The piston which fits it has a small hole in it, covered with a flap valve, and the piston rod is weighted and enters the lower end of the cylinder. This piston rod is connected with a valve in the steam pipe, which supplies the steam for the injection of the air, and also with a secondary swinging door of the furnace. The mechanism is so arranged that, when the door is opened and coal put on, the piston is raised to its greatest height in the dash-pot, and the secondary door is opened to its utmost extent to allow of the freest possible entry of air to the grate; at the same time the steam cock is opened and the jet of steam injects the air into the space over the grate. Afterwards the piston gradually slides down the dash-post by reason of the weight attached, and automatically shuts the steam cock and the secondary furnace door, thus decreasing the draught. Eight claims are made for the combinations of parts.—No. 371872, dated 18th October, 1887.

Rope Making Machine.—*T. B. Dooley, Boston.*—This is an improved machine for twisting the strands together with uniform tension throughout the entire length of the rope. The shafts F I N have motion communicated to them by means of bevel gears from a prime mover not shown in the diagram. The shaft F, together with the gear wheels O P R and S S S, transmit their rotation to the fliers A, which carry the spools. E represents a saddle constructed to rest upon the twine on the spool, and fit thereover when the same is full. Extending up from the saddle and through the hollow spindle T of the fliers is a rod E^1, having a pin E^2 secured therein a short distance below its centre. T is provided with a bushing E^3, which has a diameter sufficient to permit a spiral spring E^4 to surround the stem E^1. This spring bears upon the pin E^2 and upon a shoulder E^5 on the nut T^1. The saddle E is thereby pressed downwards on the twine, causing a tension in the strands as they are drawn off; and when the bobbin becomes empty the resilient force of the



spring relaxes, and the tension is lessened, thus compensating for the increased strain necessarily exerted on the strands to turn the spools when the radius becomes smaller. The strands are then led over the pulley G, and the rotation of the fliers tends to twist them. The twisted strands proceed over the wheels G^1, which are turned by the action of the worm and wheel X and W. The mechanism shown in the lower part of the figure is intended for the union of the strands and the formation of the cord. The shaft N, carrying on it the gear wheels M K P^1 P^2, transmits motion through these wheels to the wheels L^1 I^1 B O^2 respectively. It is so arranged that the shaft H, carrying the flier spool H^1, shall rotate by means of the bevel L^2, and at the same time its bearings H^2 revolve through their connection with I^1. The toothed gear K is provided with one less tooth than M; and the arrangement of the gearing B and O^1 is similar to that of M and K. The twisted strands are taken up and fed forward to the rope flier spool H, where they are laid up into a rope by the revolving head, through the motion imparted to it by the gear wheels on the shaft N. The inventor makes eight claims for these improvements.—No. 373800, dated 22nd November, 1887.

AN IMPROVED FACING LATHE.

CONSTRUCTED BY MESSRS. HETHERINGTON & CO., ENGINEERS, MANCHESTER.

AN IMPROVED FACING LATHE.

WE illustrate above an improved facing lathe recently constructed by Messrs. Hetherington & Co., and specially designed for use in a general engineering establishment. The face plate, which is 7ft. in diameter, is fitted with a four-jawed chuck, and revolves on a cast iron spindle having a 10in. neck. The face plate is driven by means of an internal toothed wheel into which a pinion gears, and the machine can be either used with single, double, or treble gearing, and is therefore of a powerful type. The slide rests are two in number and are compound, being fitted with self acting feeds. They are carried by a saddle extending across the bed plate, and are arranged so that they can be swivelled when required for longitudinal sliding. For this work the rest is arranged as shown in the illustration, and it may be noticed that its free end is sustained by a pillar placed conveniently near to the face plate. The rests can be also arranged to follow a former when curved or profile is required. The loose head stock is also arranged as a boring head and fitted with a self acting ratchet feed, this being very convenient in many instances. A fly wheel for instance could thus have its rim faced and surfaced or its boss faced, while the latter was being bored. The lathe is provided with a very massive bed and is strongly designed throughout. It weighs altogether about 12 tons, and is well finished, and the workmanship throughout is of a high class character.

NEW MALTING AND SCREENING MACHINERY.

ONE effect of the abolition of the duties on malt has been to increase the trade in foreign barley. The hampering effect of the Excise restrictions, by which everything in connection with malting was done under stringent rules and regulations, prevented any experiments in the use of what may be briefly described as Eastern barleys or barleys grown in a hotter climate than that of the temperate regions of Europe. These barleys all swell when wetted considerably more than English, French, and German barleys. Hence the maltster using these dry barleys would find himself mulcted in higher Excise duties than on English grown barley, since the duty was always levied by measurement after the grain was wetted or steeped. The duty being now abolished, the maltster is free to import his barley from any quarter he may think fit, and accordingly the trade in barleys imported from France, Germany, Denmark, the Danubian provinces, and the Eastern countries already referred to, has largely increased. The trade with the latter countries is, however, the most important. This development in the foreign barley trade places maltsters situated on the coast or on a navigable river at a great advantage over those in our inland towns. Hitherto most malting has been done in the inland towns, such as Newark, Grantham, Burton, Lichfield, and other towns —proximity to the barley grower being of importance. Now this consideration is of less importance than formerly, and when foreign barley is used for malting purposes in the inland towns, the question of railway rates for transporting the grain is a serious item. The maltster on the coast can ignore this question. He can receive his barley from all countries direct into his granaries, and is in a good position for delivering his malt to all brewers in easy reach of the coast.

We recently had an opportunity of inspecting some extensive new maltings and screening machinery, which have been erected by Messrs. Free, Rodwell, & Co., at Mistley, Essex. This town is favourably situated on the navigable river Stour at a distance of 10 miles from Harwich, and steamers of 500 tons burden and sailing vessels of 350 tons can be unloaded at Mistley. Messrs. Free, Rodwell, and Co. unload the imported foreign barley direct from the ship's hold into their granaries. In addition to having facilities for dealing with foreign barleys, this firm have railway sidings in all parts of their works in direct communication with the Great Eastern main line, so that they are in a position to receive English grown barley or to dispatch malt by rail to all inland towns. The malt from Smyrna barley is fast growing in favour with brewers, as it possesses some properties which have a more rapid fining effect upon beer than English and many other barleys, the effect being that the process of brewing can be finished two days earlier than with English barley. This is an advantage of no mean importance to brewers in large towns where space is valuable, and London brewers especially appreciate the advantage greatly, as they can deliver beer to their customers within six to seven days from the commencement of operations. Thus one effect of the abolition of the malt tax, by encouraging the use of Smyrna barley, is to enable the London brewer to turn over his capital more quickly than formerly. Unfortunately Smyrna barley, as imported, has serious defects. From the slovenly habits of the cultivators of the soil, tares, grass, and other seeds are abundantly mixed with the barley, and the rude method of thrashing by oxen on an earthen floor contributes dirt and rubbish to further deteriorate the quality of the barley. These defects are well known to dealers in barley, and have checked the probably more rapid increase in its use. Good cleaning machines are a desideratum if Smyrna barley is to be used for malting purposes. Hitherto agricultural implement makers have designed their screening machinery with a view to its being used upon English grown barley, or at any rate for barley grown by farmers who take the trouble to keep their land clean and free from tares, and who use thrashing machines of some description or other.

Messrs. Free, Rodwell, & Co. appreciating the fining properties of Smyrna barley, and the probable rapid increase in the trade, have, after one or two experiments, put down a most complete set of screening machinery. After passing through the screening machinery, the barley is as clean as the finest English grown sample. The machinery has been constructed by Messrs. Vangelder, Apsimon, & Co., of Sowerby Bridge, and is capable of cleaning 200 bushels per hour. Briefly described, the barley passes through two sets of machines. The first, known as the "Victoria separator and eccentric grader," does the rough work, separating the sample into coarse refuse, large tares, and three grades of barley. This machine is, in principle, a series of five reciprocating sieves, with different sized perforations. These sieves or screens deliver at different spouts, the material passing over them, and are worked from an upright shaft by eccentrics and connecting rods. An exhaust fan acting on the barley sucks up any fine dust or light grains, and delivers the refuse which collects in an enlarged pocket of the main pipe by a spout into sacks. The exhaust can be regulated by a movable sluice to any degree of suction. It can readily be understood that simple sieves will not extract broken or half corns, nor tares of a diameter equal to that of the barley. This machine alone is, therefore, insufficient to do the whole of the work, and the final cleaning is done on other machines, consisting of six pairs of cylinders, each about 2ft. diam. and 8ft. long. The cylinders are arranged in pairs, one over the other, the upper cylinder acting as a separator to extract the smaller tares and half corns from the whole barley, and the lower as an ordinary screen. The upper cylinder is not perforated, but covered with hemispherical indentations smaller than the length of a grain of barley, though larger than a half grain. Hence the half grains,

Digitized by Google

tares, and other seeds left from the first machine fall into the indentations or recesses, and are carried round in them until they fall into a trough below, in which an endless screw works, and delivers into sacks at the end of the machine. The whole grain barley, which is thrown against the side of the upper cylinder above its horizontal centre line, is kept from going round with the cylinder by a series of scrapers, resting on the cylinder as it revolves. The full grains, of course, cannot fall completely into the recesses in the cylinder, and anything projecting from the recesses is pushed out by the scrapers, and by them conducted into the feeding trough to be presently described. The barley is fed to the different cylinders by an endless screw working in a trough at the ends of the cylinders, and at right angles to them. In this trough are openings delivering the grain into the cross or feeding troughs, one to each upper cylinder. In these cross troughs revolve blade propellers throwing the corn, as mentioned above, against the revolving cylinder in an oblique direction. The barley is thus being continually thrown up by the blades and returned to the trough by the scrapers, and at the same time gradually advanced by the oblique action of these blades. In this way the seeds and half corns are gradually separated as the barley travels along the trough and cylinder. The barley passes then through the lower or screwing cylinder, where it is acted upon by a second exhaust fan to draw off all light corns and other refuse which is useless for malting purposes, and which had escaped the action of the first machine.

The foreign trade in barley is capable of great increase, and it is therefore of importance for a maltster to be alive to the necessity of being supplied with the most efficient screening machinery able to deal with all classes of barley, from the Smyrna with its heterogeneous rubbish to the best English, in which only broken corns have to be taken out. This year the crop of English barley is deficient, and this deficiency must be supplemented with supplies from abroad. Hence efficient screening machinery is at the present moment of considerable importance. It must, however, not be supposed that screening machinery is only useful on foreign barley. In a very dry summer English barley is brittle and easily broken in thrashing. Broken barley is useless for the brewer, and the machinery above described could, with advantage, be used for separating these half corns even in English barley. The improvements in screening machinery just described may be said to be due to the abolition of the malt tax, a result probably not contemplated by the introducer of the Bill.

THE INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting held on the 10th of January, the paper read was on "The Use and Testing of Open Hearth Steel for Boiler Making," by the late Mr. Hamilton Goodall, Assoc. M.Inst.C.E., which gave the experience of the author in the use of open hearth steel for boiler making since the year 1875, and described numerous experiments to ascertain the cause of the difficulties met with in working the plates. To avoid spoiling a plate by taking pieces from it for the purpose of testing, a drifting test was adopted, in which washers were prepared from the material removed from the plates in making rivet holes, and drifted in a special machine to the bursting point by means of a series of drifts having a taper of $\frac{1}{4}$in. in 5in. In the majority of tests the washers were drilled out at right angles to the surface of the plate, but in some cases they were drilled out parallel to the surface; the outside diameter of the washers was $\frac{1}{16}$in. with a drilled hole $\frac{1}{4}$ (0·234) in. in diameter. Tests were also made to ascertain the load on the drift necessary to break the washer, and to establish some relation between the elongation of a washer and the elongation in a length of 8in. of plate. Preliminary tests, with washers cut from shell plates, having an average tensile strength of 26 tons per square inch, gave an average drifting diameter of 0·645in.; from back tube plates and furnace stiffening rings it was 0·644in., corresponding to an extension of 27 per cent. in 8in. These sizes were taken as the normal diameters for a good plate. The investigations of the author were specially directed to obtain a solution of the difficulties experienced in using steel plates, and included experiments on the welds of furnaces, the effects of hammering, of compression, of punching and shearing, of flanging, of annealing, and tests of defective plates. With respect to welds of furnaces, tests were made with washers taken from five stiffening rings, flanged after welding; three of them were good welds, and gave an average drifting diameter of 0·447in.; the diameter of the other two was only 0·328in.; a diameter of 0·406in. was considered to indicate a fairly good weld. In a further test of washers from another stiffening ring $\frac{1}{2}$in. thick, the diameters varied from 0·625in. to 0·312in., the elongation being reduced to about 3 per cent. in 8in. This plate manifested no outward signs of being damaged. Tensile tests proved that heating the ends of shell plates and hammering to the required curve for butt straps or lap joints was, in some cases, injurious, the elongation having been reduced from 28 down to 6 per cent. in 8in. The plates were then set up cold, as tensile tests indicated that apparently no harm was done by this. But a number of drifting tests soon showed that the effect of cold hammering was to reduce the ductility of the material; the extent was equivalent to an average loss of elongation in 8in. of from 5·01 to 7·89 per cent. Nor did annealing restore the ductility, as in all cases annealed washers from the unhammered part of the plate gave a larger drifting diameter than from the hammered part. Cold hammering was therefore also abolished, and all bending was done in the rolls. Drifting tests of washers taken from a flanged end plate, which cracked in riveting, were given. These showed considerable irregularity in the quality of the material, the results leading the author to believe that steel was distinctly inferior to iron in its ability to resist the effects of heating and hammering, which he attributed to an absence of homogeneousness. Compression did not seem to be injurious. Drifting tests were made with washers cut from burrs punched out of plates, and from plates squeezed up in a hydraulic riveter under a pressure of 20 tons per square inch. The thickness of the burrs had been reduced by the compression from $\frac{13}{16}$in. to $\frac{3}{4}$in., and that of the plate from $\frac{13}{16}$in. to $\frac{3}{4}$in. and $\frac{23}{32}$in. The drifting diameter of the former was 0·614in., and of the latter 0·687in.; hence it was concluded that compression up to 20 tons per square inch was not injurious. With regard to punching and shearing, experiments were made to determine how much it was necessary to chip off the edge of a plate so treated to prevent its cracking when stretched in flanging. Washers were taken from near the punched and the sheared edge, and from the solid part of a plate. The result was that the average drifting diameter of washers cut out at $\frac{1}{32}$in. from the edge was a little less than from the solid plate; hence an amount of $\frac{1}{32}$in. was all that was necessary to remove from the edge of the plate. When a piece of $\frac{3}{4}$in. plate was flanged to a right angle, with a 3in. inside radius at one end, diminishing to a square corner at the other, washers drilled out of the top of the radius and tested showed from their drifting diameters that a large radius was preferable to a small one; but that even with a large radius the inside suffered from the compression to which it was subjected. The drifting diameter of washers taken from the corner of a shell plate, which cracked while being thinned under a steam hammer, varied from 0·5in. to 0·687in., representing a difference of elongation in 8in. of from 15 to 31 per cent. This method of thinning corners was therefore abolished, where practicable, in favour of scarfing them in a machine, although further tests of washers cut from plates worked in both these ways gave results almost identical. A plate overheated through flanging was found not to have sustained so much harm as might have been expected. The author specially wished to direct attention to the following points: (1) Was a steel plate damaged by local heating? (2) If damaged, was it restored wholly or partially to its original strength and ductility by annealing? (3) Had tests been made to determine these points; or, if not, were any results published to show that a certain percentage of steel plates had failed, while, under precisely the same conditions, the percentage of failure with annealed plates had been less? From numerous tensile tests of plates unworked and locally heated, it appeared that sometimes the breaking strain was apparently increased by annealing, and sometimes diminished, the majority being in favour of the latter; with the elongation of the tensile and drifting tests, the reverse was the case. Drifting tests were made with washers cut from the saddle plate of a furnace, from a top back shell plate, and from a furnace stiffening ring flange. In the former, the average tenacity and ductility were reduced by annealing, while, in the latter, the results with annealed and unannealed washers were practically identical; from this it did not seem that there was any advantage in annealing plates. With regard to the effects of heat, and respecting defective plates, the results of tensile and drifting tests, taken from a back tube plate of special quality mild steel, an ordinary back tube plate, a middle back plate, and a top back plate, which cracked or otherwise failed in working, showed in some cases considerable drifting variation, and much irregularity in the ductility of the material. A diagram was given of the possible combination of contiguous particles in a plate, as represented by the equivalent elongation in 8in. In the opinion of the author the want of uniform ductility was the only remaining difficulty in the use of steel plates, and one which steel makers might remove, if they could, by a thorough mixing of ingredients, make a homogeneous material; he believed if this were done little more would be heard of cracked plates. Finally, the author stated the results of tests of plates of a higher tenacity then generally used; but the plates had not been specially prepared, and did not represent the best results obtainable. He suggested that if steel makers could increase the thickness of ingots, and improve the homogeneity of the metal, there was little doubt but that plates of much higher tenacity could be used than at present. Probably in addition to the special mild steel for the plates of furnaces, and the other quality, which was the same for flanging purposes and for shell plates now in use, it might be possible for steel makers to introduce a third quality for shell plates only, and by gradual steps to obtain a considerable increase of tenacity of the material. At the same time, a uniform width should be specified for the samples tested, and some stipulations made as to the minimum proportion to be allowed between the breaking strain and permanent set. From figures supplied by Mr. E. D. Leavitt, jun., of Cambridgeport, Mass., of tests of steel boiler plates, the average elastic limit was equal to 70 per cent. of the average breaking strain; whereas, in specimens tested by the author, it had been as low as 48 per cent., and had never exceeded 66 per cent. The paper concluded with a record of the experience of the author in regard to rejected and spoilt steel plates for boiler making as compared with iron since 1875; the failures in working, and from defective plates, being greatly in favour of steel.

MODERN MACHINE TOOLS.*

Before commencing his address on the above subject, Mr. Dixon first thanked the members for electing him president, and remarked that being better acquainted with the construction of machine tools than any other branch of engineering, he had chosen this for his subject. He then went on to say that it was not necessary to go far back to find a time when machine tools, beyond the foot lathe, the drilling machine, and a rude apparatus for boring cannon, did not exist, or if existing, were of the most primitive form. Watt found in the year 1764 that some of his greatest difficulties arose from the absence of any machine where-with to do some parts of the work, his chief one being the necessity for some means of boring cylinders. With his first engine cylinder he had differences of diameter to overcome, so much as $\frac{1}{8}$in., and it is said that its piston remained leaky though he packed it with "paper, cork, putty, pasteboard, horse dung, and even old hat." When he at last got one bored, he was so pleased that he wrote one of his friends, and said that "he had his cylinder now bored so perfectly that you could not get half a crown between the cylinder and the piston anywhere." The necessity for the accurate construction of steam engines gave rise to many inventions, and the history of the development of machine tool making explained why Manchester became such a centre. It seems to have been in the workshops of Mr. Joseph Bramah, of London, that attention was first systematically given to the construction of machine tools. In the year 1795 Bramah invented the hydraulic press, and had doubtless felt the very keen demand for means of accomplishing many desired mechanical constructions. In addition to the hydraulic press, with which his name will ever be associated, he gave very considerable attention to machine tools. Being the inventor of a new lock, he found it necessary to devise a series of special machines for their manufacture, and it was on this work where a revolving cutter or milling tool was probably first employed for producing plane metallic surfaces. About the year 1802 he brought out many improvements in tools, and it was in his workshop about this time that Maudsley, his foreman, first introduced, if not actually invented, the slide rest; an invention which more than any other has undoubtedly advanced the construction of mechanism to its present efficiency. Although it was probable that the slide rest was in use in France to some extent before Maudsley's time in England, it is not likely that he knew what was being done in France, although he may possibly have seen a model of one introduced into England from Holland. Joseph Clement succeeded Maudsley as Bramah's foreman, and on the death of the latter, in 1814, commenced business on his own account, employing only about thirty men of the highest class, one of the chief being Whitworth. Clement largely improved the slide lathe, and invented that exceedingly perfect and beautifully simple contrivance known as the "Clement" driver. A noted group of men of the last generation sprang from these workshops, including Roberts, Muir, Lewis, Nasmyth, and Whitworth, Roberts being the inventor *par excellence*, whose fertile brain was ever ready to pour out new designs and invent to order, while Whitworth duly recognised the fundamental importance of mechanical accuracy in machine tool construction, seeing clearly that machine tools being simply instruments for reproducing upon objects some essential part or parts of their own construction, it was absolutely essential that they should be perfect. While Watt, in 1769, rejoiced that his cylinder was so well bored that he could scarcely get a half-crown piece between the piston and the cylinder, Sir Joseph Whitworth, in 1840, produced cylinders and pistons so perfect as to differ by less than one-millionth part of an inch in diameter. Reference was then made to the work of Sir Joseph Whitworth in establishing a true plane, standard measurements, and screw threads, the latter at present being gradually adopted as a standard on the Continent of Europe. In considering the fitting of a well equipped establishment, adapted for general engineering work, reference was made to the foundry and the great advances in lifting plate and wheel moulding appliances. Mr. Dixon mentioned a curious practice he had met with in a Belgian workshop, which was, he believed, the only place in the world where moulds are made from drawings only, or more correctly without patterns, and these not simple ones, but extremely difficult ones. The castings seemed perfect in every respect, and he was assured by one Corliss engine builder who had all his castings made by this process that there was distinct economy in it. He simply sent his drawings to the foundry, and had made no patterns whatever since its adoption. The development of the smithy tools, beginning with the steam hammer invented by Nasmyth in 1838, and ending with the hydraulic forging machines of Whitworth, was next mentioned. The class of cold and hot saws and mechanical hammers were also mentioned, and the author then passed on to consider the subject of planing. The planing machine was entirely the development of the present century, and about its origin an exceedingly hot controversy had raged. It was very probably developed by several people; but it certainly existed in a fairly perfect form about the year 1820, in the works of Fox, of Derby, widely noted for his excellent productions in textile machinery and tools. The first publication having reference to it was in 1825, when Clement, of London, received the award of the Society of Arts for his machine. From the table driven by a chain and running on numerous friction rollers it was by Whitworth much improved, as he recognised the vast importance of accurate slides. The forms of these slides were originally vees, or one vee and one flat, and these vees, after gradually increasing in the angle, have steadily approached, and have now in the most improved machines become flat slides. These, with vertical guides to prevent the lateral motion of the table, are capable of taking heavier cuts with the same strap power, the vertical guides preventing the possibility of the table yielding when taking heavy side cuts. For most ordinary dimensions of objects, say up to 30ft. by 10ft., it is still the practice to reciprocate the work upon a table rather than traverse the tool; but this raises an important feature in machine tool construction—to determine the limit at which it is more profitable to move the cutter to the work rather than the work to the cutter. Considering the question of space alone, the former requires for an object 30ft. long, a shop length of at least 60ft., whereas by the latter it would be accomplished within a length of about 36ft., an important consideration. Considering the question of the weight of the object, it would certainly seem more natural to manipulate the tool rather than the work. This has been, to some extent, adopted, particularly in those immense side planing machines, where objects of any size may rest upon a foundation plate, and have the sides planed 10ft. or 12ft. high, by a tool traversing either longitudinally or vertically. In the most modern planing, the various motions of the tool are so arranged as to plane every side except one (that upon which it rests on the table) of a complete cube, and these perfectly true with each other, and also at one setting. Machines adapted for cutting in both directions were introduced by Whitworth many years ago, in the well known "Jim Crow" tool box, and in recent

*Abstract of Presidential Address to the Manchester Association of Engineers, given by Mr. Samuel Dixon, M.Inst.M.E., 14th January, 1888.

Digitized by Google

years an attempt has been made to revive the practice of cutting in both directions; but so far, except on special objects, without very encouraging results. Some of the lines upon which it is probable the future planing machine will be developed might be indicated; but as its very existence is menaced by the advancing milling machine, it would not be profitable. The next group of machines are the boring machines, a very considerable family, even without considering the special varieties. The process of boring is one of great antiquity, and was first employed for cannons, the method of fixing the cutters in a revolving head being not very widely different from the practice of to-day; but accurate boring does not go beyond Watts' day. The method of procedure for such objects as cylinders differs somewhat in practice, but in most cases it is by a boring head carrying the cutter traversing on a stout bar. The most modern practice seems to be to take a heavy, roughing cut through the hole, and then finish by a light cut having a traverse of some $\frac{3}{32}$in. to $\frac{1}{16}$in. per revolution, thus avoiding the wear of the tool, which, of course, tends to make the hole conical. The boring of large objects is one giving rise to many special forms of machines adapted for particular purposes; but the general tendency of all modern work among large objects is to machine as many parts as possible at a single setting, thereby insuring greater accuracy, and the saving of the time required to transport the object and re-set it upon another machine. Take the case of the Corliss engine cylinder. Not only must the machine be capable of boring and facing up the main cylinder, but it must also be able to bore at the same time two of the transverse holes for the circular valves, to face or mill their flanges, drill and tap all the stud holes, insert all the gland studs and cut them off to a given length, and with every operation within the control of a single workman. The slotting machine invented by Roberts about the year 1820 remains much the same in general form to-day as when it left his hands, though it has now grown to enormous proportions. This machine, together with its sister, the shaping machine, invented by Nasmyth, have been very greatly improved in detail, which tends to eliminate their points of weakness, and to give them greater solidity and capacity for heavy cutting without vibration. Drilling machines have advanced in solidity and accuracy of construction, which has been aided by the introduction of the twist drills, now very systematically produced in America and England. As these enable much heavier cuts to be taken, it has been necessary to largely increase the strength of the machines, both to drive these drills and also to resist the increased strains brought upon them. Among the more universal drilling machines, such as the radial machine, modern practice demands that not only shall holes be drilled, but where necessary shall be instantly tapped by the machine, so as to insure perfect accuracy, and dispense with the tedious and imperfect practice of tapping holes by hand. An excellent method of doing this is by having two spindles upon the same saddle, running at different but relative speeds, so that instantly the hole is drilled the second spindle, by a single movement, can be brought over the exact centre of the hole, and the hole tapped any desired depth. This can be done without stopping or reversing the machine, and without altering a single belt. The next group is that of lathes, which are probably a high development of the potter's wheel. The first step from the potter's wheel to that of turning an object between two centres was a very great one, and came about gradually, it being hardly likely that anyone could reason it out. With the introduction of the slide rest by Maudsley and the extension of these principles to the slide lathe by Clement a great advance was made, which was steadily continued for many years; but during recent years there have been vast strides made, necessitated mainly by the increased magnitude of the work to be accomplished, and also by the increased competition. The chief direction has been in the multiplication of cutting tools, for a workman cannot now be permitted to gaze vacantly at the slow advance of a single tool. The number permitted on any lathe for general work should never be less than two, in shafting lathes three tools, in a lathe for heavy forgings four to eight, in pulley lathes four to six, and in fly wheel and rope pulley lathes from eight to sixteen tools should cut at the same time. Our steel works for producing heavy forgings now require the construction of enormously powerful lathes with four, six, or eight tools, each capable of taking a cut 1$\frac{1}{2}$in. deep by $\frac{1}{4}$in. thick, or capable of cutting off something like 5cwt. of steel per tool per hour. With constructions steadily increasing in size, the consideration of how to turn the heavier pieces has led in many works to the great neglect of the cost of producing the small pieces, such as studs, pins, screws, &c., and as these form a most important part of all mechanism, they are a fine test of the efficiency of any workshop. If the time taken to produce a small stud or screw in any workshop is noted, the general tone of the establishment can be easily arrived at. There is nothing so trying as some of the smaller screws, it being frequently found that the screwing appliances are either very primitive or very badly kept. Formerly it was the practice to forge, centre, and turn every stud, pin, and screw between centres; about the most costly process that could be devised. To-day, in the best workshops, this is almost entirely dispensed with, the innumerable host of studs, pins, screws, &c., being turned direct from the solid bar, the cost being but a small fraction of the original process, and the quality of the work produced much superior. It is not merely in small diameters where it is advantageous, but it is often economical for diameters so large as 4in. In such lathes, instead of a single tool, a series of five or six tools arranged in a capstan or circular rest are used, each adapted in form to the several operations, and so arranged that any one can be brought into operation instantly. This species of lathe is one of the most valuable improvements of recent years. A lathe of this type for use where a great number of small screws are made, has been still further developed by being rendered entirely automatic, so that in establishments for the manufacture of screws in great quantities, these machines need only the bar to be put in, and all the operations of advancing the bar, turning, facing, heading, pointing, screwing, and cutting off the stud, are performed quite automatically. The most beautiful example of this was one adapted for watch screws, at the Inventions Exhibition, where the screw was completely turned, and cut off from the wire, and then passed over and presented to a saw and the head nicked—all being automatically done. A comparatively recent development of the lathe has been for the purpose of making articles in duplicate. Modern methods requiring greater system and interchangeability of parts, has necessitated the perfect control of the tools of the lathe in their movements, both as to diameter, and also as to the length turned. The next group is milling machines, the most modern of all, and well worthy of the great attention paid to them by engineers. So far as extended practical use is concerned, they are modern, but by no means modern considered as a process of cutting metals. This process of cutting metals by means of revolving circular steel cutters, having a number of cutting edges, was used to some considerable extent by Clement about 1830 for grooving taps, &c., by fixing a revolving cutter to the slide rest of a lathe. It was here probably where Nasmyth and Whitworth first became acquainted with the system. The simplest form of milling is that of a number of separate tools fixed in a revolving head so that the ends project and form cutting edges. This is a kind of cutter which is largely used, having a diameter of several feet, for many purposes of rough cutting, such as squaring up parts of girders, cranks, &c. The great step in milling was the introduction of the emery wheel for the purpose of sharpening the cutters, and being in considerable doubt as to whether the emery wheel was first made in this country or introduced from America, the author made careful inquiries, and found it was the invention of the late Mr. George Hannay, of Ulverston, brother of Mr. Hannay, of the firm of Schneider & Hannay, the original founders of the Barrow Steel Works. The introduction of the emery wheel, and speedy invention of numerous highly ingenious ways of using it, supplied the great and long felt want for sharpening the circular cutters without softening them. Another step of smaller moment was the introduction of spiral cutters, tending towards increased finish of work. One of the great advantages of using circular cutters as against the single pointed tool is the increased cutting speed at which they can be used. In an ordinary sized cutter there is ordinarily thirty to forty teeth, and as each cutting edge is therefore in operation but about one-tenth of a revolution, and cooling down the remainder of the revolution, it may be run for this short period at a considerably increased speed. The highest cutting speed for wrought iron, with a tool continuously employed, is known to be 20ft. to 30ft. per minute; but when milling a cutting speed of 60ft. to 80ft. per minute can be employed, and the saving of time by using the milling cutter is from 20 to 50 per cent. Many persons consider these milling cutters very fragile; but it is curious to note that the snipping and fracture does not occur when actually cutting, but when running the work against the cutters before the self acting feed motion is put on. This suggests a remedy, which is, never to allow the workman to run the work up against the cutter by hand, or until he can feel it, but to stop, say a short distance from it, and set it in the self acting feed. There is no group of machines which so thoroughly test their own sound construction as do milling machines, for unless the greatest solidity, together with the highest accuracy of construction, be employed, they are practically worthless. When well constructed they promise to become one of the most capable tools of the constructive engineer, for not only is the work produced in greater quantity, but it is also more perfect, and requires little or no further finishing at the hands of the workman. In addition to the ordinary forms of straight lines and circles of which constructions are usually made up, this process of cutting metal lends itself very advantageously to the machining of irregular forms, or profiling, as it is called. Probably the finest specimen of machine work the author had seen was a connecting rod, with its straps, steps, cottar holes, cottars, and everything complete, which had been finished entirely by machinery, and had never been touched with the file. This was done by a foreign firm, but it was quite exceptional. A list of the special machines for locomotives with which the author was acquainted comprised at least forty-five distinct tools specially dedicated to the construction of locomotives, without considering the machines employed in producing the numerous fittings, such as injectors, &c., and of those ordinarily used for repairs. Formerly the thread of a screw bolt was formed by its being made to revolve between a set of dies, which were so horribly designed that the thread was more pressed upon the bolt than cut out, and the bolt had to be traversed backwards and forwards several times before anything approaching to a complete thread could be obtained; to-day, after a thorough study of all the special features entering into the process of screwing a bolt, it is possible to produce a most perfect thread to a standard diameter, pitch, &c., at a single passage of the bolt through the dies, even in bolts up to 3in. or 4in. diam., and without the slightest necessity to stop or reverse the machine. Among small bolts, say $\frac{3}{4}$in. diam., but twenty years ago a production of something like half a gross per hour would have been considered good work, and these would have had but indifferent threads; but to-day as many as six gross per hour can be produced with perfect threads. Apart from the numerous machines used in forging the nuts, &c., there is an extremely interesting series of machines for producing bright nuts, and just as it was in former years regarded a masterpiece of handicraft to produce a perfect bright hexagonal nut by hand, so it is to-day a by no means contemptible performance to produce one of these same nuts rapidly by a series of special machines.

After remarking that there were several special branches in which there was a great call for special tools, the author said that the advance in the making of boilers was very remarkable, and was necessitated by the high pressures now demanded. Another important step was the introduction of steel plates, giving as it did the opportunity of obtaining plates of almost any size, so that to-day plate planing machines, adapted for plates up to 30ft. long, and rolls to correspond for bending plates up to 1$\frac{1}{2}$in. thick, are made. In addition to the many special machines adapted to particular types of boilers, such for instance as the flanging and the turning and drilling of the Adamson flues, the Galloway tube, &c., there are numerous machines adapted for various types of boilers. Formerly, with iron plates and low pressure, the punching of the rivet holes was considered quite sufficient; but to-day, with high pressure and steel plates, the boiler maker cannot afford to run the risk of damaging a steel plate by punching, and his reputation by the consequences which would arise from a flaw escaping undetected. When the demand was first made for having all rivet holes drilled after the plates were in position it was considered to be an enormous increase upon the cost of a boiler, and doubtless the primitive appliances then available for drilling the shells, flues, &c., were highly suggestive of such a result. With the demand has been a rapid development of special machines for this purpose, commencing with the simple radial arm drill, then the two-headed horizontal drill of independent action with the boiler shell suspended from the crane. This machine necessitated the marking out of the plates. The next step was with three horizontal drills around a circular table, upon which the shells were mounted and divided circumferentially by mechanical means. This machine was improved considerably in detail and gave good results; but the latest improvement is a machine in which six drills, all under the control of one man from a single position, are in operation either upon the circular or longitudinal seams, so that now the cost of drilling a boiler is no more than that of one with punched holes. In summarising a few of the leading features of what may be considered as the modern machine tools, accuracy of construction takes the first rank, and this refers not only to the accuracy of a new machine, but to all those costly though highly essential adjustments for retaining its original accuracy during its lifetime. The machine must be accurate in itself, and also be capable of producing thoroughly accurate work by the exercise of moderate skill on the part of the workman, for well known impediments have rendered it desirable to rely as little as possible on the highly skilled workman. Solidity of construction is also essential, giving vastly increased capacity of production, the competition of to-day demanding the accomplishment of any given work in the least possible time. It should be noted how important it is in metal cutting machines that all parts should not only be able to resist breaking strain, but that they should be sufficiently massive to resist vibration, as the effect of every vibration is plainly seen upon the work. The effect of vibration is also felt in the durability of the cutting edge of a tool, for, where both the work and the tool can be held with an unflinching tenacity, the durability of the cutting edge will be very greatly increased. The rapid wear of a tool is often brought about by the snipping of the edges from the vibration in the first instance, rapid deterioration setting in immediately afterwards. The development of appliances for the rapid changing and accurate setting of work is also essential, and can be shown to be so by examining the machine tools of any large workshop, and noting down on one side the machines actually at work, and on the other side those not actually cutting, but stopped for adjusting, setting, or changing work. The proportion will vary with different classes of machines; but it is surprising to find how many are stopped from one cause or another. Here is one of the points where the construction of specialties in quantity gives an advantage, for where the work is in sufficient quantity special appliances are quickly contrived not only for insuring accuracy, but for the rapid changing and setting of work. A further essential feature is the adaptation of almost all machine tools to the particular requirements of each workshop. This has been brought about by machine tool construction having become a highly special branch of engineering, to which many engineers have exclusively devoted themselves, and which permits such experienced men from an inspection of any piece of work to say almost instantly what is the best method of proceeding, and from their special knowledge of the adaptability or combination of the wide families of machine tools, to effect quickly any desired modification to suit a particular work. Tools play such an important part in the world that the intellectual standard of a nation may be judged by the tools it uses, and in like manner the productive capacity of any firm can be fairly estimated by an inspection of the machines and tools employed. Reference was then made to the question of foreign trade, and it was pointed out that it was necessary to include delivery to the customers' works in quoting prices. It was not the author's opinion that any return to protection was advisable, and in his opinion the great thing is to improve our pace, by increased economy in our production, by the improvement of our business capacities for dealing with foreigners, and by the continual exercise of that fertility of mind in invention which has earned for Englishmen the respect of the world, and which causes foreigners often to exclaim that an Englishman is always practical. In addition to the technical training of the workman, he should be supplied with sound geographical and commercial knowledge, so that he might be fully acquainted with the true nature of the competition which threatens him all over the world. The high duties of some countries are not always against England, as often the competition is among three or four nationalities apart from the internal competition. In Italy, for instance, the English engineers have to compete with Swiss, German, French, Belgian, and sometimes Austrian firms; but the heavy duties are levied on each alike. Without questioning the higher average ability of Englishmen, the hours of labour and the rate per hour at which labour can be purchased abroad cannot be ignored. One remaining point of considerable importance is, that many of the oldest engineering concerns in this country are heavily burdened with antiquated machinery. Many of them have grown up in those good old times, when the question was simply, "Can you do it?" and not in these competitive times, when the question is, "How much can you do it for?" A notable feature in good machine tools is that they do not so much wear out as become antiquated; hence in some workshops machines are in use of which the owners are very proud, but which years ago should have been superseded by others capable of doing at least twice the amount of work. They are retained simply because they are capable of doing a certain work, which is all very well if the question of cost be neglected, or it may be, as in the case of limited companies, that they represent a certain sum in the company's stock book. Looking boldly at this question of capital account, the vital consideration in any workshop is the workman. If a workman's wages be put at £80 per year, and considering interest on capital and depreciation on machinery at the rate of 10 per cent., it will be seen that the workman is a sort of animated machine, and the representative of a capital sum of £800, so that the question is not whether a man can profitably occupy a certain machine, but whether the machine can profitably occupy the man.

LOGGING IN CANADA.

II.

(Continued from page 5.)

THE day's work commences at dawn, and ends at nightfall. The log makers proceed, in twos or fours, to their allotted localities. When working in twos, both first fell their tree with hatchets, one man working on each side of the trunk; and, when felled, cross-cut it into the requisite lengths. When four men are working together, which is found as a rule to be the most effective plan, two do the felling and butting, while the others confine themselves to cross-cutting. Practice has rendered these men so proficient in the use of the axe as to keep tree felling machinery out of the field; for, in spite of the fact that steam tree fellers are used on a large scale and to great advantage in many countries, they would hardly show a saving of time in a Canadian pine forest, where many of the trees are of small diameter. As a matter of fact, tree felling machines work to the best advantage on hard wood trees of considerable diameter, say 4ft., 5ft., or 6ft., for under such circumstances they have more work to do at a time, without being shifted; and again, the hardness of the wood does not perceptibly influence the speed at which these machines work, whereas increase in either diameter or hardness of the timber effects a very marked diminution of the output when it is a question of felling by hand.

To give an idea of the rapidity with which pine felling is carried out in Ontario by hand, it may be stated from actual observation that a tree 24in. diam. was felled by two men in 4 minutes 20 seconds. When down, one of the "fellers" marked it into lengths for the cross-cutters, who took three cuts in it in as many minutes, while the above mentioned feller was "bark marking" the lengths for purposes of identification, and his companion was trimming the ragged butt end, which latter operation took 6 minutes 45 seconds. Thus, in the space of a little over 11 minutes, a 24in. standing tree was converted into three finished logs, ready for transport. It is probable that this is somewhat above the average rate of working, as these men saw they were being timed, and were consequently on their mettle; but, in any case, it is interesting to know that such a point of efficiency can be reached. A gang working at Bissett's Creek, on the Ottawa river, in which there were eight log makers all told, and which was visited by the writer on the 20th March, 1886, had, from the 1st October of the previous year until that date, "made" 20,496 logs of good timber, the average measurement being 17½in. diam. This represents an average of seventeen logs a day to each man, without reckoning in the "culled" or rejected logs, which are necessarily numerous.

It is important in felling the trees to see that the trunks fall clear of all obstacles, and in such a position as will allow of their being removed with comparatively little difficulty. This is no easy matter in thick forests; but it is regulated with considerable skill by these men, who, by the manner in which they notch the trunks, seem to be able to make them fall in any desired direction. In fact, an experienced woodman will have no difficulty in indicating beforehand the exact position which his tree will take when felled. While the log makers are at work as above described, another set of men are employed in cutting the necessary roads for the passage of the timber. The first road to be cut is that which leads down to the river, branching off from which are the numerous side tracks, which terminate at the various spots where the woodmen are at work. It is usual to construct the main road of a sufficient width to allow of two sleighs passing each other, whereas the side tracks are as a rule only just the necessary width for the passage of one sleigh at a time. When the road makers have completed a track up to a site where felling is going on, "roll-ways" are constructed on the side of the road at suitable distances from each other. A "roll-way" is a frame work of logs, made up to about the height of the floor line of a sleigh, with an incline leading up to it, and is used for the purpose of raising the logs to a convenient height for loading them on to the sleigh. When trimmed (as in Fig. 2), the logs are ready to be dragged to the roll-ways on the first step of their long journey. For this purpose they are handled in much the same manner as is usual in most other countries, being turned and adjusted by means of the ordinary cant hook and crowbar, until the skidding tongs (A, Fig. 3) can be fixed, or a chain can be placed round one end of them, when they are hauled through the intervening bush by a team of two horses to the nearest roll-way, on to which they are placed ready for the sleighs. A useful appliance for shifting the position of the logs by hand is the pair of lug hooks shown at B, Fig. 3. It is not usual to fell trees of a smaller diameter than 12in., and it is understood that the lessee of the timber "limit" is to take every reasonable precaution not to injure any young growing timber thus left behind. It is also greatly to his own interest not to fell more timber than can be got on to the river before the thaw, since it would be waste of labour for which he would have to pay. Logs remaining in the forest until the following season become often so worm-eaten and otherwise injured as to be not worth transporting. To regulate the log making to suit the capacity of the transport requires a certain amount of judgment, as will easily be seen when it is borne in mind that some of these timber "limits" extend over hundreds of square miles.

Before the logs leave the forest they have to undergo the careful scrutiny of the "culler," who, with the aid of the ordinary "Scribner's scale," registers the contents of each log in his book, marking the unsound, as already mentioned, with a "cull." The number of culled logs is also

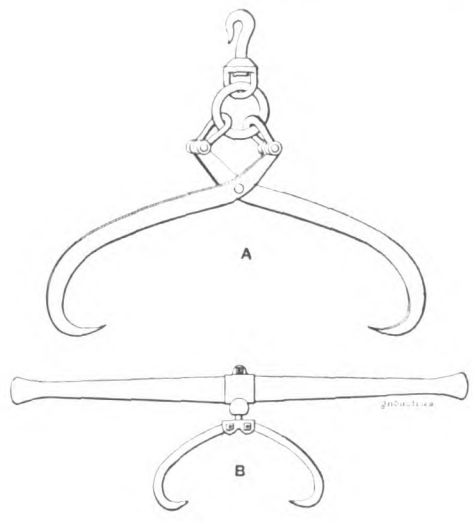

FIG. 3.

carefully noted, and though they are not measured individually, an average is struck which is considered sufficiently accurate for the assessment of Government dues, which have to be paid on culled as well as on good timber.

An interesting and ingenious system of handling timber by mechanical means in the forest has recently found a footing, more especially in the United States, on account of the fact that railways are greatly taking the place of water ways for the transport of logs in that country. This system, if not dependent on the presence of a railway, at all events lends itself better to being worked in localities where a line of rails can be laid down. The inventor, Mr. Butters, of Michigan, calls it a "steam skidding and loading machine," and as that somewhat comprehensive title describes the operations it is destined to perform, and the engraving (Fig. 4) shows very clearly the way the apparatus is fixed, a brief description of the *modus operandi* is all that is necessary. A special form of winding or "skidding" engine is first of all run into the centre of the tract of forest to be cleared. If a line of rails can be laid down to the spot where the engine is to be eventually fixed, it will facilitate its being placed in position, and will also furnish a rapid means of

LOGGING IN CANADA.

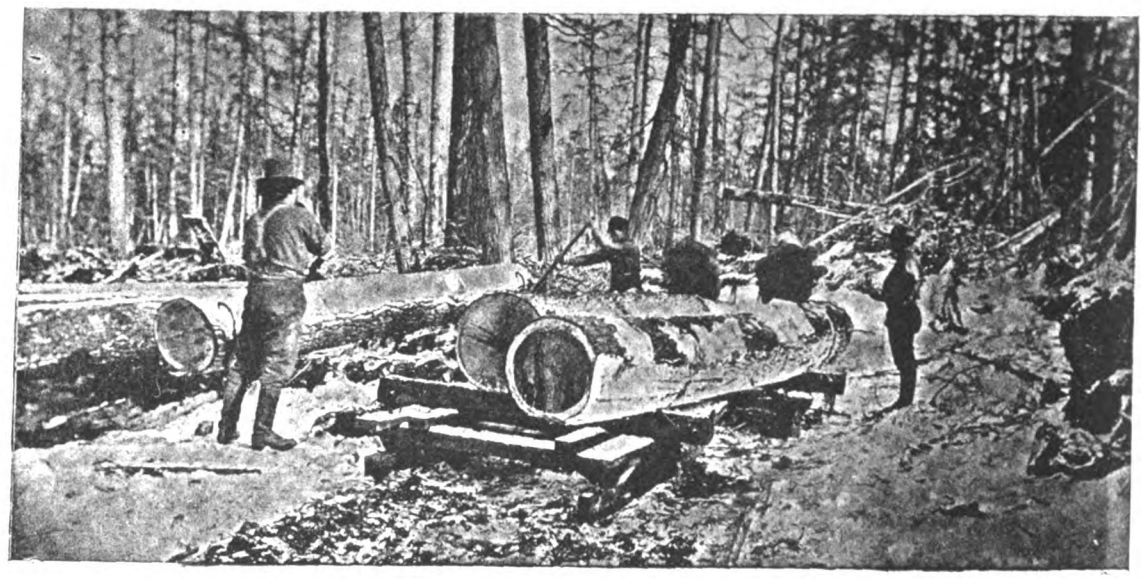

FIG. 2.—HANDLING LOGS IN THE FOREST.

dispatching the logs on their way. If, however, there are no rails, this system can be worked in any place to which it is possible to bring the skidding engine, as the machine can of course load sleighs as easily as railway trucks. The skidding engine is fixed close alongside the railway track, or sleigh road, as the case may be, and a strong tree is left standing on each side of the road, as shown in the illustration. Between these trees is stretched a wire rope of sufficient strength to bear the weight of the heaviest log to be lifted. On this rope, at a point immediately above the conveyance to be loaded, a pulley block is hung, through which passes the rope for lifting the logs. To one end of this rope are attached the dogs for holding the timber, and the other end is passed through a second pulley fixed to the tree nearest the engine, and thence round one of the winding drums of the engine itself, so that the log can be raised and lowered as required. The lifting block is kept in position by two steadying ropes, one from each tree. As regards the "skidding," which may be taken to mean, in this instance, collecting and hauling, this is carried out by the same engine in much the same manner as the loading, only that, instead of a stationary block, a travelling block is required, and as it must move both ways, it is worked by two drums instead of one, from the engine, one drawing it with the log towards the place for loading, and the other taking the empty line back into the forest. The block travels along a wire rope between one of the trees near the engine, and another at as great a distance off it as practicable, collecting all the logs within reach. After clearing one district of the felled timber, the rope is detached from the tree and made fast to another, which has been left standing at a suitable spot in another district, at a similar distance from the centre tree. Thus an area of considerable size can be cleared without moving the loading engine, the delivery line representing the radius of the circle to be cleared, the direction of which can be changed as required on the circumference, but bringing the logs always to one centre for loading. It is claimed for this apparatus that it can be fixed ready for work in from two to three hours. The economy effected by this apparatus over hand labour must necessarily depend on local circumstances, such as the positions of the trees, and the facilities for getting the engine to the required place; but when at work, and manipulated by half a dozen labourers, it is meant to take the place of the men and horses above mentioned, who haul the logs through the forest to the "roll-ways," and also those who stack the logs on the "roll-ways" and load the sleighs.

(To be continued.)

THE COST OF PRODUCING COAL IN BELGIUM.

IN the course of an American consular report on the mining industry of the Liège district, some interesting figures are given, showing the cost per ton of producing coal between 1882 and 1886. In 1882 the cost amounted to 1·24fr. per ton, which increased slightly in the following year, when it was 1·34fr. Since that date a steady diminution has taken place, the cost being 0·96fr. in 1884, 0·85fr. in 1885, and 0·62fr. in 1886.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 17TH JANUARY, 1888.

THE IRON MARKET.—There is still hesitation on the part of Parisian consumers, who, being sufficiently provided for present needs, prefer to wait till the course of events has become more clearly discernible, so that the markets remain quiet. But these conditions are limited to Paris. Throughout the country, consumers exhibit a growing eagerness to buy. From all the centres of the iron industry an active and increasing demand is reported. The markets in some parts, notably in the North, are animated, and prices are very buoyant. There is no change to note in the base prices, but in most transactions for forward delivery these are slightly exceeded. For the second quarter, manufacturers require a considerable advance on the present base prices. Judging from the steady current of business now flowing, trade is rapidly recovering. The tone of affairs generally is hopeful, and the prospects of the near future encouraging.

RESULTS OF THE BREWERS' EXHIBITION.—For once everybody seems satisfied with the results of the Brewers' Exhibition recently held in the Palais de l'Industrie. M. Prévet, in a report addressed to the Minister of Agriculture, says that the ends in view in forming this Exhibition, which were in the first place to make French beer better known and appreciated, and in the second place to bring to the notice of brewers the best processes and apparatus, have been fully attained. The Exhibition has, he adds, given immediate results. Public opinion has been turned in favour of the home made product, which change shows itself in greatly increased orders to the exhibitors. The results have been, according to M. Prévet, equally beneficial to the makers of machinery and apparatus for brewing. The exhibits have shown, he says, that the national industry has nothing to fear from foreign rivals. M. Prévet concludes with a recommendation to establish in France a Brewers' Laboratory and School of Brewing similar to those already existing at Munich and Copenhagen.

THE FOREIGN TRADE IN BEER.—France is becoming more and more a beer producing country. A great advance has been made in this direction in the course of the last five years especially. There has been a steady increase in the consumption of beer throughout the last decade, but since 1884, when the imports reached their highest value, there has been a rapid decline in the quantities of beer purchased abroad. The diminution has taken place chiefly in the trade with Germany, and may be due in part to political antipathies; but other countries, except England, have also suffered. At the same time the exports of French beer have constantly increased. The value of the beer imports in the first eleven months of the year, which amounted to £711,720 in 1884, dropped to £670,760 in 1885, to £592,440 in 1886, and to £447,880 in 1887. The exports increased in value from £52,680 in 1885 to £57,200 in 1886, and to £59,820 in 1887. The imports of foreign beer into France in the first eleven months of 1887 amounted to 4,786,628 gallons. Of this quantity 3,819,552 gallons entered from Germany, 396,000 gallons from England, 42,240 gallons from Austria, and 528,836 gallons from other countries.

THE TRAMOND-LEBEL RIFLE.—The following are some of the distinctive features of the Tramond-Lebel rifle, which the Government small arms factories are turning out with all possible speed: The calibre is only 8mm. With this small bore and a suitable bullet a very low trajectory is obtained. The bullet, of unusual length and weighing 15grm., has a muzzle velocity of 1800ft. per second. To enable it to withstand without serious deformation the enormous pressure exerted upon it, the metal used is lead hardened with antimony, and this is coated with German silver to give it greater resisting power. The result is marvellous accuracy in shooting. There is some talk of a smokeless powder, the invention of M. Vieille, the Government explosives engineer, to be used with this arm. For present use, however, a modified form of the ordinary gunpowder is being manufactured.

PRIZE FOR ELECTRIC LIGHT INSTALLATION.—Among the subjects for which the Société Industrielle of Amiens has offered a prize, is "the best electric light installation in an industrial works." The light must have been in operation for at least a year, and it must be proved to be cheaper than gas made on the premises. Further, the installation must be equivalent to a gas system of not fewer than three hundred jets. Detailed plans and descriptions must be sent in before the 30th April next.

BERLIN, 16TH JANUARY, 1888.

THE COAL MARKET.—An important change in the condition of the German coal market is imminent, since the period for which the colliery union was established is drawing to a close. A meeting of the representatives of Upper Silesian coal mine owners was held in Kattowitz a few days ago to consider the formation of a union to regulate the total output of the district, and to endeavour to form a sales bureau similar to that of the rolling mills. Should this convention be formed, it will almost completely rule the prices of coal, the only difficulty in the way being the importation of foreign coal, which is admitted duty free. The exports of Westphalian coal and coke from Hamburg amounted to 549,460 tons in 1887, against 518,930 tons in 1886, and 536,510 tons in 1885. The imports of English coal during the same periods were 1,230,000 tons, 1,210,000 tons, and 1,138,700 tons, respectively. These imports are likely to considerably increase if the coal owners in Upper Silesia should attempt to artificially raise prices.

THE IRON MARKET.—Now that the influence of the holidays has finally subsided and business has returned to its normal channels, it is possible to form an estimate of the probable course of trade in the near future. On all hands it is expected that the output of the Upper Silesian blast furnaces will, during the present quarter, fall rather short of the requirements, notwithstanding the fact that the export trade to Russia, which last year amounted to about 15 per cent. of the total production in the district, has been entirely stopped. The great activity in all branches of the finished iron trade has increased the demand for crude iron to such an extent that the whole production can now be placed in the home market. At the present moment there are twenty-eight furnaces in activity, producing the same quantity as thirty-two furnaces eight years ago, the increase of output per furnace being due partly to improved methods, but principally to the prevailing tendency of working up richer ores. The ores at present worked up are spathose iron ore, magnetic iron ore, and a very rich purple ore, the greater quantity being imported from Hungary, Poland, and Thuringia, although a fair amount of ore is also raised in Upper Silesia. In this connection it is worth mentioning that the business of producing crude iron has a tendency to be differentiated into branches. Formerly, Silesian mine owners smelted their own ores, but now their tendency is to simply raise ores and sell them to the blast furnace owners. This is obviously more expedient in a trade which is bound to import some of the ores. To give only one instance of this tendency to differentiate production into distinct branches, I might mention that the Henckel iron ore mines have taken the lease of the large ore deposits belonging to the town of Beuthen, in Upper Silesia, and have blown out their own furnaces, thus restricting their business entirely to the production of ore. Owing to the favourable prospects of the market, some of the Upper Silesian works are contemplating extensions, by erecting new rolling plant, new blast furnaces, and in one case, also a plant for the production of open hearth steel, in which specialty the Upper Silesian district is as yet far behind Westphalia.

A SYNDICATE OF WIRE NAIL MAKERS.—The present tendency to syndicate all the trades which admit of such a measure is again exemplified by the proposed syndicate of German wire nail makers. The majority of manufacturers in Upper Silesia and Westphalia have already definitely agreed to join this syndicate; manufacturers in Saxony are favourably disposed to it, and those in Southern Germany propose to form a separate syndicate, but will abide by the prices fixed by the general syndicate. As far as can be gathered at present, the object of the syndicate is not so much to unduly increase prices, but rather to give the trade greater stability. The total annual consumption of wire nails in Germany is estimated at 66,000 tons, whilst 43,000 tons are annually exported. One common sales bureau for the home market is to be established at Berlin, and another for the export trade at Hamm. The necessary steps to finance the undertaking have already been initiated with Berlin banking firms. The turnover in the trade is estimated at slightly over £1,000,000 per annum.

VIENNA, 16TH JANUARY, 1888.

THE COAL MARKET.—Bohemian coal is at present being largely exported to Germany, *via* Bodenbach and Eger, from the Buschtehrader collieries. The price obtained is higher than can be got in the eastern parts of Bohemia, where the Silesian coal competes. This export traffic forms a considerable source of profit to the railways. During the past year the Salgo-Tarjauer Company produced 500,000 tons of coal, or 25,000 tons more than in 1886, at a profit of 9 per cent The Nord-Ungarische Kohlenbergwerks Actiengesellschaft produced 266,200 tons at a profit of 8 per cent.

THE IRON MARKET.—There is no change to be reported in the iron market, as traffic has been hindered by the excessively cold weather which has been experienced since the holidays. The prospects for the year are good, and as a number of large railways, projected some time ago, will probably be built, an increase in the consumption of iron is likely to follow. It also appears that the building trade will be busy this year, and that large orders will be received for girders. Orders have been given by our sugar factories for new machinery, and some fresh work in the way of locomotives and waggons will assist engineering shops through the quiet season. The annual report of Messrs. Ganz & Co., one of whose specialties is chilled railway wheels, states that the past year's business was fairly satisfactory; twenty-three turbines were installed by the firm during the year. The Schlick'sche Foundry executed some important orders for bridge work, but owing to low prices and foreign competition, only a small dividend is declared. The Rinia-Murany-Salgo-Tarpauer Iron Works declare a dividend of 6 per cent. on the last business year, and pay 3 per cent. to the reserve and depreciation funds.

ELECTRIC LIGHTING.—The Vienna Society of Electricians appointed some time ago a committee to draw up rules and regulations for the public supply of electricity, which will be submitted to Parliament with a view to obtain a kind of Electric Lighting Act for Austria. The committee have finished their labours, and their report will be laid before the members at the next general meeting of the Society. It will then be discussed, and, if necessary, amended, after which the Society will finally adopt and recommend it as the basis of a Bill to be introduced in the next session of Parliament.—Messrs. Czeija & Nissl, of this town, have just brought out a new search light, which has been specially designed for use on torpedo boats. The lamp is self feeding and works perfectly well, not only when placed vertically, but even when inclined to an angle of 65° from the vertical. —The Allgemeine Elektrizitäts Gesellschaft, of Berlin, is now establishing a branch at Vienna. The company has commenced negotiations with the Imperial Continental Gas Association, with a view to taking over their electric light works in the Schenkenstrasse, and the installation at the Vienna Opera House. This company will also be represented at the forthcoming Exhibition in the Prater by an installation of 90 arcs and 1500 glow lamps, lighting the park to the west of the Rotunda, and a portion of the interior of the latter. The rest of the lighting will be divided between the following firms: Siemens & Halske, of Vienna, Egger & Co., Kremendky, Mayer, & Co., Krizik, Ganz, & Co., and Brueckner, Ross, & Co., who will install an aggregate of 180 arcs and 2000 glow lamps. As in 1883, a special feature of the Exhibition will be model rooms furnished in various styles, and lighted by glow lamps, for which purpose about 750 lamps will be required. In the Emperor's pavilion there will be 100 glow lamps. Generally speaking the electric light will be installed not as an exhibit, but with a view to produce the best illumination of the other exhibits. The total motive power required is estimated at 600 h.p. There will be telephonic communication by means of Fostin-Herrman underground cables between the Vienna Opera and the Rotunda.

MILEAGE TICKET BOOKS.—The administration of the Austrian State railways has just introduced, for the convenience of commercial travellers, a system of paying for tickets which has already been tried with good results on some of the American railways. This system consists in the issue of mileage ticket books available for one year, and containing coupons to the aggregate value of 150fl., but costing only 123fl. The coupons are of different value, viz., of 5kr., 10kr., 1fl., and 5fl., and upon handing in at the booking office such a number of these coupons as will make up the right fare, an ordinary passenger ticket for any distance, and available by any train, is issued. If all the coupons are used before the expiration of the year, a second mileage book of the value of 30fl. can be bought by the original holder. To prevent the use of these tickets by others, the mileage book, which contains the photograph of the owner, must be presented when asked for by the officials; but the owner is permitted to pay with coupons for the tickets of persons who accompany him.

BRUSSELS, 17TH JANUARY, 1888.

THE COAL MARKET.—There is plenty of business being done, and the market is firm. Nuts are quoted at from 12s. 7d. to 15s. 2d.; unscreened household coal at 8s. 5d. to 9s. 7d.; small coal at 4s. 5d. to 6s.; and coke at 11s. 2d. The situation remains good, especially for coal for industrial purposes, with the exception of hearth coal. Owing to the scarcity of coal for metallurgical purposes, prices show an improvement, and business in this branch would be better still were it not for the traffic on the canals being stopped. The rates for household coal for the home market have been maintained, but the same has not been the case with the exports, though the volume of business is increasing. In France, which is our principal export market, the collieries of the Nord and Pas de Calais used to turn out only small quantities, which were sold at rates of about 2s. 6d. to 3s. dearer than Belgian coal; but now the output has been largely increased, and the price is nearly as low as that of our own coal. Sales of Belgian coal have been made in Paris at 1s. 3d. per ton less than last year, owing to the low offers from French collieries.

THE METAL MARKET.—At present attention is mainly being directed to the prices of coke and pig iron. Coke has risen to such an extent that the cost of producing pig has considerably increased, with the result that it has to be sold at higher rates, while at the same time finished iron has proportionately advanced. This is causing great difficulties, the only solution to which at present would be a rise in finished iron, but the demand is not sufficiently large to warrant this. There has been some increase in the orders for finished iron, especially for Italy, in consequence of speculative purchases. Generally speaking, however, there are not many orders for delivery after the first quarter of this year, and though many makers have more work in hand than they can well manage, they expect to have to restrict their production by April. Those rolling mills which have blast furnaces of their own are in a better position than the others, as, being to a certain extent independent, they were able to engage themselves further ahead at the time when orders were pouring in; the Cockerill, Sclessin, l'Espérance, and Grevignée works are in this favourable position, and several of them have also collieries of their own. The Ougrée iron works, which turn out specialties, are also well employed. Locomotive builders have very little to do, and it is expected that several works will have to close; it would be well if the State railways would take this opportunity of ordering new locomotives and rolling stock, of which they are much in need. The last contract for two

Digitized by Google

lots of ten carriages each was given to Nicaise & Delaeve at £1831. 12s. for each lot; the Franco-Belgian Company and Sineffe both quoted £1832.

Flax and Yarn Markets.—Business in home grown flax has further decreased. Prices have now a marked downward tendency. No serious drop is apprehended; but, on the contrary, it is generally believed that a small reduction will bring prices to their true level, and thereby give occasion to a steady course of business. At Courtrai the market is dull and heavy. At Bruges the demand is less, and prices are giving way. At Ghent the conditions are somewhat different; the market is well supplied with home grown flax, and all on offer finds ready purchasers at prices that tend in favour of sellers. A large amount of business has been transacted in Russian flax, which maintains its price. The situation has slightly improved for linen yarns; a better demand has sprung up, which, in the present condition of affairs, seems likely to continue and to increase. The high prices of cotton yarns deter buyers from dealing beyond the needs of the moment in that class of goods.

Society of Engineers and Manufacturers.—This Society has been in the habit of organising every year in the Palais de la Bourse special scientific and industrial exhibitions. During 1888 the following Exhibitions will be held under their auspices: (1) Engineering tools and instruments; (2) processes, materials and products for the reproduction, enlargement, and reduction of plans and drawings; (3) plans and models of workmen's dwellings, and constructive details in connection with the improvement of the same. The first two Exhibitions will be international. The Engineering Tools Exhibition will be opened on the 3rd proximo, and will continue for about a month. No charge is made for space, the only expense being the cost of installation, which, as a rule, will not be over £1. Communications should be sent to M. le Président du Seconde Comité de la Société Belge des Ingenieurs et Industriels, Palais de la Bourse, Brussels.

DÜSSELDORF, 16th January, 1888.

The Iron Market.—Business has resumed its accustomed course, and the iron market has again become animated; but the prospect is not wholly cloudless. The feeling of uneasiness occasioned by the recent advance in pig iron, which I reported last week, has not abated. Manufacturers are beginning to perceive the true bearing of the situation on the export trade. They contend, and the contention admits of easy proof, that in the present state of the foreign trade they cannot compete in neutral markets so long as they have to pay the rates now current for their raw material. Meanwhile, however, buying goes on apace for delivery in the second quarter of the year. Forge, hematite, and basic pig are the classes chiefly in request. The demand is still in excess of production, though the latter is being pushed to the utmost. Stocks at the blast furnaces now scarcely exceed 30,000 tons of all sorts, except foundry pig; the latter amounts to about 20,000 tons. The imports of English pig in the month of December were very heavy. The Board of Trade returns show that the direct exports of pig iron to Germany amounted in that month to 7240 tons, against 3819 tons in the same period of 1886, while the quantity landed in Holland reached 19,479 tons, against 11,333 tons. As evidence of the confidence with which the future is regarded, I may mention the fact that Herr Stumm, of Neunkirchen, has acquired an extensive tract of land on the Upper Mosel, at Ücklingen, in the district of Diedenhofen, for the purpose of erecting a set of blast furnaces in that rich iron-bearing country. The following are the present base prices of the goods enumerated, the figures in parentheses being the prices six months ago: Spiegel pig of 12 per cent. manganese, 52s. (50s.) per ton; Rhenish-Westphalian white forge pig, 50s. (43s. 6d.); basic pig, 45s. (42s.); Luxemburg forge pig, 35s. 2d. (34s. 6d.); Luxemburg foundry pig, No. 3, 41s. (40s.); German foundry pig, No. 1, 57s. (55s.). Common bars, £6. 2s. 6d. (£5. 10s.); common plates, £7 (£6. 15s.); boiler plates, £8 (£7. 5s.); sheets, £7. 11s. (£6. 15s.) a ton.

Copper Prices.—The present abnormal situation of the metal market renders the tenders for the railway contracts received at Cologne on the 10th inst. specially interesting. The offers, which include the cost of delivery at the central works at Nippes, were as follows: For 35 tons of copper rods, eleven tenders, highest offer, £100; lowest, £89; mean, £91. 4s. per ton. For 15 tons of copper sheets, eight tenders, highest, £100; lowest, £89; mean, £92. 2s. For 10cwt. of copper wire, nine tenders, highest, £107. 10s.; lowest, £90; mean, £96. 6s. For 7 tons of copper tubes, six tenders, highest, £105; lowest, £92; mean, £100. 2s. For 20 tons of copper plates for locomotives, there were two tenders of £104 and £103 delivered at Berlin, and one tender of £104. 10s. delivered at Frankfort.

The Sugar Crop.—The heavy falling off in the sugar-beet crop of 1887 is showing itself in the short duration of the campaign, which is already ended for a large proportion of the manufacturers. The drought of August and September occasioned an incomplete development of the roots. According to the latest official estimates, the quantity harvested last year in Germany amounted, in round numbers, to seven million tons, which is 1·3 million less than in 1886. But the yield of saccharine matter has been extraordinarily high, so that the deficiency in quantity has been in part compensated by the quality. Improved culture has year by year improved the beet. To obtain one ton of raw sugar we needed 10·76 tons of roots in 1878, 11·57 tons in 1879, 11·22 tons in 1880, 10·31 tons in 1881, 10·36 tons in 1882, 9·26 tons in 1883, 9·07 tons in 1884, 8·44 tons in 1885, 8·20 tons in 1886, and (apparently) 7·75 tons in 1887. The slight fluctuations observable are due to the influence of the seasons. Thus every acre of land under beet cultivation now yields 1·39 times the quantity of sugar obtained ten years ago. As the duty, calculated on 10·15 tons of roots to the ton of raw sugar, will, this year, amount to only 131·7 marks, instead of 172·5 marks, there will be a bounty of 40·8 marks per ton on all sugar exported.

LILLE, 17th January, 1888.

Textile Manufactures.—We are not yet wholly clear of the season of stock-taking, and as long as the course of business is thereby retarded, the true tendencies of trade cannot be fully discerned; but there are many symptoms of renewed life, and no lack of evidence to strengthen the hopes raised by the state of trade at the close of 1887. Business has been sufficiently animated in the second week of the year to justify the expectation of a larger volume of trade all round after this week, and this gives a healthy tone to the market. A fair amount of business has taken place in linen goods this week. Prices remain low, but there are indications of speedy improvement. The business in raw materials exhibits more buoyancy. Flax is in strong demand, and yarns are moving steadily upward. This rise in yarns must lead to an advance in cloth, and the movement once begun is likely to continue till a more remunerative level is reached. At Roubaix the situation is one of expectation. The time has not arrived for a general revival in the woollen trade, but there is a firm belief that we are on the eve of a period of great activity. A manufacturer writes: "The year 1888 begins in the best possible condition, and we cannot doubt that it will bring us a larger volume of trade in all kinds of woollen goods, and more remunerative prices than we had in 1887." German buyers have dealt largely in combed wool this week at about 5 francs per kilo. A move in the cloth market would bring about general activity.

Flax and Yarn Markets.—There has been another week of animation and firm prices in the market for flax. Home grown is in brisk demand. All the circumstances of the trade point to continued activity in this class of goods. Russian has been less sought after this week, but a large volume of business has nevertheless been transacted, and prices have moved in favour of sellers. A characteristic feature of the yarn market this week is a slight retardation of business accompanied with rising prices. Weavers have bought largely of late, and are therefore sufficiently provided with yarns for some weeks to come, and spinners have work enough in hand to keep them employed till the end of the first quarter. The latter consequently exhibit no eagerness to press sales, and have not hesitated to further advance their rates for the medium and finer numbers, which are the class of yarns most sought after. Jute yarns still command a large business at steadily advancing prices.

The Iron Market.—There is now a steady course of business in iron, free, on the one hand, from distrust and hesitation, and on the other, from unhealthy excitement. Consumers exhibit some eagerness to buy, but cannot be induced to deal in distant "futures" at the higher rates asked by the manufacturers for such bargains. For delivery in the first quarter transactions are effected readily enough. Merchants, however, are contracting on the manufacturers' terms for delivery in April and May, a circumstance significant of a belief on the part of the former that the latter are able to maintain the existing union, and thereby to control the market for some time to come. Clearly the situation is a strong one, and the constantly improving prospect fully justifies the very hopeful tone which now prevails in this locality. Prices are unchanged, but show a tendency to harden in some directions.

MADRID, 16th January, 1888.

The Barcelona Strike.—This strike is gradually being overcome, and masons are daily returning to their work. There is, however, no very good feeling between the contractors and workmen, and it is probable that the former will meet with serious difficulties in carrying out their contract for the exhibition buildings in time. The work is, however, being actively proceeded with in the meantime.

Electric Lighting.—Fourteen petitions have been presented to the municipality of Madrid to use the public thoroughfares for laying cables for the supply of electric light and power; but, in the unbusiness-like manner in which such things are dealt with by our local authority, no decision has been come to, and it is difficult to say when there will be. In the meantime a very badly managed company, who have a provisional authority to lay cables, is supplying about a thousand incandescent lights and some eighty Gramme arcs. On the other hand, the Madrid Gas Company pretend that they alone have the right to lay underground cables for electric light. In fact, everything relating to distribution is in such a state of chaos, that even primary batteries would have a chance of adoption if their working expenses could be brought down to a point at which the cost would be about equal to 8s. per 1000ft. for gas. Isolated installations, with engines of any kind, require a license from the authorities, and might therefore in many cases meet with difficulties.

NEW YORK, 7th January, 1888.

Railways.—There is a scarcity of rolling stock, owing to pressure of goods in transit; but rates are very low. Some of the Western railroads have reduced their rates to such an extent that heavy losses must be the result. The Western railway lines entering Chicago have, after three months' work, completed the installation of a plant of 35 to 50 ton scales at the stock yards. They will in future weigh all live stock, and charge for transport by weight, instead of by the car load. The track of the Chicago, Santa Fé, and California Railroad bridge across the Mississippi at Fort Madison, Iowa, has now been completed, forming a connection between the States of Illinois and Iowa. The extension of the Chateaugay Railroad to Saranac Lake has also been finished. The Martin system of steam heating has been substituted for stoves on the Erie Railway. The Westinghouse brake has been adopted on the New York Central and Hudson River Railroad both for passenger and freight cars.—The Mexican Government has just granted a concession for a railway to commence at Tepic, in the State of Jalisco, running north-west to Mazatlan on the coast, and thence north-west through the State of Sinola, connecting with the Southern Pacific Coast at Yuma, Arizona Territory. The new line, which will be rather circuitous, will tap a very rich mining district, and is expected to be completed in three or four years.—The freight committee of the Trunk Line have adopted a higher scale of rates for iron and steel manufactures, which will come into force next week. During the past year, 12,724 miles of new main line track were added to the railway system of the United States. The number of new lines is 364. Four States and two Territories, viz., Kansas, Nebraska, Texas, Colorado, Dakota, and Montana show together an addition of 6400 miles, or about half the total mileage added. The total cost of the new lines is estimated at £65,000,000. The total railway mileage of the United States at the close of the year was in round numbers 151,000 miles.

Car Heating.—In answer to a circular from the Secretary of the Treasury inviting suggestions from car builders and others as to the best means of constructing and heating cars, so as to prevent loss of life and property, 216 communications were received. Of these twenty-eight proposed to heat the cars by steam from the engine, twelve by hot air from the engine, twenty-three by heat from an independent car, twenty-six to heat and light by means of electricity, thirty-four by means of improved heaters or stoves in the cars, eight suggested specially constructed safety cars, having the heating and lighting done by gas.

The Navy.—The keel blocks for the new 6000-ton armoured cruiser have been laid at the navy yard here, and the buildings are nearly ready for the machine tools. The engines of the cruiser "Chicago" were severely criticised by foreign engineering journals; but, though the machinery was different from that of any war vessels that had been built, its practical success on one of our merchant vessels satisfied the designer that the "Chicago" would fulfil the requirements as to speed and horse power. A trial trip of this vessel was made recently with very successful results. The maximum speed obtained was 16·83 knots, and the mean for the six hours' run was 15·1 knots, making the proper allowance for tides. The boiler rooms are fitted for forced draught; but during this trial it was not used, as the boilers with natural draught furnished all the steam required. The maximum horse power obtained was 5248 i.h.p., and the mean for the entire run was 5084 i.h.p. Both engines worked very well, and did not require slowing down from beginning to end of the trial.

PHILADELPHIA, 7th January, 1888.

Iron and Steel.—Prices have been steadier during the past week, and a considerable business has been done in bar iron. An order for 15,000 tons of steel rails has been placed in Eastern Pennsylvania. Orders for only 200,000 tons of rails for delivery this year have been received so far, but prospects are good for the continuance of last year's railway building "boom." The ship yards along the Delaware, while not working up to their full capacity, seem to have plenty of work on hand. A memorandum issued by Messrs. Cramp, during the late meeting of the American Society of Mechanical Engineers, showed that they had work on hand for seven new ships aggregating 41,000 i.h.p. They have 1500 men employed at present, their total capacity being 2600.

Electric Railways.—The last year has seen a wonderful growth in electric railways. There are now in the United States over 80 miles of road on which the motive power is electricity. Eighteen towns have plants in operation, in lengths varying from 1 to 11 miles. Contracts have been made for roads, and they are now being constructed in seventeen other towns, and there are fifty-nine projected roads. The greater part of the mileage is divided about equally between the Doft and the Van Depoele systems.

Dry Dock.—The necessity of a dry dock at Erie has been felt for many years, and numerous attempts have been made to secure the necessary capital. Now the project seems in a fair way to be realised. The syndicate, which has just purchased the Gogebic ore range, have through an agent secured the ground necessary to build a ship yard and dock. They propose putting on a fleet of fourteen vessels to carry their ore to the lower lake ports, and will begin work as soon as the season opens.

BOILERS OF THE GUNBOAT "CERAM."

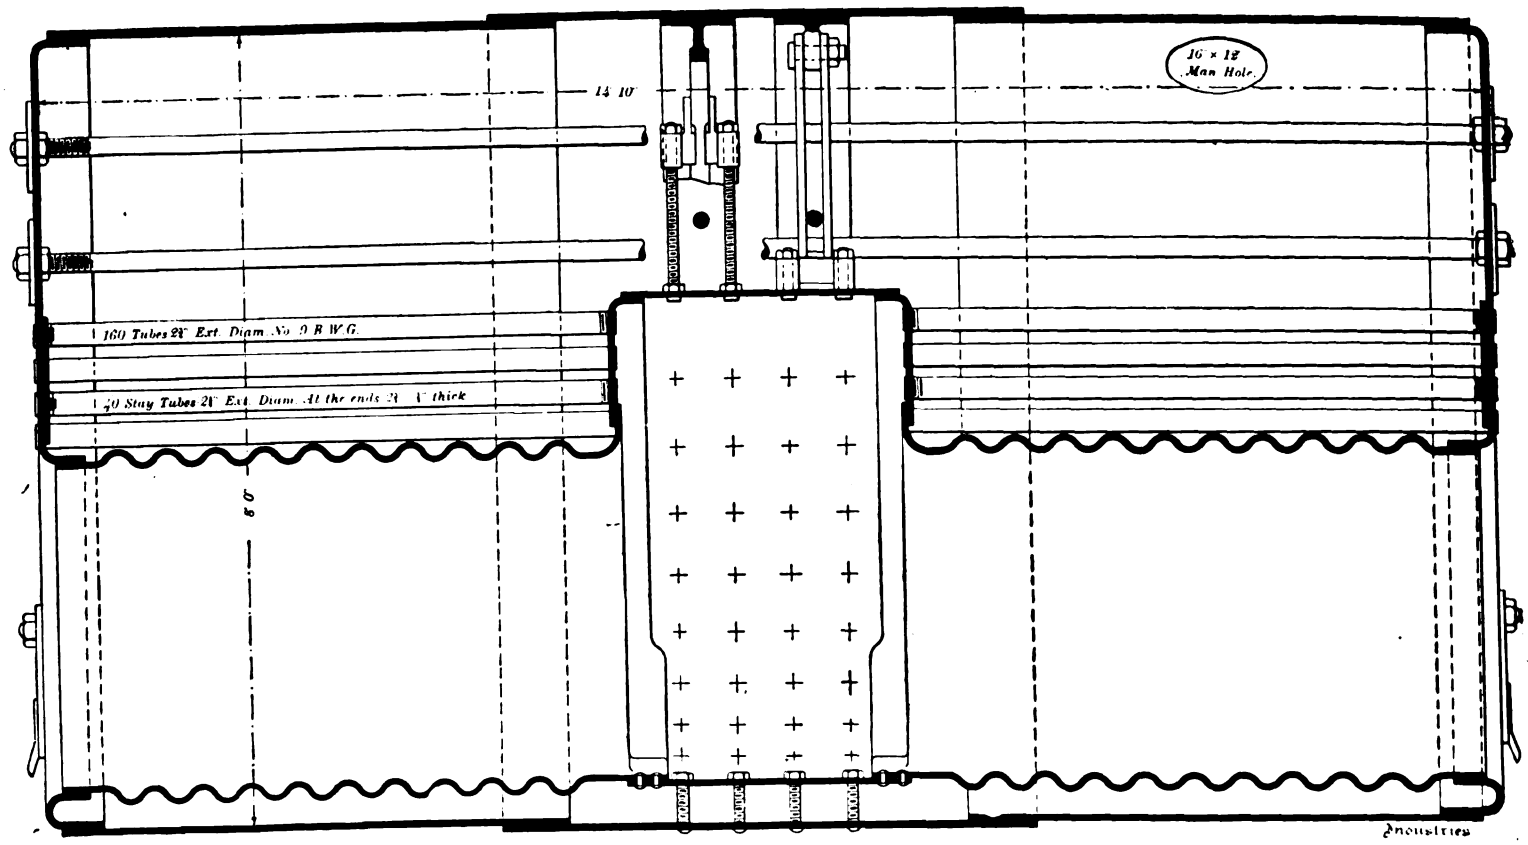

FIG. 7.—LONGITUDINAL SECTION.

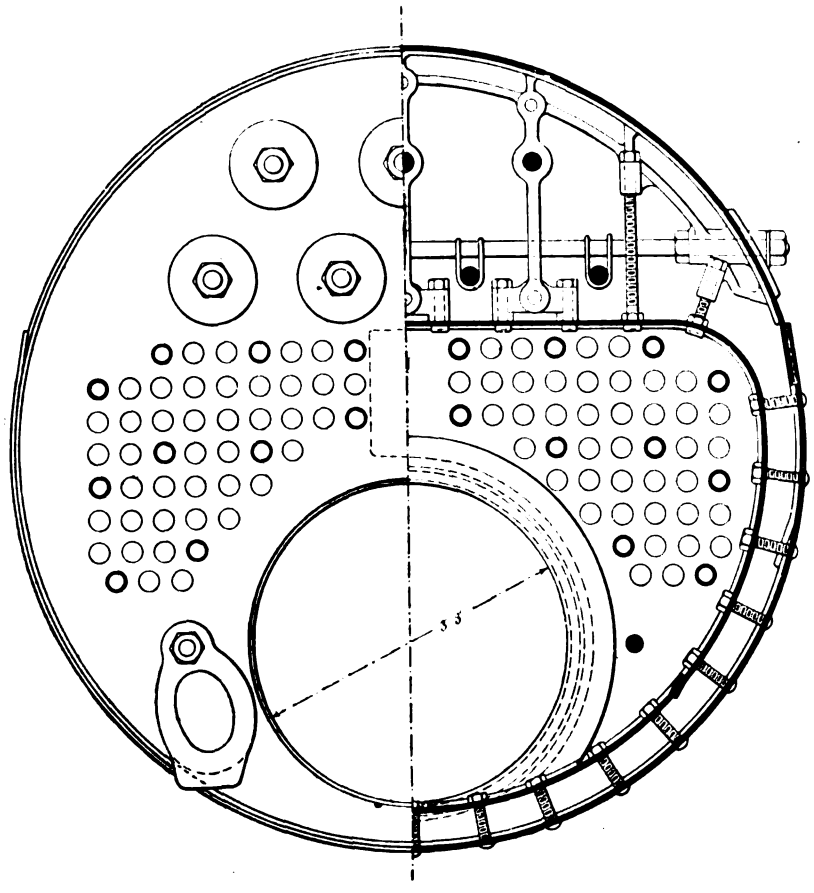

FIG. 8.—TRANSVERSE SECTION.

ENGINES AND BOILERS OF THE GUNBOAT "CERAM."

WE give above sectional views of the boilers of the gunboat "Ceram," and on page 62 and our two-page supplement for this week, will be found illustrations of the engines of this vessel, which is a gunboat belonging to the Dutch Colonial Navy. The engines are of the triple expansion surface condensing type, the cylinders being 20in., 29in., and 46in. in diameter, and the stroke 29in. The high pressure cylinder is fitted with a liner of Whitworth compressed steel ½in. thick, the space between the body of the cylinder and the liner being utilised for jacketing. The pistons are of cast steel, with junk rings of the same material, and fitted with Buckley's piston rings of much lighter section than usual. The slide valve of the high pressure cylinder is cylindrical, and is made in that form for the purpose of bringing the inlet steam to the centre of the valve. The intermediate and low pressure valves are flat, but work under a strong cover, with false ports, for relieving them of the steam pressure. The valve arrangement consists of Bremme's gear, with the eccentrics on the couplings of the crank shaft. The vertical rods of the gear are connected by a ball joint to a floating lever, which actuates the three valves. For reversing the engines a reversing engine is used having a 7in. steam cylinder, with 19in. stroke, cast in one piece with the intermediate cylinder, and placed between this and the high pressure cylinder. The piston rod of the reversing engine actuates, by means of a small connecting rod, a lever on the reversing shaft. The valve of the reversing cylinder is moved by a rod fixed to a hand lever, turning round a small eccentric on the reversing shaft, so that the valve is closed by a movement of the reversing shaft, equivalent to that given to the reversing handle. The reversing of the engines from full speed ahead to full speed astern is brought about in two seconds. The reversing shaft is carried in a pipe cast in one piece with the guide of the high pressure crosshead. It will be seen from the illustrations that the pin forming the crosshead is attached by two bolts to the connecting rod. In this arrangement, the piston rod ends are solid and without any cover, so that the brasses can be easily adjusted to the pin with the connecting rod disconnected. The brasses are closed up by a wedge worked by a screw from the front of the piston rod, this position being much more convenient than that of the nuts of the ordinary cover. The piston, connecting rods, and the crank shaft are made of steel, the latter being made in three equal parts. The corners of the crank webs are cut off, as shown, in order to reduce the weight. The bed plate is made entirely of cast steel, and as light as possible while maintaining the necessary strength and rigidity; the total weight being only two tons. The foundation in the ship is formed by heightening the frames, and bending them into such a shape as to fit the bed plate. The shaft brasses have no flanges, but are kept in place by pins fitting into holes bored in the bed plate and cover. The eccentrics on the couplings are also without flanges, so as to leave the eccentrics free to move forward and backward with the shaft without bearing against the eccentric rings. The air and circulating pumps are single acting and cast in one piece. They are made of brass, while the feed and bilge pumps are of gun metal.

The columns supporting the cylinders consist of drawn steel tubes, 3in. external diameter, and ⅜in. thick; but turned out of tubes ⅝in. thick, to get the necessary thickness in places where holes had to be bored through them. At the ends where they fit into the bosses on the cylinders and bed plate, they are forged to a smaller diameter, giving greater thickness of metal where the thread is cut. The condenser is made entirely of copper, the shell having corrugations at intervals, instead of the rings usually riveted on to it, to strengthen it against collapse; and the covers have radial corrugations for the same reason. Condensers made on this system are light, and have the additional advantage of having no rivet holes.

There are two double ended boilers of 8ft. 2in. diam. and 15ft. in length, with one corrugated furnace at each end of 3ft. 3in. mean diameter. The working pressure was fixed by the naval authorities at 120lb., as, at the time when these engines were designed, a higher

Digitized by Google

pressure was not customary, especially for ships stationed in India. The boilers are made entirely of Siemens-Martin mild steel, all holes being drilled in position. The whole of the riveting was done by hydraulic riveters. It will be observed that the top of the combustion chamber is stayed in a rather unusual manner; but the builders think that this plan, or something equivalent to it, is the most effective way for strengthening this part of the boiler. They argue that so long as the boiler shell is utilised for staying the combustion chamber in the ordinary way, no other resistance can be obtained than that due to the stiffness of the shell plate, for the shell being in equilibrium may be deformed to a comparatively large amount before any considerable resistance is obtained. In the usual method of shaping the sides of the combustion chamber, the required tension on the stay bolts is only effected by the two outer rows acting as struts and keeping the shell plate in its circular form, the part of the plate between these two rows acting as girders for the middle row of stays.

In boilers where steam pressures of 180lb. to 200lb. are to be used, this staying of the sides of the combustion chamber to the shell will have to be carefully attended to, otherwise leakages or accidents may occur. Referring to Fig. 7, it will be observed that there are two bridge stays in the middle of the breadth, which are arranged to allow a man to pass from one end of the boiler to the other. The bridges to which the vertical stays are attached have I section, and are made of cast steel, the outside being turned in the lathe to a true circle, and afterwards riveted to the shell. Forced draught can be supplied by closing the stokeholds, the air being drawn from the engine room and forced into the boiler space by a fan of 5ft. 6in. diam., made by Messrs. Allen & Co., of London. An air pressure of 2in. of water is easily obtained; but this pressure was not fully utilised at the trial trip. With about half that pressure, the engine indicated 804 h.p., against 606 h.p. as obtained with natural draught. The propeller is made entirely of Delta metal, and the ship is composite and sheathed with brass, and has the following dimensions: Length, 150ft.; breadth, 25ft. 6in.; mean draught, 9ft. 4in.; displacement, 510 tons. Referring to our illustrations, Figs. 1 and 2 show front and end elevations of the engines and Fig. 3 a plan; Fig. 4, slip and resistance curves while running with a four bladed propeller, and also with two blades removed. Figs. 5 and 6 show a longitudinal section and end elevation of the condenser, and Figs. 7 and 8 longitudinal and transverse sections of the boilers. We understand that the engines, when running at their full power, and at 130 revolutions per minute, worked with very little vibration.

SHIPBUILDING NOTES.

On Saturday afternoon the s.s. "Endeavour" was successfully launched from the shipbuilding yard of Messrs. R. Stephenson & Co., Limited, Hebburn. This is the first vessel that has been launched by the firm, but preparations are being made for carrying on shipbuilding work on an extensive scale, and already several orders have been booked. The dimensions of the "Endeavour" are as follow: Length, 300ft.; breadth, 40ft.; depth, 27·1ft.; and 2500 tons gross register. She is intended for general trade, but will be fitted with lofty 'tween decks for carrying emigrants. She will also be fitted with "sentinel" steam gear by Alley and McClennan, of Glasgow, Harfield's patent steam windlass, water ballast and double bottom, and triple expansion engines of 200 n.h.p. She is being built to the order of Messrs. McIntyre & Co.

The Blyth Shipbuilding Company, Limited, launched from their yard at Blyth, on Friday last, a finely modelled screw steamer, 242ft. long, 33ft. beam by 16½ft. depth of hold, built for the firm of Messrs. W. Lamplough & Co., of London. The vessel is built on the "well-deck" principle, with long, raised quarter deck, bridge amidships, topgallant forecastle, customary water ballast arrangements, and to Lloyd's highest requirements. The cabin accommodation is under the bridge deck. There are four large hatches for cargo, and alongside are four of John Smith and Sons' powerful steam winches. Harfield's patent windlass is placed on the forecastle deck. Donkin and Nichol's patent combined steam and hand steering gear is fitted in the wheel house on the bridge deck, and hand steering gear aft. The engines are of the triple expansion type, of 150 n.h.p., and will be fitted by the North-Eastern Marine Engine Company, Wallsend. As the vessel left the ways she was named the "Godmunding" by Mr. John Nixon, of Blyth. Immediately after the launch the vessel was towed to the Tyne by two powerful Blyth tugs, to have her engines and boilers placed on board.

On Saturday morning the fine steel steamer "Locksley Hall," which has been built by Messrs. Palmer & Co., Jarrow, for the well known "Hall" Line, was taken to sea for her trial trip. She is a vessel with splendid accommodation for some sixty first class passengers, and is 380ft. long, 45ft. broad, and 30ft. deep.

There was launched from Messrs. W. B. Thompson & Co.'s shipbuilding yard, at Dundee, last week, what is believed to be the largest and most powerful steam tug afloat. She is a vessel of 750 tons gross register, is fitted with engines 400 n.h.p., and will be propelled by twin screws, each driven by an independent engine. Her dimensions are: Length, 218ft.; breadth, 31ft.; and depth of hold, 15ft. 6in. The tug is built for the Retriever Steamship Company, Limited, Liverpool, and has been made suitable for towing purposes on the Hooghly.—A vessel built by the same company for the same service a year or two since was purchased by the Government. She is now known as H.M.S. "Hearty."

Messrs. Harland & Wolff, Belfast, have just completed one of the largest sailing vessels afloat for Messrs. Brocklebank and Co., Liverpool. She has been named "Sindia," and is rigged as a barque with four masts; and her gross tonnage is 3060.

Notices of Meetings.

THIS WEEK.

ARCHITECTURAL ASSOCIATION.—Friday, 20th January, 7·30 p.m. Ordinary meeting. Paper to be read by Mr. Somers Clark, F.S.A.

ROYAL INSTITUTION OF GREAT BRITAIN.—Saturday, 21st January, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

NEXT WEEK.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 24th January, 8 p.m. Ordinary meeting. Paper to be read with a view to discussion, "The Erection of the 'Jubilee' Bridge carrying the East Indian Railway over the river Hooghly, at Hooghly," by Sir Bradford Leslie, K.C.I.E., M.Inst.C.E.—Friday, January 27th. Students' meeting. Paper to be read on "Pumping Machinery in the Fenland and by the Trentside," by Mr. Lawrence Gibbs, Stud.Inst.C.E.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, 24th January, 3 p.m. Lecture on "Before and After Darwin," by Dr. G. J. Romanes.—Friday, 27th January, 9 p.m. Lecture on "The Exploration of Masãi Land," by Mr. J. Thomson.—Saturday, 28th January, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

LIVERPOOL ENGINEERING SOCIETY.—Wednesday, 25th January, 8 p.m. Discussion on Mr. A. W. Brightmore's paper, on "Some Recent Experiments on Iron and Steel and Riveted Joints." The subject of "The Architects' and Engineers' Registration Bill, 1888," will be introduced by Mr. J. Price.

SOCIETY OF ARTS.—Wednesday, 25th January, 8 p.m. Ordinary meeting. Paper to be read on "Theatres, and Fireproof Construction," by Mr. Walter Emden.—Friday, 27th January, 8 p.m. Indian section. Paper to be read on "The Public Health in India," by Mr. Justice Cunningham.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—Thursday, 26th January, 8 p.m. Ordinary meeting. Discussion on Mr. C. Cockburn's paper, on "Safety Fuses."

PRICES CURRENT, 19TH JANUARY.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—A fall of from £10 to £12 has occurred since our last, prices having touched £74. 15s., since which the market has recovered, the price being £75. 5s. to £75. 2s. 6d. as we write. This appears to be influenced by the action of the syndicate, who are now said to be treating with some of the largest producers of copper, so as to arrange for the command of their output for the next two or three years. Their object is stated to be to maintain the prices at a higher level, by regulating the output, and preventing the price going below a fixed basis, which is understood to be about the present price of Chili bars. The position of copper does not therefore appear to be greatly affected by this fall, as "strong" copper remains firm and is no lower. The supply of copper is no larger, and the stock is mainly held by a powerful syndicate, who are quite able to handle it. Trade in all branches of the copper manufacture is very slack, and will continue so until uncertainty changes to a confidence in the stability of the new basis of value.

TIN remains firm and prices unaltered, the whole stock being firmly held by a strong syndicate.

LEAD is a little easier, the supplies being large.

SPELTER is a little easier, but the stocks are small and the demand active.

MACLAINE'S PATENT PERFECT PISTON COMPANY, LIMITED.—At the annual meeting of the shareholders of this company, held on the 13th inst., a dividend of 100 per cent. free of income tax for the year 1887 was declared.

INTERNATIONAL GEOLOGICAL CONGRESS.—The fourth session of this Congress will be held in London this year from September 17th to 22nd, both inclusive. The organising committee have nominated Professor Huxley as honorary president, and Professor Prestwich as president.

Digitized by Google

HOME INDUSTRIES.

MANCHESTER, 19th January, 1888.

The Bolton Strike.—Our readers will remember the protracted strike of engineers which occurred during the past year at Bolton. When work was resumed it was agreed to leave the matters in dispute for settlement by a Board of Arbitration, in which both parties were represented. On the failure of these negotiations the case was submitted to Mr. S. Pope, Q.C., as arbitrator, who, on the 16th inst., announced his decision. Stated briefly, his judgment was to the effect that no reason for an advance of wages existed, and that the men were not entitled to it. The result, therefore, of the long fight and its attendant annoyances and loss, is to leave matters precisely as they were. It is to be hoped that the Board of Arbitration will not be disbanded, but will be enlarged and formed into a body by which all such disputes may be settled in a rational manner.

The Cotton Trade.—The situation is much the same as at the time of our last notice of this trade. Continuous contest is going on between buyers and sellers, in which neither, speaking broadly, are gaining much ground. So far as export yarns are concerned, the notable feature is an increase of shipments to the Continent; but in most cases the offers for this class of yarn are low, and not acceptable to spinners. The latter are, however, holding their own, and in special lines, such as bundled yarn, prices are very firm. The fluctuations of the cotton market have no marked effect upon spinners, nor do they induce business on the part of buyers. Manufacturers find it extremely difficult to obtain new contracts in the place of the old ones at the prices which they desire to get. At the same time, in most classes of goods there is no disposition to accept the low prices offered, and the result is that very little business is being transacted. The persistently low offers which they are receiving deter them from placing orders for yarn except at lower rates, and the market all round is quite free from any tendency towards large buying.

The Iron Trade.—The market for pig iron is very little influenced by the weaker tone of the Glasgow and Middlesbrough markets, and makers are holding very firmly to quotations. In bar iron, however, a stronger tendency is observed, common bars being now quoted £5. 2s. 6d. to £5. 5s. per ton; and the iron merchants of the district have advanced their quotations 10s. per ton for bars from stock. The very low rates prevailing for common bars have long been unprofitable, and the present advance is consequently quite justified.

The Ship Canal.—The call of £1 per share due on the 16th inst. has been well paid, and a gratifying feature is that a large number of the persons meeting the call have paid up their shares in full. This fact indicates that although Stock Exchange quotations are still much below par, there is nevertheless public confidence in the work. The construction of the Canal is making satisfactory progress, and it is reported that at the Eastham end the work is advancing rapidly, and that a large amount of plant is already on the spot.

LONDON, 19th January, 1888.

The Money Market.—The reduction in the Bank rate has not made any difference to the course of the money market. The Bank rate fulfils a useful function of its own, but it has ceased altogether to affect the current rates for money. These remain very easy, and the demand is slight. The stock markets are excessively dull in every department. The railway dividends announced so far have been disappointing, and have depressed the stocks of the companies concerned, and there has been a general feeling of dulness in home railways. British funds have been adversely affected in sympathy with a drop in the foreign market. So far there is no perceptible and distinct reason for this feeling abroad, but there is an instinctive dread of coming complications. A feature of the week has been the forcing down of the price of copper by the Paris syndicate, which is determined to spoil the market for those mining companies which have refused to come to terms with the conspirators. It is rather hard that the mines which have striven thus to act fairly to the consumers, and to preserve their own independence, should be thus victimised; but the occurrence shows how completely the syndicate has the market at its mercy. The shares of the copper companies have not fallen, as they would have done had the reduction in the price of the metal been a legitimate trade movement, and not a mere phase of a corner.

Companies.—Since our last report the following new companies have been registered: The Italian Gold Mining Company, Limited (California), with a capital of £90,000; Claringburn, Wilde, & Co., Limited, with a capital of £15,000, to purchase the business of a hosiery machine builder, carried on by Mr. J. A. Claringburn in Liverpool-st., Nottingham; the Thomas Lamp Company, Limited, with a capital of £50,000; Death's Fibre Machine Company, Limited, with a capital of £12,000; Anglo-American Bangor Slate Company, Limited, with a capital of £120,000; the Mannesman Tube Company, Limited, with a capital of £300,000; Stephen Thompson & Co., Limited, with a capital of £50,000, to carry on business at Wolverhampton as tin plate manufactures and iron masters; the Type Setting Syndicate, Limited, with a capital of £50,000, to acquire the patent rights in Great Britain of the Thorne type setting and distributing machine (described in *Industries*, Vol. III., page 69); Credenda Seamless Steel Tube Company, Limited, with a capital of £100,000: Foxes Bridge Colliery Company, Limited, with a capital of £121,000; Anglo-Sheba Gold Mining Company, Limited (Transvaal), with a capital of £70,000; Goldfields of Uruguay, Limited, with a capital of £300,000: Rocky Bar Wide West Gold, Limited (U.S.A.), with a capital of £120,000; Cerro de Pasco (Transvaal) Goldfields, Limited, with a capital of £375,000; Boord & Son, Limited, with a capital of £600,000, to carry on business as distillers, brewers, &c.; the Hull Brewery Company, Limited, with a capital of £200,000; and F. H. Lloyd & Co., Limited, with a capital of £20,000, to carry on business at the James Bridge Steel Works, near Wednesbury, as steel founders.

The Board of Trade Returns.—The favourable tendency of trade shown in the November Board of Trade returns is maintained in those for December. The total exports for that month amount to £20,385,464, an increase of £3,231,954, or 18·9 per cent. over those in December, 1886; and the imports amount to £34,173,968, an increase of £3,162,685, or 10·2 per cent. The exports of iron and steel, machinery and mill work, hardware and cutlery, chemicals, wool, and cotton piece goods show marked advances. The total exports for 1887 amount to £221,398,440, being an increase of £8,965,686, or about 4 per cent. over 1886; the total imports amounted to £361,935,006, an increase of £12,553,920, or about 3·5 per cent.

Iron and Steel.—As mentioned in the foregoing paragraph, the exports of iron and steel for the month of December show a large increase, the value being £2,191,485, as compared with £1,723,983 and £1,588,782 in the corresponding month of 1886 and 1885. The value for the year was £25,000,336, against £21,817,720 and £21,710,738 in 1886 and 1885. Italy and the United States have largely augmented their purchases of pig iron, and the latter country has also bought bar, angle, bolt, and rod iron largely. British East India has drawn on us for a great quantity of railway material. Exports of unwrought steel to the United States show a decrease.

Textiles.—Although prices of wool during the past year fluctuated to some extent, the rise and fall were not very marked as a rule, and the rates, taken generally, were much the same at the end of 1887 as at the same period of the previous year. The condition of the trade is very sound, although prices are below the average of the past ten years. In the hemp market there has been but little doing, but there has been an improved demand for Manilla.

Shipbuilding.—In their review of the past year's shipping trade, Messrs. Angier Brothers point out that the tonnage output of 1887 shows a large increase on that of 1886, and yet the majority of builders have turned out far less than half the tonnage their yards are capable of producing. Under these circumstances it is easily explained why prices remained until quite recently at £6 to £7 per ton for ordinary cargo boats, and in proportion for the finer class, and about £10 per ton gross register for sailers. Owing to the rise in metals which commenced in October, the prices of new steamers have now advanced about 10 per cent.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 8th January, amounted to £1,069,354 on 15,830¾ miles, as compared with £1,021,023 in the corresponding period of 1887, when the mileage was 15,706¾ miles. An increase is thus shown in the mileage of 123¾, or 0·7 per cent., and in the receipts of 4·7 per cent.

Harbour Works at St. Heliers, Jersey.—The construction of the new harbour works at St. Heliers is proceeding rapidly, under the direction of Mr. W. R. Kinipple, of 2, Westminster Chambers, London, in succession to Sir John Coode. Dredging operations are being carried out, and a length of 200ft. of the new breakwater is already built.

The Bankruptcy Act, 1883.—A return has been issued showing that the number of receiving orders in the High Court and in the County Courts having bankruptcy jurisdiction was 4838 during 1887, as compared with 4860 in 1886, and 4345 in 1885.

The Use of Accumulators for Telegraphic Purposes.—For some time past the Exchange Telegraph Company has been using E.P.S. accumulators to work the Stock Exchange "tapes" from their office in Cornhill, with very satisfactory results. There have been employed 210 accumulators, arranged in three series of seventy each, in place of 2000 primary batteries, which were previously installed for the same purpose.

GLASGOW, 19th January, 1888.

General Trade.—Judging by the increase in traffic on the Scottish railways, the improvement in general business seems to be diffusing itself over the whole country. The aggregate increase for the week is about 10 per cent. Shipbuilding orders have for the time ceased to come in. Dulness has supervened both in the iron market and on the Stock Exchange, and after the sudden revival people are beginning to inquire whether there will be any permanence in the improvement.

Shipping.—The shipments of pig iron during the past week were 5934 tons. Coals show a falling off of about 20 per cent. Freights outwards are still firm. Those homewards are, as a rule, not so high. The Bombay Indentors' Association have renewed their agreement with the three Glasgow-Indian lines—the Anchor, the City, and the Clan—for freights between Glasgow and Bombay. It is an indication of the hardening of freights that the rate under this agreement has been advanced 2s. 6d. per ton.

Copper.—The movements in the copper market are of exceptional interest in local circles, because one of the chief producing companies—the Tharsis Company—has its head quarters here. The *Glasgow Herald* is responsible for the publication of a rumour to the effect that a preponderating influence in this company is being gradually acquired by French shareholders, who have always taken a large interest in the concern, there being several French directors on the Board. The Mason and Barry Company and the Tharsis Company have both held out against the French copper corner, and it is not unreasonably supposed that this French buying of Tharsis shares, and the simultaneous drop of £5 in the price of copper, are dictated by the same necessity, viz., that of bringing these companies to terms.

Iron.—The price of iron has experienced a sharp fall. It is said that this has been due to the efforts made to reap the benefits of the recent advance by those who had brought in the rising market, and also to the operations of speculators who are "bearing."

Edinburgh Cable Tramways.—Though these tramways are now nearly completed, and though one section at least might be opened to traffic, a dispute, which is now the subject of litigation in the Court of Session, has prevented them from being opened. A provisional arrangement, at the suggestion of the Court, has been made, by which the tramway will be inspected by engineers, and a certificate granted if their report is satisfactory.

Cassel Gold Company.—The directors of this company have made a call of 2s. 6d. per share upon the new shares. The fluctuations in the value of these shares have been periodically sources of excitement on the Stock Exchange. From a discount of 1s. they went up in a few weeks to 19s. 6d., a premium of 9s. 6d. They have since fallen back. On the day of the announcement they fell 3s., and reached 13s. 6d. The experiments are still progressing.

Physical Society of Glasgow University.—A meeting of the above Society was held on Friday evening in the Physical Laboratory of the University; Mr. Maclean, president, in the chair. An interesting paper on the "Testing of Lubricants," was read by Mr. Bunji Mano, M.E. The paper gave a description of results obtained from experiments made by the author in the University of Tokio, Japan. Besides giving an account of the apparatus and the method of experiment employed, Mr. Mano called special attention to the fact that in estimating the value to engineers of various lubricants, their constancy of action in keeping a cool surface with a low co-efficient of friction and a high temperature of decomposition was of much more importance than their cash value.

New Railway Bridge.—The two main girders, each weighing about 90 tons, of the new bridge over the Glasgow and South-Western Railway, at Stevenston, Ayrshire, have been placed in position. The girders had been constructed upon a wooden stage, and were erected at right angles to the line, so that by slewing round one end they reached their permanent position. The girders have been erected by Messrs. James Goodwin & Co., of Motherwell.

(From our own Correspondents.)

LIVERPOOL, 18th January, 1888.

The Vyrnwy Water Works and the River Mersey.—At a recent meeting of the Water Committee, Mr. Deacon, the water works engineer, submitted plans and a report made in accordance with instructions received after the Board of Trade inquiry, held a few weeks ago, of the proposed method of carrying the water mains underneath the bed of the river Mersey. Two alternative plans were shown; one with a tunnel carrying three lines of pipes, the other with a tunnel for carrying one line of pipes. The latter plan was adopted, and ordered to be submitted to the Board of Trade for approval. The engineer also submitted to the same meeting a drawing and report of a deviation of the Great Western Railway, agreed upon by the engineer of the Great Western Railway and himself. The committee also approved of a plan and report of a deviation of the line of culverts from the straining tower. The tender of Messrs. Davis Brothers for executing work in connection with the inlet and outlet of the Llanforda and Cynynion tunnel, and the Morda syphon pipe, was recommended for acceptance. It is expected that the dam will be closed next October, when the new lake will at once commence forming, thus enabling the new supply of water to be delivered in Liverpool a few months afterwards.

The Proposed South End Ferry.—At the last meeting of the Mersey Docks and Harbour Board, the recommendation of the Works Committee, that the Board refuse the application of Mr. R. A. Macfie to construct a floating landing stage at the South End, was carried by fourteen votes to five. The argument against the construction of such a pier and landing stage was that the ferry would be fraught with inconvenience to the traffic of the great system of docks at the South End; and judging from a case recently before the Court of Passage, might put considerable responsibility upon the Board. Mr. A. Holt said a high level railway would meet all the requirements. On the other hand, it was stated that if only few people used the ferry there would be no inconvenience, and if many used it, it would show that such a thing was needed. There is great

Digitized by Google

disappointment manifested at the decision of the Board, especially at the South End; for it was hoped that with the construction of this pier, and the consequent increased traffic to the Ship Canal works, the present depressed state of trade in this neighbourhood might be revived. The question will not be allowed to rest here, and further action in the matter will be taken.

SHEFFIELD, 18th January, 1888.

Iron and Steel.—Notwithstanding the smallpox epidemic, which is at present harassing the local trade, and interfering with operations at a few works, there is great activity in the heavy branches. Manufacturers find their order books filling more readily than in the first quarters of the past seven or eight years, and the iron and steel markets are still firm, with a tendency to advancing prices. The war rumours have had the effect of making Messrs. Thomas Firth & Sons very busy on gun material; and it is anticipated that Messrs. John Brown & Co. and Messrs. Charles Cammell & Co. will obtain extensive orders for heavy ordnance from the Government. These concerns have recently laid down huge plant for the purpose of manufacturing such ordnance; and it is a significant fact that Herr Krupp, of Essen, who was through the Atlas Works at the end of last week, has ordered for his gun works a large hydraulic forging press, similar to the one he saw at Messrs. John Brown & Co.'s. It is said that Messrs. Tannett, Walker, & Co., hydraulic machinery makers, of Leeds, have obtained the order, and that it may be followed by further demand for machinery of this character from the same quarter. Steel rails are selling easily at advanced quotations, and tyres find a market at an advance of 10s. per ton. Railway springs are also in active demand; indeed, there is a healthier inquiry for all classes of railway material. Shipbuilding material is more urgently required than it has been for some months past, and Messrs. Vickers, Sons, & Co. have large orders on hand for marine work. Orders for armour plates come in tardily; but the two armour plating firms—the Atlas Works and the Cyclops Works—are engaged on the turrets of the "Nile" and the "Trafalgar," which are giving a good deal of employment. In sheep shears and edge tools trade is brisk, chiefly on Colonial account. The stove grate makers are moderately busy in Sheffield, but at Rotherham the Wheathill Foundry Company have given their moulders and other workmen a fortnight's notice of reduction of wages, and the men have intimated that they will resist the reduction. The activity in the iron trade has spread beyond the Sheffield border. The Sheepbridge Iron Company are doing a much better trade in pig; and the blast furnaces at Ilkeston, after being idle for two years, have been blown in within the past few days.

NORTH STAFFORDSHIRE, 18th January, 1888.

The Iron Trade.—At the quarterly meeting held at Birmingham last week, some good orders were secured for this district. In finished iron a slight advance was obtained on the lowest rates which prevailed last year, while in pig iron an advance of 3s. to 4s. per ton was asked by producers. In the latter, however, most consumers are fully bought for the next three months at late rates. It remains to be seen whether the improvement in price can be maintained until they are again in the market.

Crewe Locomotive Works.—The men employed in the London and North-Western Railway Company's works are still on short time, and in face of the large stocks which have accumulated, there is not any immediate prospect of a change in present arrangements. A statement has been promulgated that a portion of these works are to be removed to Anderton, near Bolton, it being said that the lease of part of the company's property at Crewe was about to expire. As a fact the whole of the works are erected on freehold property, and additions to them are being constantly made, and there is no truth in the statement referred to.

The Cheadle Coalfield.—A company has been formed, under the title of the Cheadle Railway, Mineral, and Land Company, Limited, with a capital of £250,000, of which £100,000 is already subscribed and allotted, to construct a line of railway from Cheadle through the Draycott estate to Cresswell station, and among other things to develop the Cheadle coal basin, one-third of which has been secured by the company, and is estimated to produce over 60,000,000 tons of coal. Two pits have already been sunk upon one part of the property to a distance of seventy yards, and have reached the first seam of steam coal, 5ft. in thickness. The area acquired by the company for mining purposes consists of nearly 1300 acres.

BARROW-IN-FURNESS, 18th January, 1888.

Iron and Steel.—There is a falling off in activity in hematite pig iron and in steel rails. It is thought that this position has been brought about by speculators realising their stocks. Although quotations are lower, makers are very firm and well supplied with orders, and consequently can wait until prices improve. Pig iron is quoted at 44s. per ton net f.o.b. for mixed numbers of Bessemer descriptions, and at 43s. 3d. for No. 3 forge and foundry iron. Steel rails of ordinary heavy sections are quoted at £4 per ton net f.o.b. Billets are in brisker request at £4. 5s. per ton. Plates for shipbuilding are in very full demand, and are quoted at £7. 5s. per ton, with angles at £7. 10s. net f.o.b. There is prospectively a very brisk trade in shipbuilding material, and at Barrow arrangements are in progress for increasing the producing power at the steel works in this department. A new plate mill, which works most satisfactorily, has been started this week, and another mill is to be erected along with some additional Siemens-Martin furnaces. One or two very important orders for shipbuilding material have been placed during the week, and the local shipbuilding works are likely soon to be very busily engaged, as well in the shipbuilding as in the engineering departments.

Development of the Steel Trade.—It is proposed to erect Bessemer steel works in connection with the Whitehaven Hematite Iron Company's Works at Cleator Moor, in Cumberland. This is one of the oldest iron producing firms in the North-West of England, and although their works are situate some four or five miles from the coast, they are alongside of a valuable bed of iron ore, and quarries of suitable limestone for fluxing purposes; and the Company at Lowca, near Whitehaven, contemplate adding new mills to their plant for the manufacture of Siemens-Martin steel for ingots and castings, and the rolling of steel sheets and bars. At the West Cumberland Iron and Steel Works recent improvements have been effected to increase the output, and the same thing has taken place at the works of the Barrow Steel Company; while Messrs. Cammell, at Workington, have recently commenced a new rail mill.

Coal Prospecting.—It is thought that if coal exists at all on the Furness peninsula, it will be found at the southernmost point of Walney Island, because the dip of the mountain limestone is proved to run in that direction. A company have been boring with the diamond rock drill for some time past, and have reached a depth of 1450ft. They are still in the red sandstone, but expect soon to pierce the coal measures, if any exist at this place.

MIDDLESBROUGH, 18th January, 1888.

Pig Iron.—Since the commencement of the year the pig iron market has not fulfilled the hopes of the speculators who counted upon a continuance of the advance. For a time it remained firm at the price attained, but eventually it has gradually yielded, until 1s. 9d. of its gain has been lost. As low as 32s. has been accepted for No. 3 G.M.B. prompt, but 32s. 3d. is the average price per ton early delivery. Warrants are 31s. 10d. per ton cash, and hematite 43s. 6d. to 44s. 6d. per ton for Nos. 1, 2, and 3 mixed. Forge iron maintains its price at 32s. per ton, as the finished iron trade still retains its briskness, and the demand is good. The shipments of pig iron up to the 16th of the current month are not so good as in the month of December, being 25,895 tons, as compared with 40,282 tons; but they are much better than those over the same period in January, 1887, which were only 17,369 tons. The home consumption is much greater.

Manufactured Iron and Steel.—Finished iron maintains the improvement it made in the latter part of the year. Common bars are £5 to £5. 2s. 6d.; ship angles, £4. 15s. to £4. 17s. 6d.; engineering angles, £5 to £5. 2s. 6d.; sheets (singles), £6 to £6. 2s. 6d.; ship plates, £5 to £5. 2s. 6d.; boiler plates, £6 to £6. 2s. 6d. per ton less 2½ per cent. on trucks at manufacturers' works. Finished steel is not so brisk in the meantime, and prices have settled somewhat. Prices are—rails from £4. 2s. 6d., ship plates from £7, ship angles from £6. 10s. on trucks at works for cash less the usual discount. The North-Eastern Steel Works have been laid off since Christmas for repairs. The manager has taken occasion, as the time for resumption of work comes on, to insist that the men shall detach themselves from the Union of Steel Workers, and, if they like, form one of their own. The men object, and so the manager and men are in dispute, and in the meantime the men are locked out. Lloyd's surveyor has not yet visited the Eston Steel Works.

Shipbuilding.—The prospects of this industry in the district are bright and hopeful. Several of the orders recently given out have come to the Cleveland Dock Yard, whilst the other yards are said to be similarly situated in proportion to their capacity.

SUNDERLAND, 18th January, 1888.

Shipbuilding.—Gradually increased activity is becoming general in the local shipbuilding yards, owing to the laying down of steamers lately ordered. It has been stated that many of the orders recently booked were given out by parties speculating on a general and continued rise in the value of steam shipping.

Marine Engineering.—It is fully four years since the prospects of this important local industry were so promising. Every day brings additional activity. The alterations to the Scotia Engine Works are being carried on energetically, and it is understood that several orders for triple expansion marine engines have been booked by the proprietors.

The Shipping Trade.—During last week 68,205 tons of coal were shipped, as compared with 74,683 tons in the corresponding week of last year—a decrease of 6478 tons, largely due to the foggy weather delaying the arrivals and sailings of steamers. An even larger falling off, viz., 17,621 tons, was experienced at Tyne Dock. Coke, patent fuel, bottles, cement, fire clay goods, &c., were the remaining exports; the imports being iron ore and timber. Outward freights are somewhat higher, but there is no improvement in Black Sea, American, or homeward freights generally.

Iron Works.—Local rolling mills and forges are now well employed, especially the latter, the forging of keel and stem bars, stern frames, and heavy forgings for marine engines keeping five forges in operation day and night.

NEWCASTLE, 18th January, 1888.

Rope Works.—An active business is still to be noticed at each of the principal rope manufactories. Such establishments as Messrs. Haggie Brothers, Gateshead; Messrs. Hood, Haggie, & Sons, Willington Quay; and R. S. Newall and Sons, Washington, being particularly busy, owing to the fact that in addition to the home trade, their proprietors have many important foreign contracts in hand. Messrs. Dixon & Corbitt and R. S. Newall & Co. are also firms to which this remark may be correctly applied, the foreign contracts forming a very large proportion of the total work on hand.

Leather Works.—The improvement which has taken place in general trade has beneficially affected the leather industry in this district, and the change is especially noticeable in connection with the production of such descriptions of india-rubber goods as are used for engineering purposes.

Glass Works.—The Gateshead Stained Glass Company have developed a very active business lately, and they have now as many orders on hand as they can conveniently deal with, even by utilising their resources to their utmost extent. One of the contracts now in progress is the stained glass for a new church which is being erected at Jesmond, by Mr. Charles Mitchell, partner in the great firm of Messrs. Armstrong, Mitchell, & Co., Elswick. Pressed glass works at Gateshead, Lemington, and South Shields are still busy, and the plate glass company at the latter place is experiencing a rapidly increasing demand for their product. Such establishments as are devoted to the manufacture of lamp chimneys, globes, &c., are exceedingly busy; and the few remaining bottle works that are in operation, are much busier than they have been. The principle of making "metal" in "continuous tanks," instead of in the old fashioned "pots," has now been generally introduced into these establishments, and has had the effect of cheapening as well as accelerating the production.

Potteries.—The local demand for earthenware has been considerably stimulated of late, and as large orders for goods of this description are also coming to hand from distant centres, the continuance of the satisfactory state of business now existing is assured for some months to come.

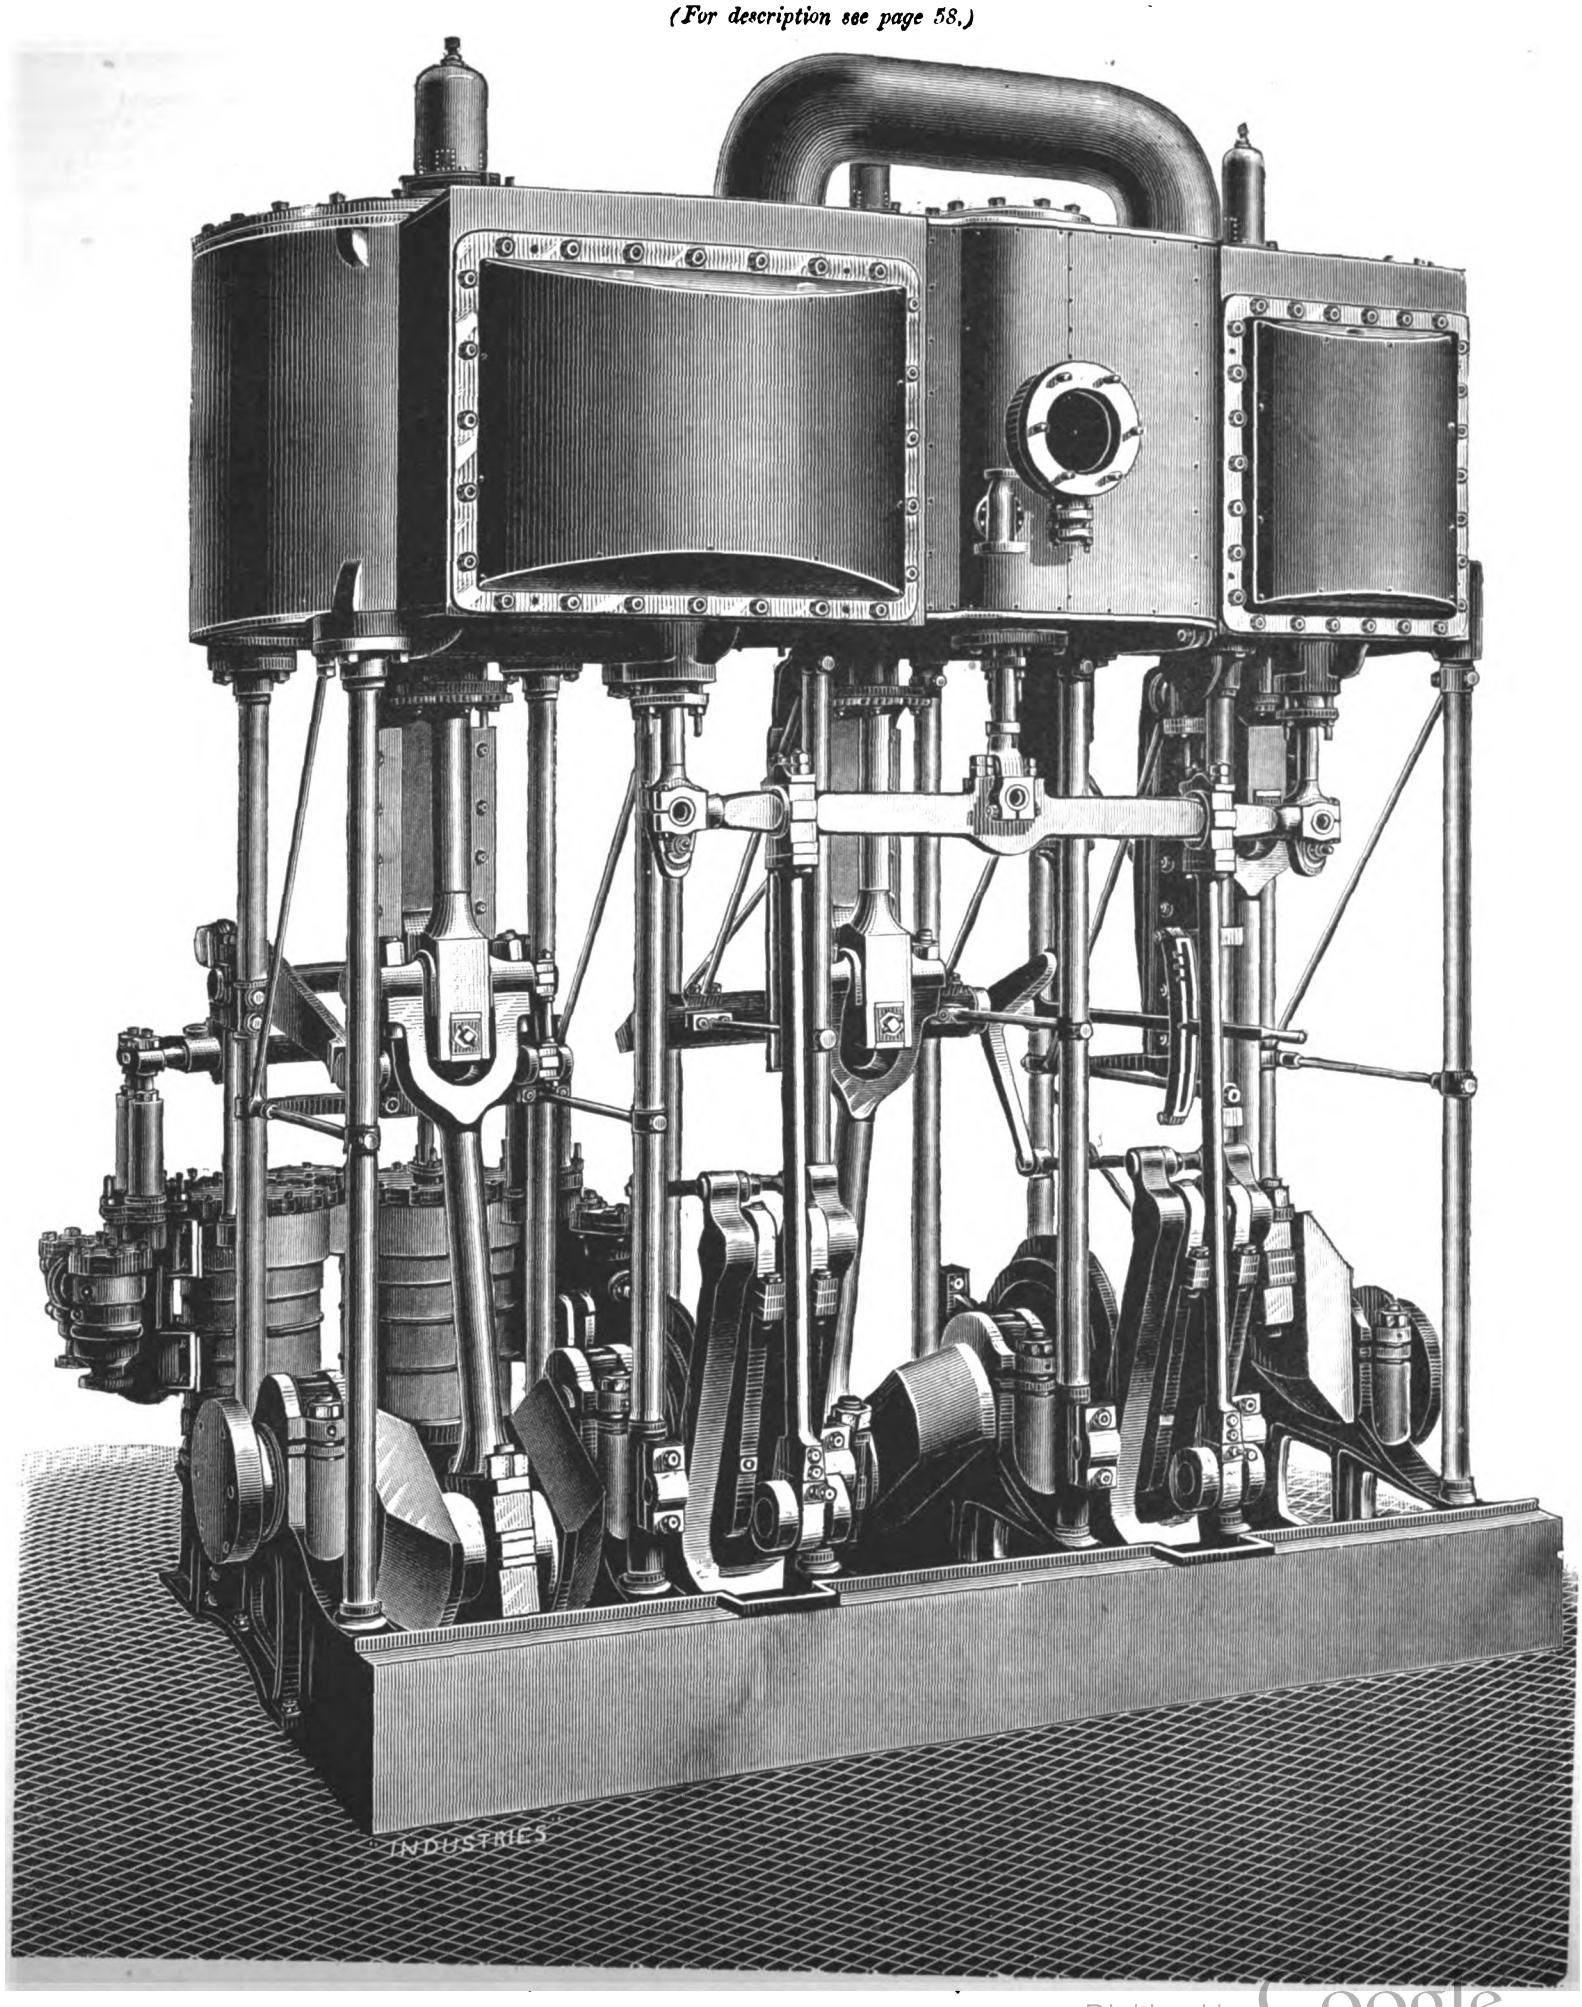
Soap Works.—Business at the local soap works is somewhat depressed at present, and the competition of other districts is proving particularly severe. Though a portion of their trade appears to have been temporarily diverted, manufacturers do not despair of being ultimately able to meet their competitors on equal terms, and they are making every effort to secure the early realisation of their hopes.

The Timber Trade.—Though the imports of timber have for the present practically ceased, business in the saw mills and timber yards has improved, the requirements for building purposes being at present more than ordinarily large.

DUNDEE, 18th January, 1888.

Flax and Jute Trades.—The staple industries of the town and district have been fairly active since the opening of the year. The market for raw jute has eased a little. Spinners have adopted a waiting policy, and some small lots afloat have changed hands at a decline of 5s. to 7s. 6d. from the highest point. Telegrams from Calcutta report no material change in the market there for baled jute; but with a falling off in the arrivals of loose jute, and as the owners of the Calcutta mills are large buyers, no material decline in price is anticipated. Jute yarns meet a quieter demand, and prices in some instances have been barely maintained. In jute fabrics the demand has also fallen off a little, and the tendency has been rather against sellers. Sacking is still wanted, and prices are firmly maintained; but the demand for bagging and tarpaulin has not been quite so active, and buyers have if anything the advantage. In flax there has been more doing on the spot for assortment purposes, at about previous rates. On contract there is a fair business passing, and prices are steady. Transactions in tow and codilla are of small extent. Flax and tow yarns are in fair demand, and spinners are inclined to hold for a small advance; but bleachers, so far, are still sellers at the old rates. Orders for linen goods have come in more freely since the holidays, and some good orders from the home trade were placed last week. The foreign demand has also improved, and manufacturers are understood to be well engaged for some time. Sailcloth is steady, but the demand is still limited.

Electric Lighting.—A new carpet factory erected here has just been fitted up with five hundred electric lamps. The dynamo is one of Messrs. Mather & Platt's, and is worked by the engine which drives the looms.



Shipbuilding.—The Dundee Harbour Trustees have accepted an offer from Messrs. Pearce Brothers to build for £6,700 a steel tug fitted with two sets of triple expansion engines, each engine to be of 48 h.p. nominal. The cylinders will be of 12in., 17in., and 30in. diam., and 20in. stroke. Her dimensions will be: Length, 120ft.; breadth, 24ft.; and depth of hold, 10ft. 8in.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Industries:

FRIDAY, 20TH JANUARY, 1888.

THE INDUSTRIAL IMPORTANCE OF ELECTRICITY.

THE subject chosen by the President of the Society of Telegraph Engineers and Electricians for his inaugural address cannot fail to be highly interesting not only to engineers and electricians, but also to manufacturers of machinery and apparatus required in the practical application of electricity. In this address an attempt has been made for the first time to express in figures the importance of the various trades depending upon the operation of electricity in one form or another. It has often been said that the elaboration of a presidential address for any of our learned societies becomes more difficult from year to year as the available ground becomes to an increasing extent occupied by previous addresses, and considering the large number of able men who have preceded Mr. Graves in the presidential chair of the Society of Telegraph Engineers and Electricians, he had no easy task before him if he would tell the Society something which would be both novel and of practical interest. He has, however, acquitted himself of the task in a manner which leaves nothing to be desired. His address dealt with a subject which is novel in the sense that nobody had previously taken the trouble to investigate it, and which at the same time is of the highest practical importance, because of affecting more or less directly the worldly prospects of his hearers. The President's high official position made it possible for him to obtain information of the number of persons employed in various branches of applied electricity, both in the manufacture of electrical machinery and apparatus, and in the working of industrial enterprises based on the use of such machinery and apparatus. These figures he has now published, and the world is for the first time in a position to form at least an approximate estimate of the industrial importance of applied electricity.

The estimate refers, however, only to those persons who earn their living by the application of electricity in one manner or another, but it does not comprise the far greater number of persons who are indirectly benefited by this agency. If a manufacturer, a merchant, or a private individual sends a telegraphic message, he does so because he expects to derive some benefit from the more rapid means of communication as compared to the sending of a letter or a special messenger. This benefit in some cases cannot be expressed by a monetary standard, but in the majority of cases it is simply a financial benefit, measurable in £. s. d. By use of the telegraph, orders are more promptly executed, time is saved, supplies can be secured in the cheapest markets, and the cost of production reduced, whilst, on the other hand, the value of the manufactured article is enhanced by greater opportunity for effecting a sale which naturally follows the improved facility of communication with various consumers. Thus the operation of the telegraph tends to enhance the amount of wealth produced by human labour, and at the time when the Government took over the telegraphs in this country it was roughly estimated that a sum of 10s. represented the commercial value of each telegraphic message. Since then, telegraphy has enormously expanded, and the commercial value of each message is probably considerably greater than was then estimated. With this aspect of the case, however, the President did not deal. He confined himself to enumerating the benefits accruing to the persons immediately engaged in electrical pursuits. In limiting his investigations to this branch of the subject, he had the advantage of being able to deal with it in a strictly scientific manner, omitting all guess work and conjectures, and including only such facts as could absolutely be substantiated by figures. There can be little doubt that in his anxiety to present to the Society only that which is absolutely reliable, he rather under than over estimated the number of persons directly engaged in electrical pursuits; but the relative proportion between the different numbers of persons engaged in the different branches of electricity is probably correct. The following is a list given by Mr. Graves of persons employed in Great Britain. We have added to each item the percentage of the total, so that the relative importance of the various trades may become apparent:—

Employed in connection with	Number of Persons.	Percentage of Total.
British Land Telegraphs	23,868	56·3
Submarine Cable Companies (mainly British)	6,000	14·2
Telephone Companies	2,500	5·9
Electric Lighting	5,000	11·8
Cable Making and allied businesses	5,000	11·8
	42,368	100

Mr. Graves estimates that the total number of persons employed in land telegraphs throughout the whole world is 180,000; in telephones, 30,000; and in electric lighting, 100,000. Confining ourselves, however, only to the figures for Great Britain, we must remark that the total of 42,368 relates to persons whose whole time is occupied in electrical occupations, the figure being exclusive of those persons who occupy only part of their time in electrical work. On many railways, for instance, the men in the signal cabin have to transmit electrical signals and occasionally whole telegraphic messages; but they have at the same time to attend to their signal levers and to the general working of the traffic. In various engineering works in England which have added an electrical branch to their previous business, the time of many employés is divided between the manufacture of electrical apparatus and that of other machinery. These persons are not included in the returns, and Mr. Graves estimates that if it had been possible to collect data relating to all those who are only partially occupied in electrical pursuits, the grand total of persons dependent for their employment on the various operations directly connected with electricity in these islands would amount to about 100,000, besides a very large addition to the numbers in various trades caused by the consumption of materials they produce. The employment of 100,000 persons means the support of at least 300,000. It is customary to reckon the average family maintained by industrial workers at 4½ to 5; but as in electrical work there is considerable preponderance of young and unmarried people, the average family has been taken as three per worker. On the same basis Mr. Graves estimates that throughout the world there must be about five millions of people who would have to seek for other means of subsistence if electricity and its commercial applications had not been made known to man.

A scrutiny of the figures in the little table given above is very interesting. We find that 56·3 per cent. of the total number of persons deriving their

Digitized by Google

subsistence from electrical occupations falls to the British land telegraphs. A material increase in this figure is not likely to occur in future, and it is rather probable that the percentage—if a similar return should be made in ten years' time—will be found lower. The reason is obvious. Telegraphy was the first practicable application of electricity, and has consequently had more time to be developed to its present high degree of perfection than other branches. The present net work of telegraph wires throughout these islands is practically complete, and a large accession of employés cannot be expected to result from the erection of the few new lines which are annually added to our telegraphs. An increase in the number employed might be looked for as a consequence of the more and more extended use of the telegraphs by the public; but the increase will not be very great, since improvements in apparatus are continually being made, whereby the speed of telegraphy and the work done by each operator on each wire are increased. In submarine cables there is for similar reasons no probability of a large increase in the number of persons employed; but when we come to the telephone, electric lighting, and to cable making, it seems highly probable that the absolute numbers, as well as the percentage numbers, of the above table will for some time to come continually increase. The telephone is not as yet used to anything like the extent commensurate with its great utility; and there can be little doubt that as soon as legal restrictions are removed by the lapsing of the various patents, an enormous expansion of telephone business will be the result. In electric lighting an expansion of business is also imminent. Patent rights and monopolies have in this case not had the same baneful influence as in telephones, but legal restrictions of another kind have hitherto hampered the general supply of electricity for lighting purposes; whilst the over speculation in electric light shares some six years ago has had the effect of deterring many from embarking money in this business. Hence the comparatively low number of persons engaged in electric lighting. The condition of this industry is, however, now on the point of a radical and salutary change, and we have little hesitation in predicting that by the end of the current year a fair number of central stations for the supply of electricity will be established throughout England. That the Electric Lighting Act of 1882 must be amended is admitted on all sides, and unless the time of Parliament is blocked by urgent political legislation, the coming session will probably see a new Electric Lighting Act, under which it will be possible for contractors to work, and which will secure capitalists a fair return for their investments. Meanwhile, electrical engineers have not been idle, but have improved the methods of generating currents and the various systems of distribution over long distances to a degree which will render the introduction of a public supply of electricity technically safe and commercially profitable. In estimating the possible increase in the number of persons employed in electric lighting, it must not be forgotten that the figures in the table include also those persons who are now engaged in the manufacture of electromotors and apparatus required for applications of electricity other than lighting. These applications at present form an insignificant part as compared with the lighting industry, but they cannot fail to develop largely within the next few years. As all these trades are dependent upon the production of cable makers, the latter will also find their business expand to a very large degree.

PATENT LITIGATION IN 1887.

MERITORIOUS inventors will be gratified with the retrospect of judicial decisions during the past year. A strong current of sympathy from the Bench in favour of inventors may be observed. This is especially so when the quantity of invention to support a patent claim has been seriously considered. Inventors cannot reasonably object to their Letters Patent being declared invalid where previous publications show their indentical manufacture or process. Previous knowledge often falls short of identity, but shows something very close to it. It not unfrequently happens that a very small detail in construction or variation in a process turns failure into success, and we propose to consider the amount of difference which the Courts have considered sufficient to support a patent during the past year.

To chemical inventors, a case of great importance is that of the Badische Aniline Company *v.* Levinstein (*Industries*, Vol. III., page 146). The invention was for the production of red and brown dyes. It was proved that there had been practically the same reaction with phenol instead of naphthol. The House of Lords decided that this did not destroy the novelty of the invention. In their judgment they referred to Dr. Griess' evidence, viz.: "In 1864, I distinctly state that by the combination of di-azo-benzol and phenol, dye was obtained, and if I had been a little cleverer, analogy would have induced me to prepare this very dye which is now under consideration. But analogy did not lead me to do that. Analogy does not go a long way in chemistry." Again, in Moseley *v.* The Victoria Rubber Company (*Industries*, Vol. II., page 465) the patent was upheld for the production of printed waterproofs. In that case the invention consisted of a combination of four or five processes, each individually old. The combination was new, and the article produced was new.

Turning from processes to mechanical inventions, the inventor will still find room for congratulation. In Wenham *v.* May the patent for the Wenham regenerative gas lamp was called in question. At the date of the patent superheating the gas or the air necessary for combustion, or both, was well known. Nevertheless, Mr. Wenham's improved gas lamp, consisting of an arrangement of parts whereby the heated air is conducted to both sides of the saucer-like frame, was justly considered worthy of patent rights. In Morgan *v.* Windover, the invention was for "improvements in carriages." The most serious allegation against the patent was want of novelty in the patented arrangement, because (1) it consisted in the application of a known article to an analogous and obvious purpose; (2) that purpose was one for which elliptic springs had been previously used; and (3) C springs, as used by the patentee, were mechanical equivalents of elliptic springs. Mr. Justice Kekewich overruled the objection, and held that "the method of application required the exercise of the inventive faculties."

In the action brought by the Haslam Foundry Company *v.* Hall (*Industries*, Vol. III., page 548) the difference between the plaintiff's invention and that of Windhausen of 1869 was a tap. Mr. Justice Stephen held that the insertion in an old set of pipes of a tap for the purpose of withdrawing moisture well known to be condensed there, and also known to be a source of inconvenience if not withdrawn, would form the subject of Letters Patent. The patent was, however, upset on other grounds, which saved Messrs. Hall the necessity of appealing. We would not wish inventors to place too much reliance on this case, but we mention it to show the tendency of the Bench. In Siddell *v.* Vickers the invention was for a mechanical appliance for manipulating forgings. It consisted of the usual wheel and endless chain, in which the forging is supported. On the inside of the wheel there are teeth. To the pin of the wheel there is loosely attached a lever. On the lever there is a pawl which engages in the teeth of the wheel. On raising the lever the wheel moves round, carrying with it the endless chain, which causes the forging to rotate. It was alleged that the Creuzot machine anticipated the invention. In the Creuzot machine the wheel was revolved by toothed wheels and telescopic shafting. The Judge held that Siddell's combination was a new one, and the new tool or appliance was a proper subject for Letters Patent. It might be here noticed that Siddell's appliance was considered simpler than the Creuzot, and improvements in machinery very often take the form of simplification. It often requires more inventive power to reduce the number of parts in a machine than to increase them.

In the following cases there were judgments in favour of the patentees: Proctor *v.* Bennis, Bray *v.* Gardner, Woodward *v.* Sansum & Co., Ellington *v.* Clark, Bunnett, and Co. Patentees' rights in electrical inventions have not had much consideration. The only litigation of note during the past year is perhaps that the Edison & Swan Company have upheld on appeal the very favourable decisions they obtained in the Court below. The time, however, is probably not far distant when the validity of the various dynamo patents will be tested. There have, of course, been cases unfavourable to patentees; they are, however, few in number. In the patent cases of the past year the judges seem to have taken the common sense view of inventions and inventors' rights. Inventors often ask whether some discovery of theirs forms valid subject matter of Letters Patent, but each case must necessarily stand on its own footing. Provided the identical manufacture or process has not been disclosed before, it might be well to test the patentability for themselves by the following considerations: (1) Has the invention increased production or lessened labour, or otherwise effected economy? (2) if so, has the machinery or process, on which it is an improvement, been long before the public? If these questions are answered in the affirmative, allegations "as to analogy," "as to invention being obvious," or being mechanical equivalents, may be disregarded. Results are, of course, a test of utility; but they may be also some test of novelty, and also of patentability. The results must, however, be traced home to and caused by the invention, and not merely have a concurrent history therewith.

COTTON SPINNING LIMITED COMPANIES.

WITHIN the past five months the cotton spinning industry has fortunately taken a turn for the better, and dividends have now become the rule rather than the exception. This satisfactory condition has not altogether been occasioned, as the newspaper reports generally state, by an improvement in the demand and higher prices for the yarn, but is due in a great measure to a gradual decline in the quotations of the raw material. This will be best understood from a consideration of the following statement: In July of last year the average quotation for middling Orleans cotton was 5⅞d. per pound, and for good fair Egyptian 7⅜d. per pound. During the month of December the prices for these cottons were respectively 5⅝d. and 6⅞d. per pound, or a difference in favour of spinners at the present time of ¼d. and ½d. per pound. In a factory using 30,000lb. of Orleans cotton weekly, this would show a saving of about £30 per week, or say £390 per quarter, a sum sufficient in itself to pay a dividend of 5 per cent. on the average modern mill share capital. It will thus be seen that a mill which six months ago could merely pay its way has now a considerable advantage for realising a profit in the purchase of cotton alone, providing that the sale of its product has been maintained at former rates. To determine this point it will be necessary for us to refer to the prices of yarn current at these periods, which may be found in the following table:—

Nos. of yarn.	Prices, July, 1887.	Prices, Dec., 1887.	Increase or Decrease.
32's cop (twist yarn)...	7 13/16d.	8 1/16d.	¼d. increase.
40's „ do. ...	8⅜d.	8⅝d.	¼d. do.
40's „ (weft yarn) ...	8 7/16d.	8 5/16d.	⅛d. decrease.
50's „ do. ...	9¼d.	9d.	¼d. do.

Twist yarns, it will be observed, have risen ¼d., but weft have receded a like amount, so that, speaking generally, prices are unaltered. To improvement in the yarn market, therefore, the present profits of our limited companies must not entirely be attributed. No doubt a brisker demand now exists than was experienced some months ago, but real legitimate means of realising a profit is still extremely meagre. Under the circumstances, therefore, prospective investors in limited company shares should hesitate before purchasing or risking their means, in the belief and hope that the present liberal dividends of 10 and 12 per cent. will be maintained. If cotton advances in price losses will again be the rule, and the advance which has taken place in the share quotations will rapidly be absorbed in a relapse.

In the management of the financial matters of Lancashire "limiteds" there is ample room for reform; under existing rules profits are often declared and dividends paid when really a loss should have been recorded. This fact we explained in a series of articles published in *Industries* during last year, (Vol. II., pages 395, 486, 506); and here again we are presented with another case in point, viz., the reduced price of cotton. If matters were properly adjusted in regard not only to the interests of the company, but also of prospective shareholders, and not for the advantage and profit of mere speculators, every farthing of the profit obtained from the fall in cotton should be placed to a reserve fund. What would be necessary to constitute a rise and fall might be determined in the following manner: An average price for each quality of cotton might be fixed each year by a committee of the Master Cotton Spinners' Association, so that when quotations fell below the stated standard the amount gained would be accounted for to the shareholders in the manner stated, and when an advance took place a sum equal to the difference would be taken from the special reserve fund to assist in maintaining the profit results at an approximate level. In examining the past balance sheets of one or two modern Lancashire companies, a very anomalistic series of results are shown. In one instance we find a concern recording a loss of £40 on the quarter's working, while for the succeeding three months a profit of £980 is stated to have been made. Under circumstances of this kind (which, by the way, are characteristic of the company) we might naturally expect that, after deducting the loss on the previous stocktaking, the directors would have recommended a distribution on a basis similar to the following: £500 say to a reserve fund,

Digitized by Google

and the remaining balance of £440 between the shareholders. Instead, however, of acting on this principle, £840 was distributed, and only £100 placed to future credit. This system, although radically bad, and most injurious to the interests of true investors and to the trade, is just what is desired by the speculator. It puts life into the share markets, and causes continuous fluctuations which would otherwise be avoided.

In looking over the published lists of the various companies, it will be observed that as a rule those concerns which have the least amount of share capital called up pay the largest dividends. This is due to the fact that they have all, without exception, large loan accounts on which from 3½ per cent. to 4 per cent. is paid, so that when trade is sufficiently good to admit of larger profits than this being realised in the working, the extra sums are added to the dividends of the shareholders. Other concerns, which have nearly or all of their share capital called up, are less fortunate. Their loan accounts are comparatively small, and as the security is not so great, 6 and even 7 per cent. has to be paid to the loanholders.

Letters to the Editor.

COLLAPSING PRESSURE OF IRON TUBES AND BOILER FLUES.

To the Editor of "Industries."

Sir,—There are probably many old boilers still in existence constructed at the time when exaggerated ideas as to the strength of their flues prevailed. These notions were modified when Sir W. Fairbairn published his formula for the resistance of flues to collapsing; but as this often gives results in excess, as it is incorrect in principle, and as there may be boilers working at pressures that are dangerous, I venture to submit a formula which I consider more accurate.

Let t=thickness of flue plates in sixteenths of an inch.
D=external diameter of flue in feet.

Then P the collapsing pressure in lbs. per square inch=$\frac{16t^2}{D^2}$

when the length of flue is seven times the diameter, or more. When the length is less than seven diameters the flue is stronger than one seven diameters long, in proportion as the length is reduced.

The collapsing pressure in a cold water test might be one-fourth more than that given by the formula, but not in the case of a boiler flue when the plates are heated, and there is an end pressure on the flue owing to its being expanded by the heat more than the shell. The least thickness of the plates, *i.e.*, the thinnest place, should be used as the thickness in the calculation; but if reckoned on the original thickness, it should be remembered that the flues of old boilers may collapse with two-thirds, or even one-half of the pressure given by the formula, depending on the wear and deterioration in quality of the plates, and on other defects. The flues are supposed to be plain, lap jointed and riveted, not flanged or fitted with rings, water pipes or stays.

Yours, &c.,
W. I. Ellis, M.Inst.C.E.

Manchester, 17th January, 1888.

THE FORTH BRIDGE.

The nineteenth quarterly report of inspection by Major-General Hutchinson, R.E., and Major Marindin, R.E., C.M.G., of the works in progress for the construction of the bridge over the River Forth, states that they are informed that the estimate made of the probable progress of the work has been maintained during the last quarter, and no serious interruptions have been caused by the weather; but the night shift has been discontinued for the winter, and the number of workmen employed has consequently been reduced. The greater proportion of the work in erection has been upon the internal viaduct and the top members of the piers and cantilevers, the bottom members having been carried out as far as is necessary for the present.

Temporary Works.

The additions to plant during the past quarter have been confined almost entirely to machines for the purposes of erection. The most important additions are four powerful and specially designed steam cranes, of which six in all will be required, and which, being attached to a frame work of girders forming a platform movable along the top members of the cantilevers, are used for the building out of these top members, and of the struts, and ties, and other portions of the structure within their reach.

Permanent Works.

South Queensferry.—*Main Piers:* That part of the superstructure over the piers which, including the internal viaduct, forms the central portion of the cantilever, is practically complete, the principal work remaining to be done being the riveting of some of the bracing and diagonal struts, and the fixing of the wind fence, and the whole of the flooring of the internal viaduct. On the southern portion of the cantilevers the bottom members are built out for 152ft. and riveted for 90ft., and the first bay of bracing between them is erected. The vertical webs of the booms of the top members, and the bracing between them, are erected for an average distance of 70ft. The first ties are built downwards a distance of 100ft. from the top junctions; the first struts are built to a level of 210ft. above O.D.; and the wind bracing between them is in place for 30ft. beyond the first intersection. The first vertical ties, with their bracing, and the support to the internal viaduct, are erected, and a length of about 100ft. of the girders and bracing of this internal viaduct is in place, and temporarily supported by wire ropes. On the northern portion the bottom members are built out for 160ft. and riveted for 103ft., and the wind bracing between them is erected to 15ft. beyond the second intersection. The vertical webs of the booms of the top members, and the bracing between them, are erected for an average distance of 60ft. The first ties are built down to the junction with the first struts, and the latter stand at a level of 220ft. above O.D., the first bay of the bracing between them being also in place. The first vertical ties, with their bracing, and the support to the internal viaduct, are erected, and a length of about 100ft. of the girders and bracing of this viaduct is in place, and supported temporarily by wire ropes. The riveted work at South Queensferry main pier now amounts to about 4880 tons, showing an addition of 866 tons during the quarter.

Cantilever and Viaduct Piers: The masonry of the cantilever pier has been raised, and now stands at a level of 150·50ft. above O.D. The girder viaduct piers are complete, and the end abutment and piers of the masonry viaduct are built to the level of the springing of the arches, 140·75ft. above O.D.

Inchgarvie.—*Main Piers:* The erection of the junctions at the tops of the vertical columns is in a very forward state. The vertical webs of the bottom booms, and the horizontal and vertical bracing of the top members, are erected, and the riveting of the former is complete. Some lengths of the webs of the top booms are also in place. Nearly the whole of the bracing between the vertical columns is erected and riveted, and the horizontal bracing for staying the columns at mid-height is complete. The internal viaduct over the piers is complete, with the exception of the wind fence and some flooring. On the southern portion of the cantilever, the bottom members are built out for an average distance of 150ft., and riveted for 137ft., and the first bay of bracing between them is in place as far as the intersection. The first struts stand at a level of 118ft. above O.D., and the first vertical ties at a level of 115ft. above O.D., and the girders and bracing of the internal viaduct are in place for about 100ft. On the northern portion, the bottom members are built for 152ft., and riveted for 120ft., and the first bay of the bracing between them is nearly all in place. The erecting platform has been raised to a level of 139ft. above O.D. The first struts stand at a level of 139ft., and the first vertical ties at a level of 155ft. above O.D. The girders and bracing of the internal viaduct are in place for about 100ft. The total amount of riveted steel work at Inchgarvie is 5817 tons, showing an addition of 1105 tons during the quarter.

North Queensferry.—*Main Piers:* The riveting of some of the bracing and diagonal struts, and the fixing of the wind fence on the internal viaduct, comprise practically all the work remaining to be done to complete that part of the superstructure over the piers forming the central portion of the cantilever. On the southern portion the bottom members are built out for 164ft. and riveted for 150ft., and the first bay of the bracing between them is riveted, and half of the second in place. The vertical webs and bracing of the top members are erected for a length of about 70ft. A length of about 150ft. of each of the first ties is built down from the top junctions; the first struts stand at a level of 212ft. above O.D., and the first bay of bracing is fixed. The erection of the first vertical ties, with their bracing, and of the support to the internal viaduct, is complete, and the girders and bracing of this viaduct are in place for a length of about 100ft. On the northern portion the bottom members are built out for 152ft., and riveted for 150ft., and the first bay of the bracing between them is riveted, and half of the second in place. The vertical webs and bracing of the top members are erected for a length of about 100ft. A length of about 95ft. of each of the first ties is built down from the top junctions; the first struts stand at a level of about 212ft. above O.D.; and the first bay of bracing is fixed. The amount of work completed on the first vertical ties, bracing, and internal viaduct is identical with that upon the same parts of the southern portion. The total quantity of riveted steel work at North Queensferry is about 5407 tons, showing an increase of 1112 tons during the quarter.

Cantilever and Viaduct Piers: The masonry of the cantilever pier now stands at an average height of 165ft. above O.D., and that of the viaduct piers and abutments is practically complete.

General Remarks.

Masonry and Concrete: Up to the present date about 566,500 cub. ft. of granite have been delivered, and 562,000 cub. ft. have been set; and about 111,600 cubic yards of rubble masonry and concrete work have been built.

Steel Work: In all about 46,740 tons of steel, an addition of 1578 tons since the date of the last report, have been delivered. The whole of the bottom junctions for bays No. 1 are practically completed in the yard. The fitting of all the bottom junctions for bays No. 2 is in hand, and the whole of the top junctions for bays No. 1 are well advanced. Good progress has been made with the fitting of the internal viaduct for bay No. 2 of the North Queensferry cantilevers, and the work on the bracing of the second bay of all the bottom members is nearly finished. The drilling of all the top members for bays No. 2, and the bottom members for bays No. 4, is nearly complete; that of struts No. 3 and ties No. 5 is about half done; and that of the top members for bays No. 4 is commenced. The whole of the bottom booms and two-thirds of the top booms of the second bays of the internal viaduct are complete. During the quarter the weather on an average was bad for half the time, and from fair to good for the other half. The greatest wind pressures recorded were 11lb. per square foot on the large gauge, and 20lb. on the small gauge, on Inchgarvie, on the 25th November; 24lb. on the small gauge, on the North Queensferry cantilever platform, on the 2nd November; and 32lb. on the small gauge on the top member at South Queensferry, on the 22nd November. The average number of men employed per diem during the quarter has been 3790, and the number employed on the 28th November 3370. The quality of the work continues, so far as we are able to judge, to be excellent. There have been eight fatal accidents among the workmen during the past quarter, two having been killed during a gale of wind by a plank blown for some distance from the North Queensferry pier. It is stated that none of the accidents were due to any failure of plant, such as has caused accidents in previous quarters. Since the last visit of the inspectors very considerable additions had been made to the appliances for the protection of the men employed upon all parts of the structure. It is stated that it is very difficult to persuade many of the men to adopt the most ordinary precautions, and the inspectors mention that they noticed more than one instance of what can only be characterised as foolhardiness, such as should be discountenanced and prevented in every possible way.

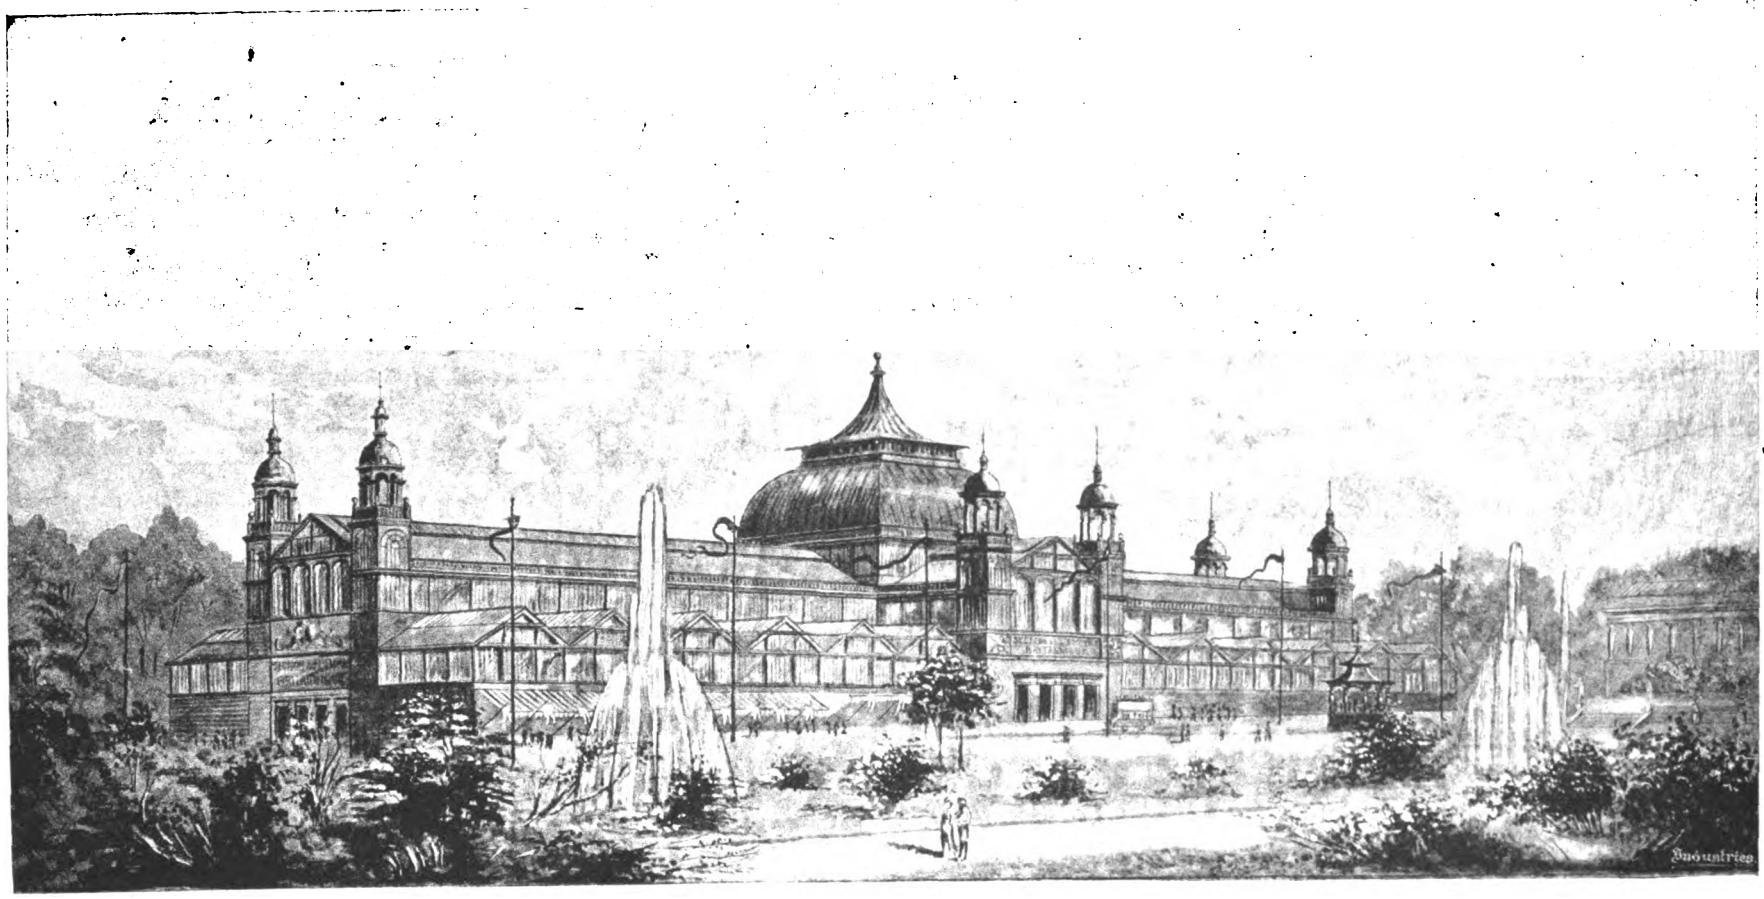
Reviews.



Cours de Construction Navale, professé a l'ecole d' application du Génie Maritime. Par A. Hauser, Sous-Directeur a l'ecole d'application du Génie Maritime. Paris: E. Bernard et Cie. 1886.

We have already given (*Industries*, Vol. I., page 447) a preliminary notice of the course of instruction in marine engineering in "L'ecole d'application du Génie Maritime," in course of publication, and we now wish to direct the attention of our readers to that in naval construction, by M. Hauser, the sub-director of the school. It is without doubt one of the most complete treatises of the kind in existence, consisting as it does of one large volume of 590 pages of text, and another of 340 plates illustrating that text, and although the book is intended chiefly for the use of students in the French dockyards, it is deserving of study by students of naval architecture in this country, especially those connected with the Admiralty. France, Germany, and Italy, among continental countries, are ever ready to appropriate any improvements we make in naval architecture, and our shipbuilders must keep their eyes open as to what is being done by our neighbours. In France the scientific study of naval architecture is of much longer standing than in Britain, and there can be no doubt that we owe many of its most important developments to the researches of French mathematicians and physicists. During the last century, and the beginning of this one, the ships captured from the French served as models for the English Admiralty officials, a practice which ceased only when arrangements had been made in this country for affording those officials a scientific training of a similar nature to that which had long been given in France. The French ships excelled in gracefulness of form, and consequently in speed, while those of Britain were better built and better manned. We owed our victories, however, more to the fighting qualities of our sailors than to the superiority of our ships. Constructive officers had no means of professional instruction, except such as were of a practical nature, until 1811, when the Royal Naval College for the education of apprentices was instituted in Portsmouth dockyard. On another occasion we may trace the development of instruction in scientific naval architecture in Britain; suffice it now to say that the combination of an intelligent knowledge of principles with the superior workmanship of our dockyards, produced excellent results, and the French soon recognised

BRITISH EMPIRE SECTION.

the inferiority of their ships in sailing, and the frequency of their sustaining damage as compared with those of the British. In 1832 a commission was appointed by the French Minister of Marine to inquire into the causes of this inferiority, and advantage was taken of the union of squadrons of British and French ships of war in the Downs, to observe their relative performances and the conditions affecting them. A most interesting report followed.

The course of naval construction in the book under consideration is divided into eight parts, viz.: (1) General explanations, (2) Construction in wood, (3) Construction in iron, (4) Launching, repairs, &c., (5) Fittings of the hull, (6) Accommodation on board, (7) Masting, sails, and rigging, (8) A description of the principal types of ships of war. The first two may be passed over without special notice, except perhaps the remark that the second is unnecessarily long for a modern treatise. Wooden ship building in this country and in France has now almost died out, and fifteen chapters form too great a space to give to it in a modern treatise. The part on construction in iron and steel is excellent. Interesting historical details are given of the introduction of these materials for ship building, and their advantages and disadvantages are duly noted. Some points, however, are not so complete as they might be, but we suppose that these are given in the lectures in the school of which this book presents an outline. A very short *résumé* is given of the rules of Lloyd's Registry and the Bureau Veritas, and occasional reference is made to their application; but as the author treats chiefly of ships of war, sufficient details are not given to make his remarks of much use to builders of merchant ships, although the methods of construction of ships of war are very fully explained. The chapter on riveting is very complete and valuable, and enters fully into the practice both in France and England, as well as the calculations for the various proportions, and the author strongly advocates the use of mechanical methods when possible, while that on plating and armour contains a vast amount of useful information. The part relating to the use of steel might have been made more complete by the incorporation of the results of some of the experiments which have been made in this country and in France. This section is concluded by chapters on composite construction, on water tight compartments, and on ventilation, which, however, are somewhat fragmentary in their nature. The section on launching and appliances for the repair of ships will be read with interest by British ship builders, as it contains descriptions of methods which seem to be peculiar to France, and of the apparatus employed, while the accounts of the different kinds of docks, basins, &c., will be found useful, although we must admit that some parts are a little antiquated. We need not enter into details of the sections relating to the fittings of the hull, the accommodation on board, and masting, sails, and rigging; they are all very complete, and deserve careful study from Admiralty officials, as they give much information which is not generally available.

The eighth and concluding section on the principal types of ships of war is the one which will be read with most interest by non-professionals, and possibly also by statesmen, as it gives in a very small space a *résumé* of the navies of the chief powers, special attention, of course, being paid to that of France. It begins by stating the constitution and programme of the latter, and its chief functions in times of peace and war. In time of peace, it has for its object to support diplomatic demands by military demonstrations, to protect and keep the colonies in relation with the mother country, to assure the safety of the merchant navy and to repress all acts of piracy, and, lastly, in foreign countries it ought to intervene to cause the rights of French citizens to be respected. In time of war, the fleet is intended to overcome and reduce the enemy; in the case of offensive action, an attack is made upon the fortified places in the territory of the enemy, by bombardment, and, if necessary, by disembarking an army corps. If, on the other hand, the enemy do not wait for the attack, and bring their fleet to the assailants, it is necessary to have ships analogous to those of a besieging fleet, but endowed with greater mobility. Should the enemy be victorious, and carry the theatre of war to the shores of the assailants, it is necessary to defend them, in addition to the fortifications situated upon the most important points on the land, by coast-guard ships and by torpedoes. Lastly, a large number of small ships are required for various purposes, such as acting as coast police, for the protection of fishermen, and the service of the arsenals. Subject to these uses the French fleet has been arranged in classes, and descriptions of examples of each of those are given by the author, and a comparison made with similar ships in foreign navies, which will no doubt be carefully studied by our Admiralty officials and others interested in the subject. On the whole we think the book a valuable production. It covers a very wide field, and cannot, of course, enter into full details of all the subjects mentioned, nor, perhaps, is it intended that it should do so, being rather an outline of the course professed in the school; but we must say it is one of the most complete outlines in existence, and its concluding sentence may be quoted, to show the sentiments which are engrafted in the young French engineers. It says: "L'ingénieur ne pourra donc que chercher à satisfaire à des nécessites toujours changeantes, à des programmes sans cesse modifiés par les progrès de l'art militaire, les perfectionnements industriels, les transformations politiques. Chaque jour, il devra fournir l'instrument de combat nécessaire au marin, qui lui en suggère les principales données, souvent difficiles à concilier. C'est ainsi qu'il pourra, pour sa part, 'contribuer à la gloire des armes de la France, et soutenir l'honneur du pavillon.'"

THE BRUSSELS EXHIBITION, 1888.

BRITISH EMPIRE SECTION.

We have already, in our impression for the 4th November last, given a bird's-eye view and general plan of this Exhibition, and we now are enabled, through the courtesy of the architects, Messrs. Maxwell and Tuke, Princess-street, Manchester, to give above a general view of the main building, which will contain the exhibits belonging to the British Empire Section. The entire area allotted to the whole exhibition comprises about 316,000 square metres, and of this space 20,000 square metres have been set apart for the British section. The building we now illustrate is being constructed under the superintendence and direction of Messrs. Maxwell & Tuke, and Mr. Byron, an English contractor, and will, to a great extent, consist of part of the buildings erected for the late Royal Jubilee Exhibition held at Manchester last year. The nave will be identical with the nave of that exhibition, and will be about 500m. long, with a transept and towers forming the central entrance. The building will be connected by a gallery with the main building of the general exhibition, but in all other respects it will be a complete exhibition in itself. As we have before stated, the general management of the British section has been entrusted to the manager of the late Manchester Exhibition, Mr. S. Lee Bapty, who has been appointed with the sanction of the Belgian Government and the Chief Commissioner of the British section. Judging from the success which followed his management at Manchester, we have good reason to anticipate a favourable result for the British Empire Section at the forthcoming Brussels Exhibition.

SWINTON'S SYSTEM OF DIRECT TELEPHONIC EXCHANGE.

Up to the present, whenever the number of telephones connected to the circuit exceeded two or three, it has been usual to make the connection by means of a central exchange, from which radiate the wires to the subscribers, and for town telephony this no doubt is the only practical system; but when telephonic communication is required within the limits of a building, or even those of a works, the central exchange system does not offer sufficient advantages to compensate for the cost of keeping an attendant at the exchange, and to provide for such cases Mr. Swinton has devised a very ingenious system of intercommunication between a limited number of instruments

Fig. 2.

without making use of an exchange centre at all. In this case each instrument or station (we must not say subscriber, for virtually the instruments are all in the service of the same concern) can call up any of the other stations without interfering with the rest, notwithstanding the fact that at the same time conversation may be going on between two other stations on the circuit. We had last week an opportunity of testing this system in a warehouse in London, where six instruments are fitted in various floors and offices. In this case the telephones have been installed in lieu of speaking tubes. It is evident that to produce intercommunication between six speaking tube stations, there would be required fifteen separate tubes, whereas the communication between six telephone stations requires only eight separate wires. These wires are bunched together into a small and flexible cable, thus occupying very much less space than fifteen speaking tubes. The time for a call is not longer with the telephone than with the speaking tube, whilst the clearness of speech is very much greater. The arrangement of the circuit will be understood from our illustration (Fig. 1), whilst Fig. 2 shows the instrument at each station. It consists of an ordinary Swinton telephone, with the addition of a switch box below. When the telephone receiver hangs on the switch hook, as in our illustration, the call bell is in circuit with the two contacts of the jack plug, which is usually inserted into the hole at the extreme left of the switch box, and in this condition the instrument is ready to be called up by any other station on the circuit, as will presently be explained. When the telephone receiver is taken off the hook, it is automatically switched into circuit and the call bell switched out of circuit in the usual way. The front of the switch box is fitted with plug holes distinctly lettered with the names of the different telephone stations comprised in the system.

SWINTON'S DIRECT TELEPHONIC EXCHANGE.

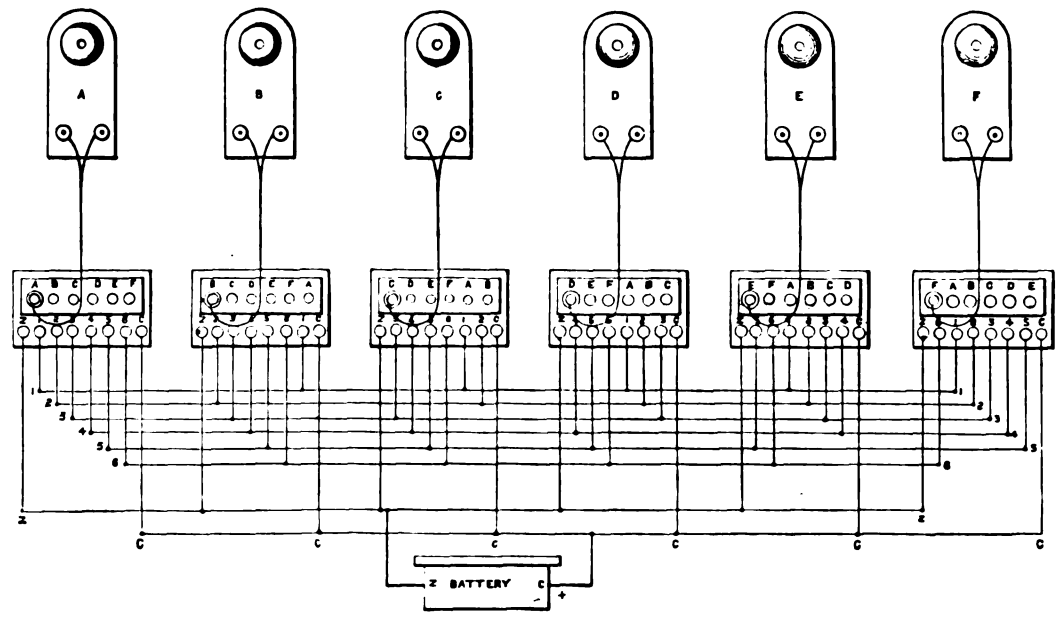

Fig. 1.

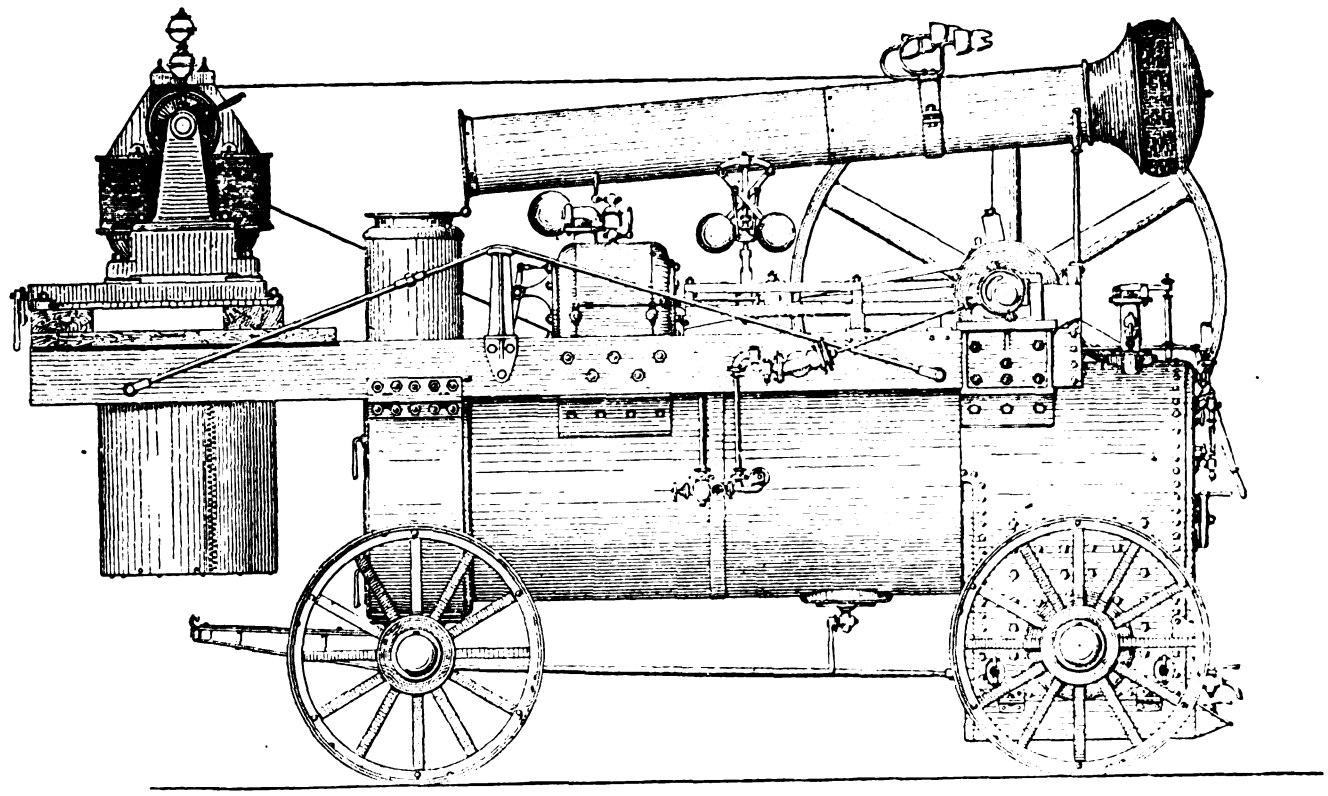
In connection with the terminals of the telephone is a flexible cord terminating in the jack plug already mentioned, which simply consists of two metal strips separated by a piece of insulation. This can be inserted into any of the holes in the switch box for calling up the station indicated by the letter on the box. Referring to Fig. 1, it will be seen that there is only one battery (in the warehouse we inspected, where there are six stations, the battery consists of eight Leclanché cells, No. 2), and all the switch boxes are coupled in parallel, the terminals for the battery connection being marked Z and C. The other connections between the stations are clearly shown on the diagram.

To explain the working of the system, let us assume that A wishes to call up C. He would first take off his telephone from the hook, then draw out the plug from A and insert it into the hole marked C, by which means the call bell of C would begin to ring, the ringing of the bell being notified to A by a loud rattling noise in his own telephone receiver, due to the current from the battery being rendered intermittent by the contact breaker of the bell at C. Upon C removing his receiver from the hook the noise ceases, and A knows that he can talk to C, and *vice versâ*. The current now goes from the positive pole of the battery through the receiver and transmitter of C, through its plug C, to line No. 3 into the plug C of the instrument A, then through its receiver and transmitter and back by Z to the negative pole of the battery. When the conversation is completed A must replace his plug in the A hole of his switch box, so that other stations may be able to call him up if required. It is evident from an inspection of the diagram that any two stations may communicate with each other, irrespective of communication going on between any other two stations; but if B tries to call up A or C whilst these two are in communication, the absence of the rattling noise in his own receiver intimates to him that the line is engaged. This prevents the interruption of conversation, and any possibility of confusion. If any station does not wish to be called up, as might be the case where the instrument is fixed in the principal's room, who only requires to initiate communication with the other stations, but not to be called up himself, all he has to do is to omit inserting the plug A in the first hole of the switch board. All these instruments are worked with a direct battery current, and have no induction coils; but for long distances Mr. Swinton has just brought out a modification of his original instrument, in which induction currents are employed; but instead of using a separate induction coil to each transmitter, he uses the receiver of each instrument as the induction coil for the transmitter of the same instrument. The telephone receiver contains a soft iron core, which becomes magnetised by the battery current traversing the primary coil as soon as the receiver is taken off the hook. On the same core is a fine wire coil connected to the line. The transmitter is in series with the primary coil of the receiver, and the induced current of the secondary coil goes to actuate the receiver of the other station. These instruments are made by the Equitable Telephone Association, Limited, of 75, Queen Victoria-street, E.C.



PORTABLE ELECTRIC LIGHT PLANT.

A few weeks ago our Vienna correspondent referred to some successful trials with a portable electric light plant on the North-Western Railway of Austria. The details of this plant, which has been constructed by Messrs. Siemens & Halske, of Vienna, have now been communicated by Herr Friedrich Bechtold to the Journal of the Vienna Society of Electricians, from which we reproduce the illustrations on the next page. It consists of a portable engine, on which is mounted a dynamo, and of one van containing all the accessories. The railway company stipulated that the vehicles should be adapted for travelling over common roads, and that an apparatus should be supplied by which they could be loaded or unloaded from railway trucks on either side. This apparatus consists of an inclined frame placed at one end of the truck, and a winch placed at the other end. The vehicle (engine or van) is drawn up on to the track, or let down from it by means of the winch and a rope. The company also stipulated that the dynamo should be able to supply eight 9 ampère arc lamps, and six 16 c.p. glow lamps simultaneously, and that the arc lamps should be burned in parallel series of two, and the incandescent lamps all in series; this condition being imposed so as to have the lamps as nearly as possible independent of each other. The engine is an ordinary portable engine of 12 effective horse power, running at 175 revolutions per minute, and driving the dynamo direct from the fly wheel by a belt. The engine is placed on the top of the boiler in the usual way, and on a prolongation of its frame, consisting of two stout oak beams, is fixed the dynamo, a sliding bed and screw serving to tighten the belt. The cylindrical casing below the dynamo is a water butt, which is detached and placed by the side of the engine when the latter is at work. A light roof, supported on iron poles, is fixed over the engine so as to keep the dynamo from getting wet in bad weather. This roof is carried on the top of the van when travelling. To protect the dynamo from the heat of the chimney the lower part of it is surrounded by an asbestos mantle. The dynamo is compound wound for 110 volts, and a maximum output of 50 ampères, the speed being 1100 revolutions per minute. The total weight of the engine and dynamo in travelling condition is 6 tons 6cwt. The cart weighs with all accessories 3 tons 16cwt., and contains the following: On the roof there are eight bamboo masts 21ft. long for the support of the arc lamps, and thirty bamboo rods 18ft. long for the support of the cables. To each side of the cart is attached one half of a telescopic ladder 20ft. long. The other tackle required is stowed away in the interior of the cart, as shown in our illustration, and consists of eight arc lamps occupying the central space, and of which only one is shown; eight reels of insulated cables, six containing 380 yards each, and two 540 yards each; a switch board for five circuits, with current and potential indicators and rheostats; six glow lamps with fittings, a number of double bell insulators, brackets, couplings, reserve carbons, reserve brushes, a vice, a complete set of lineman's tools, a small set of engineer's tools, several coils of wire, two water buckets, and three coal baskets. Under the seat

Constructed by Messrs. Siemens & Halske, Electrical Engineers, Vienna.

Portable Engine and Dynamo.

Section of Van containing Necessary Appliances.

of the driver are stowed away the cast iron foundation plates and sockets for the masts of the arc lamps, and a number of wedge-shaped steel spikes to serve as earth anchors for the guy ropes of the masts. All the circuits are numbered, so that no mistake can be made in the connection between the lamps, cables, the dynamo, and the switch board. On the first trial of this plant, the time occupied from unloading until the whole of the five circuits were in working order was nine hours, and the work was performed by twelve unskilled labourers. On a second trial, when only two arc lights and the six glow lamps were used, the work was performed within five hours by six labourers. This plant will probably have an extended use, especially as its management can be entrusted to unskilled labour.

THE BERNSTEIN SYSTEM OF ELECTRIC LIGHTING.

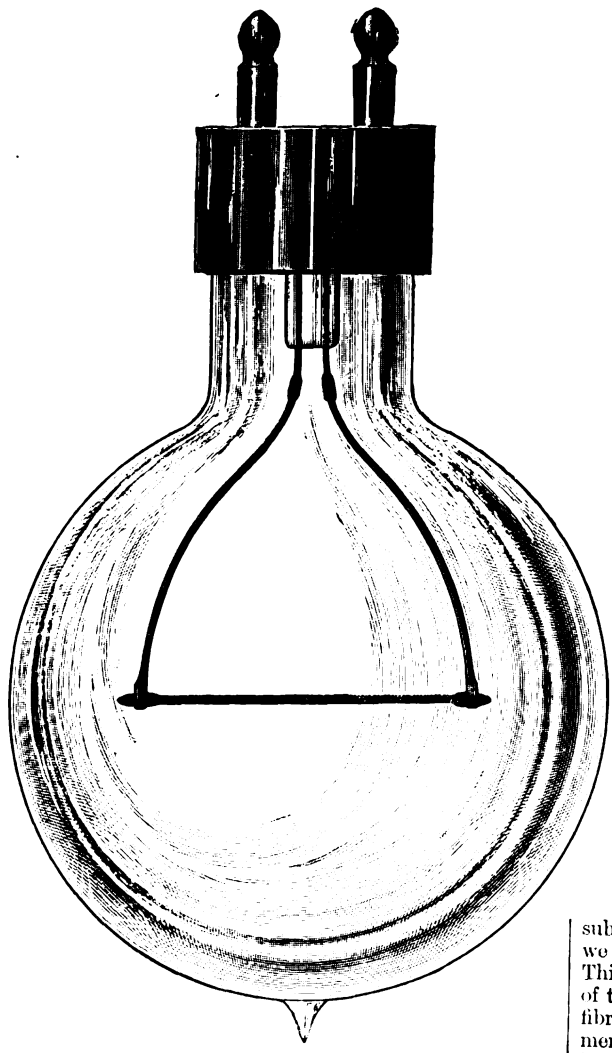

FIG. 1.

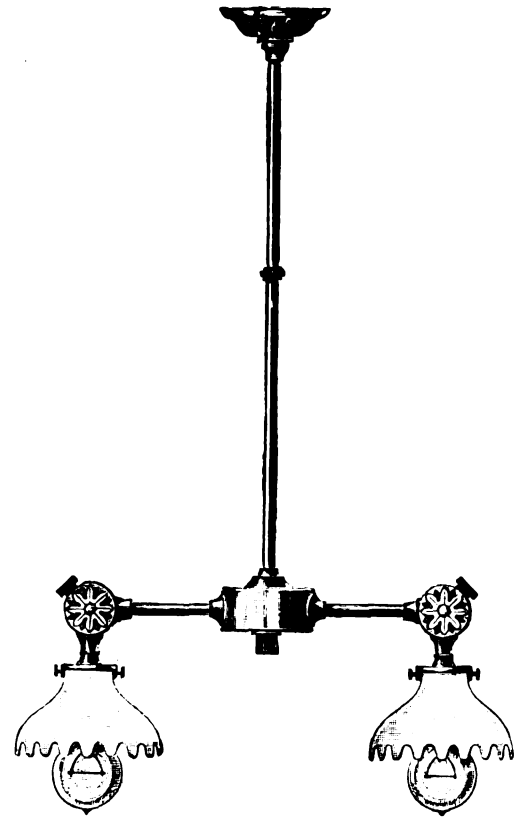

FIG. 2.

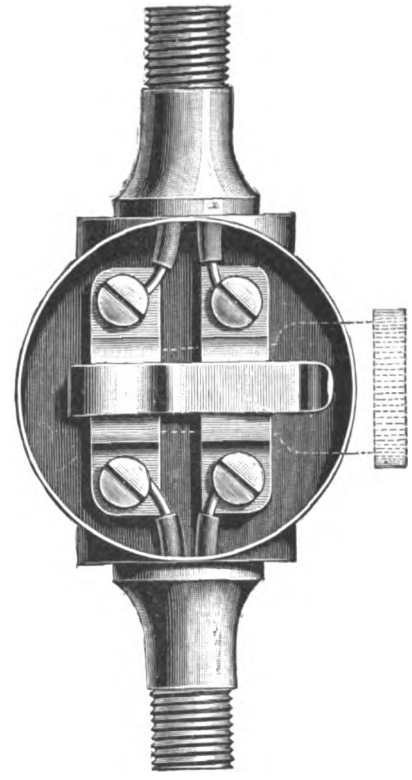

FIG. 3.

THE BERNSTEIN SYSTEM OF ELECTRIC LIGHTING.

MR. BERNSTEIN has for some years been advocating the series system of electric lighting by glow lamps of low resistance, and a number of installations, especially in factories and mills, has been fitted up on this plan. As early as 1883 Mr. Bernstein showed his system at the Vienna Exhibition, but since then he has made considerable improvements in its various details. In principle, the series system has some advantages over the parallel system. In the former it is possible to employ comparatively thick filaments in the lamps, and the result is greater economy than with high resistance lamps. Why thick filaments should admit of being worked at a higher efficiency than thin filaments, and yet last quite as long, has not yet been satisfactorily explained; but it is nevertheless generally admitted to be a fact. On the other hand, if we work both filaments at the same efficiency, the life of the stout filament will be longer than that of the thin filament. Another advantage of the series system is the possibility of keeping the light emitted by each lamp absolutely constant, notwithstanding variations in the total number of lamps supplied from the circuit. In parallel distribution this condition can only be obtained approximately, since the conductors must have a certain resistance, and the loss of potential must, to a certain extent, vary with variations in the consumption of current. In the series system, on the other hand, as long as we keep the current absolutely constant, the light emitted by each lamp must also be constant, whatever the resistance of the leads may be. To provide against the extinction of all the lamps in case of the breakage of one, Mr. Bernstein devised, about two and a half years ago, an electromagnetic arrangement to be added to each lamp, which automatically shifts the current from the lamp to a by-pass in case of the lamp failing; and it is interesting to note that at the last meeting of the Berlin Society of Electricians, Mr. William Siemens brought the subject of series glow lighting before the Society, and showed, as the latest practice of Messrs. Siemens & Halske, an electromagnetic device in principle similar to that of Mr. Bernstein. The latter gentleman, however, very shortly after designing it, abandoned this magnetic by-pass, and substituted a very simple and ingenious fusible plug, which we described in our impression of the 7th January, 1887. This plug is inserted as a shunt to the lamp, and consists of two conducting portions, insulated from each other by fibre strips, and a small quantity of a mixture of oxide of mercury and powdered carbon or graphite. This mixture is a very bad conductor when the e.m.f. is only that occurring between the terminals of the lamp; but upon the lamp failing, the e.m.f. rises to a sufficient degree to electrolyse the paste of oxide of mercury and graphite, forming metallic mercury, and thus establishing the by-pass. To insure greater safety of contact, the centre piece of the plug, which formerly was fixed, has now been provided with a spring, as shown in Fig. 4. When the paste is reduced, and thus shrinks, the spring causes the centre piece to follow into the cup of the lower portion of the plug, making the contact perfect. The plug boxes have also been improved over last year's pattern, and are illustrated in Figs. 3 and 6. In the style shown in Fig. 3 the plug box forms a part of the bracket to which the

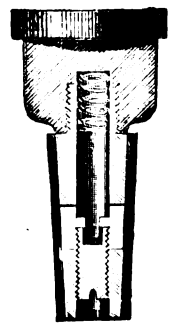

FIG. 4.

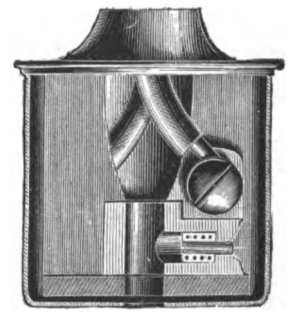

FIG. 5.

lamp is attached, the ends being screwed to the usual gas thread employed in such fittings. The wires pass through the interior of the tube, and are attached to two metal strips, across which rests a metal spring when the plug is not inserted. In this condition, therefore, the plug box simply short circuits the main leads. When the plug is inserted the insulating part at its upper end raises the spring out of contact with one of the strips, and thus forces the current to pass through the lamp. Should, however, the lamp break, or the plug be inserted when the attendant has forgotten to place a lamp in the fitting, the whole potential difference of the dynamo will, for the moment, come between the lower and upper portion of the plug, electrolysing the plate, and thus short circuiting the mains. Should the plug be withdrawn before a new lamp is fitted no danger to the circuit or to the attendant can arise, because the top spring simply comes down and again short circuits the connections, so that in this most recent design Mr. Bernstein has provided for all possible contingencies. The plug box, shown in Fig. 6, is intended for use on the mains, as they are encased in wooden bearings on the wall, and the illustration is so clear that no further description is required.

Coming now to the lamp (Fig. 1), it will be noticed that Mr. Bernstein has abandoned the two-pole type which he originally employed, and now introduces both

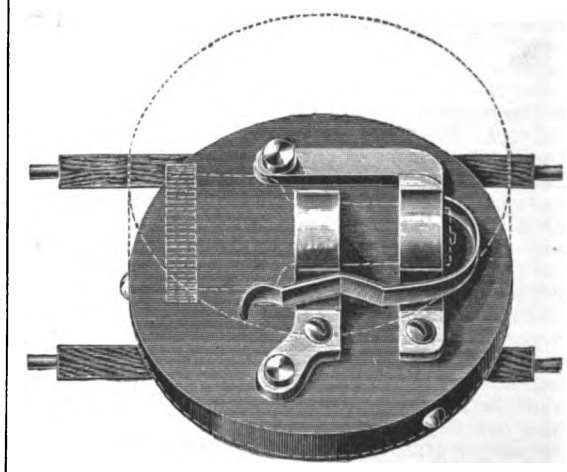

FIG. 6.

wires at the same end of the globe. The filament is a straight rod of carbon attached to the ends of two copper strips, as shown in our illustration. The leading in wires are of platinum fused into the glass, and connected with two stout brass terminals, shaped as shown. The lamp holder (Fig. 5) has been specially designed to carry the large current of 10 ampères without heating of contacts. The brass terminals of the lamp fit into corresponding holes in gun metal contact pieces supported on fibre, and the terminals are locked in position by means of cross pieces pushed into the nick of each terminal by a spring. One of these terminals is shown in section in our illustration. With this improvement in the construction of the lamp the latter is rendered more easily applicable to decorative fittings; and on a recent visit to the Bernstein Company's works in Commercial Road, London, S.W., we

Digitized by Google

saw a large number of very handsome and artistic fittings adapted for the Bernstein lamp. We select for illustration in Fig. 2 one of these, being a two-light pendant. The mains are brought down inside the pendant into a circular box in which is situated the switch; from there they pass through the horizontal arms and plug boxes at the corners down to the lamps. The switch has four poles, and consists of an insulated base, on which are fixed four metal segments of a circle. Two of these, side by side, are connected to the mains, and the other two to the lamp wires. Connection is made between these segments by means of two phosphor-bronze springs attached to the face of a second insulating disc, to which is also fixed the switch handle. In one position the springs establish connection between the main wires and lamp wires, and when turned through 90° one spring short circuits the main wires, whilst the other short circuits the lamp wires. The switch is absolutely sparkless, as can readily be gathered from the above description of the connections; and it has this further advantage, that when the current is switched off the lamp, both lamp wires are completely disconnected from the main wires, and any part of the lamp wires, or of the fitting, may be touched when adding or repairing a fitting without danger, even if a leak to earth should exist on the main circuit.

Mr. Bernstein proposes to use his system not only for isolated plants but also for central station lighting. The dynamos employed would all be designed to give a current of 10 ampères, at a maximum pressure of from 1000 to 2000 volts. Each dynamo is to be driven by belt from its own steam engine, and constancy of current would be insured by electric regulators, varying the speed of the engine in accordance with the number of lamps in circuit. Under these conditions the e.m.f. will be very nearly proportional to the speed of the engine, and as the current is constant, an ordinary speed counter on the engine shaft could be used to show the number of Board of Trade units supplied by the dynamo within any given time. The street mains would consist of No. 10 wires or equivalent cables, insulated from each other, and a number of these would be drawn into iron pipes laid underground along the streets. Each circuit would be tapped by house wires, and supply current to such a number of lamps in series as corresponds to the maximum pressure available at the station.

THE WELSH GOLD FIELD.

At a meeting of the Geologists' Association, held at University College, London, the 6th inst., a paper on the above subject was read by Mr. T. A. Readwin. The first referred to the history of the gold field, which had been known to geologists for nearly fifty years. While previously it had yielded to the ancient Britons the metal for the ornaments they so extravagantly used, its fame may also have been one of the inducements to the Roman invasion, as the invaders certainly mined gold in the neighbourhood. In the seventeenth century still more important operations were carried on by Thomas Bushell, who rented the mines from Charles I., and erected a mint at Aberystwyth. One of the £3 pieces then coined was exhibited. Between 1631 and 1645 gold to the value of quite two millions of our money was obtained. The author then summarised the literature of the subject since a paper read by Dean before the British Association, in 1844, again called attention to the matter. Amongst these were papers by Calvert, Sir A. Ramsay, J. A. Phillips, Sir W. W. Smyth, Forbes, Ansted, and a series by Mr. Readwin. The gold field which is now attracting especial attention occupies from 50 to 60 square miles of the mountainous district of Merionethshire, on the north bank of the river Mawddach. Its geology has been well described by Sir A. Ramsay (*Quarterly Journal of Geological Soc., Vol. X.*), who has shown that it consists of slates and flags—the Lingula flags—resting upon the Aberystwyth grits, the whole penetrated by many quartz veins and dykes. The gold mainly occurs in the veins near the junction of the Lingula flags and the underlying grits, especially in the neighbourhood of the greenstone dykes. It occurs associated with other minerals, such as ores of copper, silver, lead, and zinc, with mispickel, micà, barytes, witherik, and sometimes traces of platinum. There are hundreds of such lodes, from a few inches to 46ft. in thickness, all more or less auriferous. He had himself had over 1600 assays made, including some by Johnson, Matthey, & Co., and only 14 gave no trace of gold; 140 gave under 3dwts. of gold per ton, 48 gave 3dwts. and under 5dwts., 133 gave from 5dwts. to 10dwts., 64 from 10dwts. to 3oz., 40 from 10oz. to 20oz., 22 from 20oz. to 50oz., 15 from 50oz. to 100oz., 11 from 100oz. to 200oz., 2 from 500oz. to 1000oz., 1 between 1000oz. and 2000oz., 3 between 2000oz. and 5000oz., 5 between 5000oz. and 10,000oz., and finally one gave between 10,000oz. and 20,000oz. He had experimented on the Gwynfynydd lode stuff, and between 1882 and 1884 had extracted 44oz. 10½dwts. of gold from 53¼ tons of the ore by 22 assays; of these 3 yielded under 5dwts. of gold to the ton, 6 between 5dwts. and 10dwts., 6 between 10dwts. and 1oz., 1 between 2oz. and 3oz., 1 between 5oz. and 10oz., 2 between 10oz. and 20oz., 3 between 50oz. and 100oz., 1 yielded 22,000oz., and one as much as 35,840oz. per ton. He had, however, made further assays of the ore from this mine, with a total result of 113½oz. of gold from 72 tons, obtained by 78 distinct trials, being at the rate of 1oz. 11dwts. 13gr. to the ton. He enumerated twenty Welsh mines that had yielded gold, including the Cwmeisen, Dolfrwynog, Tyddyn, Gwladys, Glasdyr, and the Vigra and Clogau. From the last alone 16,468oz. 18dwts. 3gr. of gold had been obtained, and sold mostly to the Bank of England for £62,849. 0s. 6d., one-twelfth of which went to the Crown as royalty. In conclusion, Mr. Readwin regretted the exaggerated anticipations now current as to the future of this gold field, and expressed the caution that not more than half an ounce—or at most 1oz.—of gold to the ton should be expected; he had published that opinion twenty years ago, and still adhered to it. He entertained most sanguine hopes, however, that the district would become a valuable and prosperous mining centre.

A discussion followed, in which Dr. Hyde Clarke, Mr. Topley, Dr. Hicks, and others took part. Professor Blake and Dr. Edwin Ball urged caution in dealing with the subject, the latter pointing out that the gold occurs there in pockets, a condition most unfavourable to profitable mining. A vote of thanks to the author closed the proceedings.

THE COPPER "BOOM" AND COPPER MINING.

We have already directed attention to the crippling effects of the present prices of copper on those industries which consume the metal largely, and expressed an opinion unfavourable to the "ring" of speculators who have brought such prices about by that indefensible method of dealing known as "cornering." It is being urged with some warmth by certain journals that there is another side to the question, that there are producers as well as consumers, and that the former deserve as much consideration as the latter. Doubtless there is some truth in this contention; and if the language in which it is couched did not imply that the present rates are necessary to the well being of the copper mining industry, we should have nothing to say against it. But it requires considerable power of self control to follow patiently the course of an argument tending to show that the rise from £39. 15s. to £85 a ton in less than two months is justifiable and generally beneficial to industry. No doubt the low level of £40 was remunerative only to those mines which could produce cheaply; but it is an undeniable fact that such mines exist, and that their output was sufficient for the contracted consumption of a few years back. It is, moreover, equally undeniable that these low prices led to a largely increased consumption of copper. This larger consumption was beneficial to producers and consumers alike. All that was needed, then, was a sufficient rise in price to enable the best of the more costly mines to add their production to meet the constantly growing demand, without seriously restricting the use of the metal. This much probably will be readily admitted. The differences of opinion come when we attempt to fix a limit to the rise. But there should be little divergence at this point. The problem is simple enough, and its solution is obvious. It is well known that plenty of copper may be produced remuneratively, from the mines now being worked, at £50 a ton. This is a fair price for copper, sufficient for the producer, without being burdensome to the consumer. At £80, copper becomes useless for many purposes. It is thus abundantly clear that present prices, and even a considerably lower level, must lead to a very serious restriction of its use. This effect will begin to operate at once, and that alone would suffice to bring back the price to £50 in a little time. But the high profits now obtainable will lead, on the other hand, to a greatly increased production. Every mine will be worked to its utmost capacity, and what is of more serious consequence, numerous properties, which in the ordinary circumstances of trade cannot be profitably worked at all, will be again set in operation. We need no prescient intelligence to show us that in a very short time the market must be glutted with copper, and that instead of the profitable £50, the metal will be a drug at £40. Where, then, will be the benefit accruing to the copper mining industry from the better conditions of trade generally and the upward movement initiated by the syndicate? Had the latter been content with a rise of 20 per cent., genuine shareholders of copper mines might have had something to be thankful for, even to that self seeking body of speculators. As it is, they are preparing for themselves another long period of adversity as a set-off to a spurt of at best a few months' duration.

SMOKE ABATEMENT.*

The author said it was not his intention to bring forward any new method of treatment, but rather to lay before the members a few of the evils caused by black smoke, the Acts of Parliament in force in the city of Glasgow and neighbourhood for the suppression of the smoke nuisance, the methods of carrying out the provisions of these Acts, and shortly to mention a few of the methods which had been advocated for the total abolition of smoke in our towns and cities. To show that the smoke nuisance was not confined to the present day, he quoted from the author of "Sylvia," who in 1661 describes coal smoke as the cause of every evil and the herald of the approaching destruction of London, and the contrast was noted and commented upon during the time that Newcastle was blockaded owing to the wars of that period, so that coal could not be sent to London. The unpleasant sensations experienced during fogs, with their effect on the healthy and robust as well as those who were ailing, together with their destructive effect on the numerous telegraph and telephone wires, and also on the insulators, were touched upon. Stress was laid upon the fact that, in addition to the black, sooty particles which make everything dirty, the sulphurous acid gas sent out from the chimneys of furnaces does a great deal of the damage said to be due to the soot, and Professor Freytag was quoted to show that more than ·003 volume per cent. of sulphurous acid in the air would do damage to vegetation. The author stated that from the analyses of twenty-two samples of coal of this district (kindly given by Dr. Wm. Wallace) the average amount of sulphur was ·658 per cent., and supposing that account were taken of all the dross and triping, &c., used for fuel, containing say ·9 per cent. of sulphur, this would mean that 9 tons of sulphur were given off in the form of sulphurous acid gas from every 1000 tons of coal burned. As near as the author can judge, about 9000 tons of coal are burned in Glasgow per day for all purposes. To show the value of analysing the smoke, the author quoted the following examples from Professor Ferd. Fischer, of Hanover: In the case of what might be called good firing there was a loss of 14 per cent. of the total heating power, while a case of bad firing showed a loss of 35 per cent. of the heating value of the fuel. Some cases tested gave results showing that 60 per cent. of the total heating power was going to waste, which, after overhauling the boiler seating and flues, and regulating the draught, was reduced to 7 per cent. loss of the heating value of the coal.

The following Acts of Parliament are in force for abating the smoke nuisance, the first and third being applicable to the whole of Scotland, while the second is purely for the city of Glasgow. "An Act for the Abatement of the Nuisance Arising from the Smoke of Furnaces in Scotland, dated 25th August, 1857," which enacts that "all furnaces shall in all cases be constructed or altered so as to consume or burn the smoke arising from such furnace," "provided always that the words 'consume or burn the smoke' shall not be held in all cases to mean 'consume or burn all the smoke,'" and the necessary powers and penalties for the carrying out of the Act are detailed. "The Public Health (Scotland) Act, 1867," in which it is enacted that "any fire place or furnace which does not as far as practicable consume the smoke arising from the combustible matter used in such fire place or furnace;" and "any chimney (not being the chimney of a private dwelling house) sending forth smoke so as to be injurious to health," the necessary powers and penalties shall be enforced. "The City of Glasgow Police Act, 1866," states that "every person who so uses, or causes, permits, or suffers to be used, any furnace or fire therein (except a household fire) as that smoke issues therefrom, unless he proves that he has used the best practicable means for preventing smoke, and has carefully attended to and managed the said furnace or fire so as to prevent as far as possible the smoke therefrom," shall be subjected to penalties which are clearly stated. To carry out the provisions of this Act, the city is divided into districts, each under a superintendent directly responsible to the Chief Constable. A certain number of smoke observations require to be made every week, and for this purpose each superintendent details a sergeant and constable for duty. Each observation lasts one hour, during which the constables must not lose sight of the top of the chimney, and must not be in sight of each other. After taking an observation, they leave a note of the fact with the owner of the works. The report to the Chief Constable states that the chimney in question emitted during the hour of observation so many minutes black or dense smoke, so many minutes light grey or whitish smoke, and so many minutes no smoke. It is held that dense or black smoke may be any colour so long as one cannot see through it, and in prosecutions under the Act this is the meaning attached to the term "black smoke." The Chief Constable hands the worst of these reports to the Police Procurator Fiscal, who in turn cites the worst offenders to appear and show cause why they have not abated the nuisance complained of. In no case is the Procurator Fiscal bound to prove more than that black smoke issued from the chimney, irrespective of the duration of such emission. It lies with the defender to show that such emission was unavoidable, and that he had done all in his power to abate it. At the same time, the use of bad coal will not be taken as a sufficient reason unless there be other factors showing that the said use of bad coal was unavoidable by the defender at the time of complaint.

In face of these Acts it might be asked why the nuisance still existed, and the answer is that they are only optional, and not compulsory; and the author stated that his experience of the working of these Acts gave rise to a good deal of feeling among manufacturers, which finds expression in a variety of ways which do not tend to the abatement of the smoke nuisance. He advocated that each town, county, or district should appoint an inspector, capable of dealing with the subject from the practical and scientific points of view, with power to visit any works at any time without notice, in order to judge of the best thing to be done in each case, and to have the power of instituting prosecutions where necessary; and his belief is that

*Abstract of paper read at the Graduate Section of the Institution of Engineers and Shipbuilders in Scotland, on the 6th December, 1887, by Mr. George C. Thomson.

Digitized by Google

this would meet with the approval of everyone concerned, and also of the public; and in support of his views he quoted the following from the report of the Chief Inspector under the Alkali Act: "I am not a little pleased to be able to add that, although there are more than three hundred manure works (including Scotland), all this change has been brought about without a single prosecution." The author is sanguine enough to believe that the same thing might be effected in the matter of the smoke nuisance, or at the very worst with but a very small percentage of the present prosecutions. He also believes that at no distant date all furnaces and chimeys may be brought under the working of the Alkali Act, or else of a special act, and inspectors may be appointed to deal with the smoke nuisance alone.

After explaining the process of combustion, and the loss arising from incomplete combustion, the author showed that with care in the construction and working of furnaces and their flues, and in the case of boilers that where there was sufficient power, there would be no smoke. After touching upon the principal mechanical contrivances designed and in use for smoke prevention, he passed on to consider the use of gas as fuel, and mentioning the Siemens and Wilson producers as well known, referred to the Brookes producer as being new and self cleaning, while the iron work was protected by a water jacket. It is a modification of the Wilson producer, but has not been long enough before the public to judge of its merits. The gas producer of Mr. Ludwig Mond claims to retain almost all the sulphur, and recover about half the nitrogen present, which is about three to four times more than that obtained hitherto by the distillation of coal in gas works or coke ovens, and the gas from it is smokeless. The principal novelty is the introduction of a larger quantity of steam or watery vapour, so regulated that the temperature of the producer is kept lower than usual, the heat not being allowed to exceed that indicated by dull redness, and the gas is equal to that produced under the older systems. Should it prove a general success the health of our towns would be greatly benefited, and one great source of damage to plant life done away with. The employment of forced blast for boiler furnaces, and the introduction of coal dust or powder for fuel, and furnaces for burning the same, such as that of M. Michel Perret, were briefly touched upon and described. From the foregoing it was evident that smoke could be consumed with advantage to everyone concerned, and the author trusted that the day was not far distant when the eyes and hearts of the weary toilers in our great industrial hives might be gladdened by the sight of flowers growing in our squares and gardens as luxuriantly as in the fresh country air, and that fogs might be done away with; but to enable this to come to pass an explicit and compulsory act was necessary.

Notes.

COTTON MILLS IN FRANCE.

Although both England and the United States have shown great progress in the cotton spinning industry, France does not make much headway. The quantity manufactured in the last named country remains stationary at about 110,000 tons, as does also the import of cotton yarn at about 130,000 tons. The American Consul at Rouen states that old fashioned spinning mills abound, and cannot possibly prove profitable with their antiquated machinery; newly erected mills have given a certain vitality to the trade, but are insufficient to control it. The reason for this is that they require a large outlay of capital, and doubts exist whether they will be able to compete for a length of time against foreign mills.

TRADE WITH PORTUGAL.

Owing to the delay which takes place in the publication of Portuguese statistics on foreign trade, the figures relating to the year 1885 are only now available; but late though they are, they contain some facts worthy of notice, for it is seen that the tendency of British commerce is to remain stationary, while that of other nations, and notably of Germany, is increasing. The imports from Great Britain were highest in 1873, when they amounted to £4,461,000, or about 59 per cent. of the total. Since then there has been a diminution in our trade, and in 1885 the British imports amounted to only £3,489,000, or 42 per cent. of the total. On the other hand the German trade, which in 1870 was only of the value of about £60,000, has risen to £833,000 in 1885. This success on the part of Germany is attributed to the cheapness of the goods and the activity of German agents in finding a market for them. The trade of Belgium is also increasing, the articles mainly concerned being woollen goods and metal.

ITALIAN IMPORTS.

The British Consul at Venice, in reporting on the trade of that port during 1886, attributes the falling off in the imports of silk and woollen yarns and manufactures to the augmented production of these goods in Italy. Owing to the low price of cotton in 1886, and to the establishment of some cotton mills in the Venetian provinces, the imports of cotton increased. It is stated that British exporters have to encounter, in all the markets of Venetia, the energetic competition of the German and French manufacturers, who are taking the trade out of our hands. The causes assigned for this are that the goods thrown on the markets by the German and French manufacturers, although of much inferior quality, bear the appearance of being as good as the English, and are sold at a much cheaper rate; that the said manufacturers, by means of active commercial travellers, are accurately informed of the wants of buyers, and are prompt to adapt their supply to the nature of the demand; and finally, that they generally furnish goods in a liberal way at three or six months' credit. British goods, however, still enjoy a very high reputation for their workmanship and lasting qualities, and would be given the preference by the buyer, but for the great difference of price.

AMERICAN BOUNTIES ON SHIPPING.

Among the Bills introduced in the United States Congress before adjourning for the holidays, there was one providing for the payment of bounties to American ships. Whilst there is but little likelihood of its passing during the present session, our American correspondent states that each year there are more representatives in favour of the idea. The present scheme proposes that the following bounties per gross ton shall be paid on all iron and steel vessels built in the United States and registered, after 1st July, 1888: Vessels under 1000 tons, $10 (£2) per ton; from 1000 to 2000 tons, $15 (£3) per ton; 2000 tons to 3000 tons, $20 (£4) per ton; and vessels over 3000 tons, $25 (£5) per ton; provided the vessels are built according to plans approved by the Navy Department, and subject to Government purchase for purposes of war within twenty-five years.

TEXTILES IN PERSIA.

In reporting on the trade of Tabreez for the financial year 1886-87, Consul-General Abbott says that the importation of coloured calicoes from Russia has not increased with the rapidity which was anticipated, and that even in the province of Khorasan, where it was believed they would become greatly in vogue, Russian prints are comparatively scarce, decided preference being given to Manchester goods. Grey and white calicoes and other piece goods, and 24 yard prints, were in fair demand; but prints of a superior quality did not prove remunerative. German and Austrian cloth found a ready sale at good prices, and some descriptions of French and Belgian cloths—"draps fins" and "draps de fantasie"—are beginning to gain a footing in the market. An Austrian merchant from Vienna has opened a store at Tabreez for the sale of clothing, haberdashery, and fancy goods; but no serious competition with the English import trade, as regards coloured and plain cottons, has yet set in from the Russian side. The Consul believes we shall be well able to hold our own if we combine superior cloth, good printing, and durable colours, with the designs best suited to the Persian taste.

PETROLEUM IN EGYPT

Information has occasionally reached this country with respect to petroleum discoveries in Egypt; but it has not been very definite. Some particulars are now given in a United States consular report, in which it is stated that petroleum was found on the Red Sea coast in 1885 at a depth of 150ft.; but that the flow ceased after a few days. It was then determined to make a geological survey of the district, and Mr. Mitchell, an American, who had charge of this, reported after an inspection of four months that there existed an extended field charged with petroleum. Dr. Tweddle, also an American, has a contract with the Egyptian Government to direct and superintend investigation. He was allowed £30,000 with which to buy boring apparatus and other necessary material for prospecting, and has had a large force at work at Gebel-el-Zeit, boring a number of holes, none of which, however, have reached a greater depth than those previously sunk by the Government. As yet, petroleum has not been struck in any of the holes, and the Consul considers it probable that oil will only be struck at a much greater depth. Very large sums of money have been spent—sums far in excess of what was first proposed and agreed upon—and the prospecting progresses very slowly.

AMERICAN SHIPPING CONVENTION.

A convention of the American Shipping and Industrial League was to be held in Washington from the 16th to the 19th inst. The League was instituted about two years ago for the purpose of promoting the development and distribution of the products of American labour by the extension of the merchant marine of the United States, and to establish thereby more intimate commercial intercourse with other countries by frequent and direct mail service. Most, if not all, shipbuilders and shipowners throughout the States belong to this organisation, and nearly all important industries are in sympathy with it. The principal railroad companies have decided to slightly reduce the fares of delegates to the convention. The League has been divided into the five following departments, in order that the work might extend throughout the entire country: The North Atlantic Coast, the South Atlantic Coast, the Gulf Coast, the Pacific Coast, and the Lake Shore and Mississippi Valley. These departments have held local conventions during the past year. The President of the League is the Hon. Joseph Wheeler, of Alabama, and in the circular calling the convention together he states that the object of the meeting is to consider the best means of protecting the native shipping industry, and to save the country from paying annually to foreign shipping companies the sum of £30,000,000.

MR. KRUPP AT SHEFFIELD.

According to *The Times* of Saturday last, Mr. F. A. Krupp, the head of the great Prussian arsenal at Essen, visited the works of Messrs. John Brown & Co., Limited, Sheffield, on the 12th inst. Mr. Krupp, who was accompanied by one of his staff, Mr. F. Asthöver, and by his London agent, Mr. Alfred Longsdon, was conducted through the works by Mr. J. D. Ellis, the chairman of the company. The special object of the visit was to witness the action of the gigantic hydraulic forging press, lately added to the plant of the Atlas Works. This press, which is believed to be the most powerful and efficient forging tool at present in existence, nominally exerts a total force of 4000 tons, but its actual full power is considerably greater. Three large furnaces, each capable of heating an ingot of 100 tons, prepare the work for the massive machine, and two travelling cranes, each capable of lifting 150 tons with ease, convey the forgings from the furnace to the press, and manipulate them as required. One man, who stands at the floor level in a cage suspended from the crane, and travelling with it, has under his hand four valves, by which he lifts, lowers, advances, retires, moves sideways, or revolves the forging on its own axis. A second man works the lever which governs the strokes of the press, and by observing an index in front of him regulates with the utmost nicety the distance from the anvil at which the top tool is to cease its advance. A forge master and several furnace men are also required to superintend and to feed the apparatus; but its working is entirely under the control of the two men referred to. Mr. Krupp was so thoroughly satisfied with the machine that he ordered one precisely like it for his own works from Mr. Walker, of Messrs. Tannett, Walker, & Co., the makers of the press, who was present during the proceedings. At Essen the forgings are all done by hammers, which are still used in Sheffield for several kinds of forgings. Mr. Krupp also witnessed several other processes of steel manufacture.

THE MINERAL RESOURCES OF BOSNIA.

Previous to the occupation and administration of Bosnia by Austria-Hungary, which took place in the year 1878, the iron industry of the former country was well developed, and sufficed not only for home requirements, but a large amount of manufactured articles, especially scythes, was also exported to neighbouring countries. The change of Government, however, the laying down of the railway line Brod-Sarajewo, and the formation of numerous highways, facilitated the importation into Bosnia of cheaper manufactured iron, to the detriment of the native product. The Bosnian iron industry has therefore considerably declined. When Austria first occupied Bosnia, the Ministry in Vienna devoted some attention to the development of the iron industry in that country. Investigations and borings under Government supervision were made, with partly successful results, and this led to the foundation, in 1881, of the Bosnia Company. This company carried on the work already begun by the Government, and found a fair amount of chrome and manganese ore. In January, 1886, the Austrian Government took over the administration of the Bosnia Company, and commissioned Herr Bruno Walter, formerly director of the company, to draw up a report on the condition of the mineral resources of Bosnia. This report, which has now been published by the Government for Bosnia and Herzegovina in a book entitled "Beitrag zur Kenntniss der Erzlagerstätten Bosniens," gives a fair account of the mineral deposits of the country, amongst which are the following: Spathose iron, red and brown iron ore, specular iron ore, iron and copper pyrites, manganese ore, gold and silver, antimonite grey copper, galena, and chrome ore. Bosnia is very rich in ironstone, which is found in the extreme north-western districts and in the south. Manganese ore suitable for the manufacture of ferro-manganese is found near Cevljanovic. Silver mining was formerly carried on in the district of Srebrenica, but was discontinued when the Turks took possession of the country. Well informed mining engineers are of opinion that there exists a large amount of silver ore in the district still untouched, and state that they expect this branch of trade will again flourish. Quicksilver is not found in any great quantity, but a fair amount of chrome ore exists in the valleys of Dubostica, Tribija, and Krijava.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

6th January, 1888.

228. Holland, W. — Mechanism for stopping engines.
229. Shaw, J., & others — Apparatus for polishing steel wire.
231. Kitson, J., & others — Machinery for making healds for looms.
235. Smith, J. — Spinning machinery.
248. O'Brien, J. O. — Rock boring machinery (*Bomet*).
252. Green, W. R. — Hydraulic lifts.
254. O'Neill, W. P. — Hydraulic tramway locomotive.
261. Wickham, W. R. — Breech loading fire arms.
262. Rush, J. T. — Boot sewing machines.
270. Priestman & Priestman — Hydrocarbon engines.
273. Williams, T. — Machines for cutting plastic substances.
277. Gubbins & Bayley — Machines for making horse nails.
278. Cayley & Courtman — Projectiles.
280. Williamson, G. B. — Apparatus for splicing wire (*Hughes*).

7th January, 1888.

281. Rogers, J. E. — Compressed air motors.
301. Ramsay, J. — Apparatus for washing coal.
311. Trelease, E. H. — Air pumps.
315. Hewett, R. W. — Furnaces.
321. Hassel, W. — Atmospheric hammer.

9th January, 1888.

335. Eves, J. V. — Spinning frames.
339. Falconer, R. — Furnace tube cleaner.
340. Taylor, F. D. — Anchors.
344. Niven, J. — Anchors.
350. Parks, E. F., & others — Shrinking heated wheel tyres.
351. Hitt, T. — Anchoring vessels.
352. Drake, G. — Appliances for raising sunken ships.
357. Scott, L. K. — Carriages for machine guns.
361. Sellner, L. — Condensers.

10th January, 1888.

367. Royston, E. R. — Steam engines.
374. Willis, J. — Steam wheels as motive power to propel ships.
376. Dixon & Gradwell — Spinning machinery.
385. Bolton, J. — Sewing machines.
387. Burgess, H., & others — Shuttles and weft carrying bobbins.
400. Lake, H. H. — Sewing machines (*Tucker*).
401. Harvey, H. A. — Low steel.
403. Sanday, W. — Circular saw.
406. Graepel, H. — Pulverising ores.
407. Tomson, W. H. — Freezing machines.
414. Kingdon, G., & others — Quadruple expansion engines.
415. Bowker & Williams — Looms.
418. Darby, J. H. — Manufacture of steel or iron.
419. Edwards & Smith — Gas engines.
426. Haddan, R. — Sewing machines (*Hensel*).
427. Griffiths, G. — Rag engine.
428. Allday & Allday — Forge bellows.

11th January, 1888.

430. Ashworth, H. — Mules.
431. Keymer, H. J. C. — Improvements in motors.
439. Cotton & Cotton — Machines for looped fabrics.
442. Taylor & Taylor — Flues of boilers.
443. Biertumpfel & Biertumpfel — Candle moulding machines.
445. Sims, T. P. — Machine for making scorifiers, cupels, and crucibles.
456. Huese, F. A., & others — Apparatus for printing.
458. Smith, J. — Warp looms.
461. Hett, C. L. — Turbine governors.
464. Allen, J. — Propulsion of lifeboats.
466. Tempest-Radford and Morton — Manufacture of pile fabrics.
467. Cornely, E. — Embroidering machines.
474. Scott, T. W. — Vessels propelled by screws.
478. Westerman, J. A. — Endless traction railways.

12th January, 1888.

484. Pemberton, W., and others — Looms.
486. Ireland, J. — Railway chairs.
497. Lister, H. — Weaving pile fabrics.
498. Edmondson & Edmondson — Printing, embossing, and shading textile fabrics.
508. Parkinson, G. S. — Aërial propulsion.
512. Sington, T. — Gas engines.
513. Boyd, D. — Projectile.
517. Pickering, G. F. — Calculating machines.
519. Redfern, G. F. — Thrashing machines (*Damanion*).
520. Verini, G. F. — Chimneys.
523. Orcel, A. — Furnaces.
529. Johnson, J. Y. — Mercurial air pumps (*Doerr and Mace*).

ELECTRICITY.

6th January, 1888.

224. Böhm, E. — Electric incandescent lamps.
225. Abbott & Douglas — Electric battery for miners' lamps.
227. Lewis, J. S. — Telephonic apparatus.
242. Davies, J. H. — Electrical measuring instruments.
249. Roe, J. T. — Electric meters.

7th January, 1888.

293. Parker, T. — Dynamo-electric machines.
295. Parker & Rees — Electric meter.
296. Parker, T. — Switches for electric circuits.
302. Parker, T. — Electric meter.

9th January, 1888.

366. Abel, C. D. — Electric arc lamps (*Siemens and Halske*).

10th January, 1888.

396 & 424. Lorrain, J. G. — Continuous currents of electricity.
416. Tucker, J. H. — Electrical measuring instruments.

11th January, 1888.

472. Webster, W. — Treating sewage by electrolysis.

12th January, 1888.

506. Dorman & Smith — Incandescent electric lamps.
507. Berg, E. — Controlling signal telegraph.
531. Edmunds, H. — Generation, distribution, and control of electricity.

CHEMISTRY.

6th January, 1888.

245. Stead, W. H. — Manufacture of gums.

7th January, 1888.

305. Wylde, J. R., & others — Chlorate of potash.
314. Ducat, F. A. — Discolouring and disodourising product.

9th January, 1888.

353. Levi, S. J. — Photographic lamps.
356. Hart & Bishop — Lights for photographic purposes.

10th January, 1888.

370. Emmens, S. H. — Explosives.
377. Park, J. — Chromium.
390. Andreoli, E. H. M. — Halogens.
405. Perry, E. W. — Photographic sensitive films.
421. Lewis & Phillips — Refractory ores.

12th January, 1888.

487. Orr, A. — Nitro-cellulose.
524. Farmer, E. H. — Photographic printing.
530. Arnold, J. — Deodorising sewage.

MISCELLANEOUS.

6th January, 1888.

223. Wilkins, T. — Knife cleaning machines.
226. Williams, J. — Valve gearing.
230. Thompson, J. — Stoves.
233. Coles, R. W. — Manufacture of type.
237. Thomson, G. — Oil feeding for the bearings of shafts.
238. Roberts, A. — Equilibrium valve.
239. Reid, F. T., & others — Safety gas burner.
243. Sunyé & Blumberg — Nails.
250. Hughes & Letts — Locking the nuts on fish plates.
253. McInnes & Morriss — Machine counters.
256. Sawer, J. C. — High pressure tap.
258. Heckford & Stanley — Lock and latch.
259. Stanley, W. F. — Explosives, and apparatus connected therewith for producing instantaneous light for photographing.
263. Lock, C. — Couplings for railway vehicles.
264. Redfern, G. F. — Apparatus for drying substances (*Raty & Lambert*).
265. Redfern, G. F. — Grinding substances (*Raty and Lambert*).
275. Abel, C. D. — Brake mechanism (*Westinghouse*).

7th January, 1888.

282. Enright, J. — Gas lighting.
287. Clarke, A. — "Sorting tools" for dressing pottery ware.
288. Simmons & Cravos — "Hanks" for fastening ships' sails.
291. Allan & McBlain — Die for punching holes in iron and steel plates.
292. Fonseca, J. H. da — Railway signalling.
298. Bates, J. — Velocipedes.
299. Roby, G. — Oil lamps.
304. Boult, A. J. — Means for distributing oil upon the surface of water (*Meissel*).
306. Heard, T. H. — Railway buffers.
309. Hollands, S. H. — Fans for forced draught.
310. Martin, S. — Velocipedes.
316. Stevens, J. S. — Reefing schooner main sails (*Stevens*).
317. Powell, D. — Centre board countervail.
319. Mallett, C. S., & others — Vacuum gauges.
320. Palfroy, A. — Sails for yachts.
322. Simpson, W. S. — Glass bottles.
325. Comings, W. R. — Tubes.
326. Blanchard, M. H. — Terra-cotta fire proof construction.
329. Morland & Morland — Dyeing woollen skins.

9th January, 1888.

332. Key, J. T. — Corrugated steel scoops.
336. McKay, J. B. — Machinery for dyeing yarns.
338. Briddon, G. — Dust collectors.
341. Gorton, W. S. — Vertical bar fencing.
342. Considere, E. — Safety guards for the front of tram engines.
346. Thame, J. R. — Barrels manufactured from paper.
355. Vigouroux & Drivet — Tubes.
358. Schulhof, J. — Boxes for packing cartridges.
359. Rose, G. — Spray lamps.
360. Darling, J. — Couplings for railway carriages.
365. Price, J. — Ventilating tanks for carrying petroleum.

10th January, 1888.

371. Jones, J. — Apparatus for treating malt.
372. Gibbs, W. — Lead glazing.
375. Woodhead, M., & others — Velocipedes.
379. Pullinger, T. C. — Velocipedes.
381. Romain, H. — Draught preventer.
383. Pearce & Besson — Methods of holding plate glass while roughing, smoothing, or polishing.
384. Inman, H. — Trimming machines.
386. Thompson, W. P. — Wood planing tools (*Brown*).
391. Vine, J. W., & others — Lubricating and moistening rags.
394. Wilholft, F. — Vulcanised soft rubber.
395. Taylor, T. H. — Lubricants.
402. Lake, H. H. — Dyeing textile materials (*Weldon*).
404. Sanday, W. — Vices.
408. Laidman, J. H. — Stern posts.
411. Shannon & Bennison — Edging articles of textile fabric.
412. Ambjorn, P. (Comte de Sparre) — Cartridges.
413. Norris, J. — Beer engines.
417. Darby, J. H. — Burning lime.
425. Haddan, R. — Knife cleaning machines (*Hensel*).

11th January, 1888.

433. Taylor, R. — Facing nuts.
436. Thomas, A. — Swing bucket for unloading ships.
440. Barbour & Combe — Applying liquid to yarns whilst being twisted.
444. Hall, J. — Grate backs.
448. Brown, C. — Atmospheric stove.
453. Urquhart, R. J. — Fluid meters.
454. Cutler, S. — Telescopic gas holders.
457. Forsaith, T. — Hand saw.
459. Andrews, S., & others — Axles for tram cars.
460. Statham & Chudleigh — Stereotype plates.

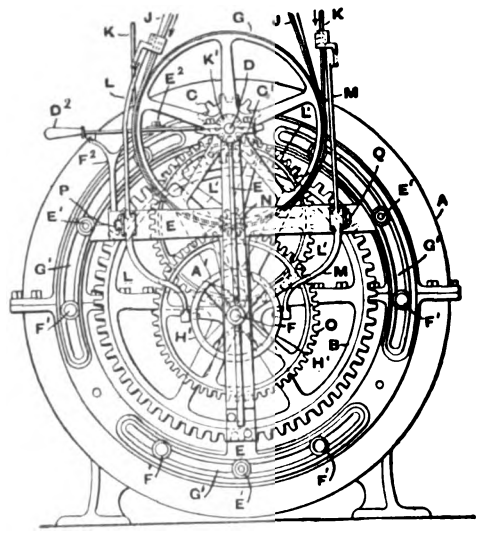
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

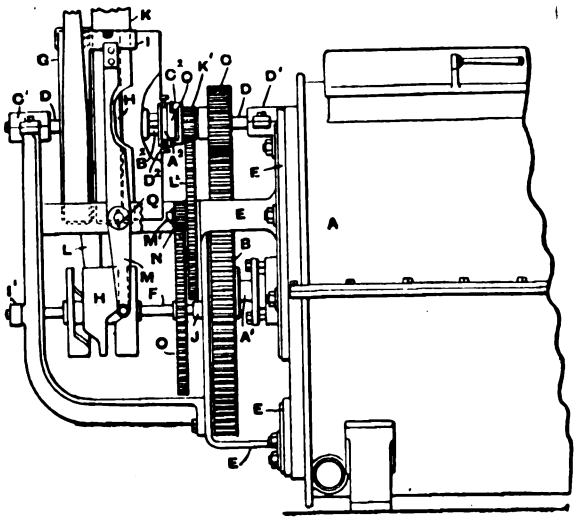
Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Shearing Sheet Metal.—*D. Smith, Jun., Wolverhampton.*—The sheet of metal to be sheared is gripped by a bar and held firmly in its position as determined by means of the shearing gauges. The mechanism employed will be understood by reference to the accompanying diagram, which represents a



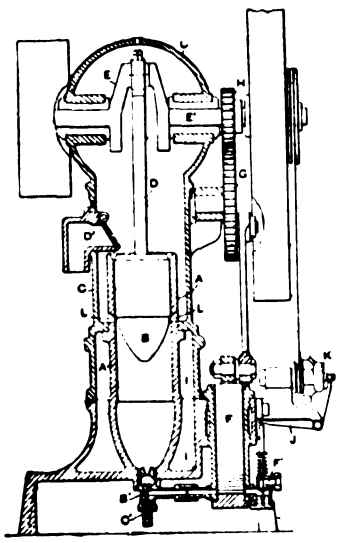
front view of the machine. A is the grip bar, which is carried immediately in the front of the shear arm; and A^1 A^1 are straps or links connected to the bar A by means of pins E^1, whose lower ends are connected to the side levers B. These levers are fulcrumed at their ends furthest away in the diagram, and their nearest ends are boxed out to carry the rollers C^1. The cams C C are keyed to the crank shaft, and spiral springs D round the rods D^1 bear up against the levers B. The sheet to be sheared is adjusted in position against suitable gauges, and motion is imparted to the shaft and the cams by means of the wheel E. The cams depress the levers B, and cause the grip bars to grasp the sheet. When the cams revolve off the rollers, the springs D force up the levers B, and consequently the grip



Digitized by Google

bar A. The pins E¹ are provided with shoulders, in order that they may be adjusted for different thicknesses of sheet metal. By means of the grip bar acting in combination with the shear blades, the sheet may be readily edged. The guides carrying the shear arm and grip bar are set back by means of the pins H¹, through a distance not less than the thickness of the sheets to be edged, and thus as the shear arm descends it edges down the sheet at right angles to its plane. The grip bar, pressing close on the edge of the sheet, insures the desired straightness. The inventor makes five claims for these improvements described.—No. 1940. February 8th, 1887. 8*d*.

Reversing Belt Gear.—*A. H. Reed.* (*H. E. Smith, New York, U.S.A.*)—This invention is a device for imparting reverse motions to a shaft by means of belt gearing. In the example illustrated in the figures, the apparatus is attached to a cylindrical washing machine, but the mechanism is nevertheless applicable to any other machine. A represents a frame or casing in which is journalled the shaft A¹. This shaft has

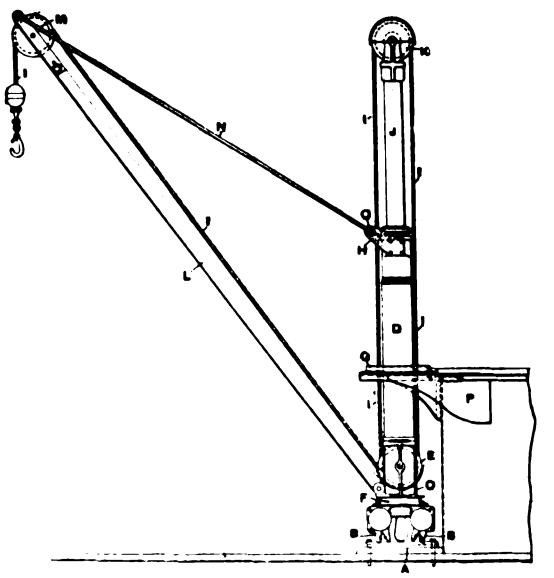


rotary motion from the driving shaft D imparted to it through the toothed gearing B C. Three pulleys G H I are mounted on the shaft D, G and I being loose and H fixed thereon. Two belts J and K, the former twisted and the latter straight, connect these pulleys with the line shaft, and according as one or the other works on the fixed pulley, the rotation of the shaft D takes place in one direction or the other. The train of wheels K¹ N O impart the rotation of the shaft D to the shaft F. The latter shaft carries a cam H¹, which works the levers L and M. The belts J and K are thus moved in a lateral direction off one pulley and on to another, and the object of the invention is

attained. The cam is so formed that first one lever and then the other is moved, and the reversing of the motion is not effected too suddenly. A clutch is provided on the shaft D, so that the reversing mechanism may be thrown out of gear at any time. The inventor makes three claims for these combinations.—No. 106. January 4th, 1887. 8*d*.

Rock Boring Apparatus.—*J. Thom, Riccarton, Ayr.*—This invention has for its object the reducing of the cost of diamond drills for rock boring purposes, and the shortening of the operations to be carried out in its use. The machine is mounted on wheels, and its frame carries a horizontal shaft provided with fast and loose pulleys, over which the driving belt travels. This shaft also carries at its sides a pair of spur pinions of different diameters, one of which is in gear with a corresponding spur wheel on the shaft of a chain barrel. The pinions and cog wheels are of different sizes, according to the speed at which the chain barrel requires to be driven when winding up the boring rods and drill. At the central part of the shaft is a bevelled wheel, which gears with a pinion on the inner end of a horizontal shaft situated at right angles to the other. The outer end of this shaft is provided with another bevelled wheel, which gears into a bevelled pinion. This latter pinion drives the shaft to which the boring rods are coupled. The latter shaft and its connections are pivoted at the inner end, and are capable of being moved sideways upon a quadrant, so that they may be shifted out of the central position when it is desired to lift the boring rods and drill by the chain barrel and chain. To prevent too much weight from acting on the diamond drill when the hole becomes deep, a provision is made for counterpoising the weight of the rods, which consists of a second chain barrel, one portion of which is of larger diameter than the other. The chain is caught by a hook attached to another chain, which is wound round the smaller portion of the second chain barrel, and a counterpoise is suspended from a chain upon the larger portion of the barrel. In order to release the rods when a piece of rock chokes the bore hole, a shaft is provided with handles which are caused to operate on the suspension chain, whereby the rods may be moved upwards or downwards in the hole until the obstruction to their revolution is removed. The inventor makes three claims for these arrangements and combinations, together with the counterpoising apparatus.—No. 94. January 4th, 1887. 11*d*.

Internal Combustion Heat Engines.—*H. H. Hosack, Liverpool.*—According to this invention, the air and the fuel are introduced separately into the cylinder, in order that no premature combustions shall take place. The annexed diagram represents a vertical sectional elevation of an engine designed according to the suggested improvements. The cylinder A has a water jacket I. A casing C incloses the connecting rod D and the crank E, and constitutes an air chamber having an air inlet valve D¹. The gas pump F is worked by the spur wheel G H. The exhaust valve is worked by a bell crank lever, which is operated by a cam projection on the spur wheel G, and the ignition valve is of the heated tube type worked by another cam on the spur wheel G. The gas pump F is provided with a suction valve F¹ and a delivery valve B¹. The valve F¹ is an ordinary lift valve, and serves to govern the supply of gas. When the engine runs above its normal speed, the lever J keeps the valve F¹ open, and so upon the compression stroke of the pump the gas is forced back into the gas main, and not into the cylinder. The delivery valve B¹ is kept upon its seat by a spring C¹, which is of sufficient strength to prevent any gas entering the cylinder from the pump until it is compressed to a certain atmosphere. The pump may be arranged to inject all the gas into the cylinder, so as to render the charge



combustible just before the compression stroke of the piston is terminated. During the compression stroke air is introduced through the valve D¹. In the succeeding out stroke the charge is ignited and the piston is urged outwards, at the same time compressing the air in the reservoir C. Just before its termination, some part of the products of combustion escapes through the opening of the exhaust valve, and when the piston has reached its extreme position, the ports L are opened, and the compressed air from C rushes through into the cylinder and expels a large portion of the remaining products of combustion. The whole space of the cylinder is thus occupied by pure air, and the more perfect absence of products of combustion thus insured enables the inventor to obtain a more complete combustion, and hence a more effective stroke. The inventor claims the method of expulsion of the gaseous products, the cycle of operations, the mode of supply of fuel, and the construction of the engine.—No. 888. January 20th, 1887. 11*d*.

Looms.—*E. Woodhouse & J. J. Grimshaw, Leeds.*—The object of this invention is to provide means for reversing the warp beam without disarranging the let-off motion. The drums on the ends of the beams, round which the weighted cords are wound, are connected to the beam by a pawl and ratchet mechanism, in such a manner that the beam is free to be turned back without actuating the drums. The inventor claims the improvements in let-off motions for the before mentioned object, and the combination with a warp beam of a ratchet wheel rigidly fixed to the beam, and a loose drum mounted on the beam having a pawl adapted to engage with the wheel.—No. 2091. February 10th, 1887. 8*d*.

Carding Engines.—*J. McQueen, Manchester.*—This invention consists of improvements in the method of grinding the flats from the face which rests on the elastic bend. A bracket is attached to the engine framing, and carries a horizontal shaft, to whose inner end is fixed a wheel gearing into the snugs on the flats. This wheel is formed so that the part which comes into contact with the snug is held up by a spring. On the other end of the shaft is fixed a bevel, which gears into another on an upright shaft; on the upper end of the latter shaft a wheel is secured, which has projections on its under side to suit the angle and width of the flats. The motion of the flats is transmitted to the last named wheel from the elastic wheel which is driven by the flats. The elastic wheel lifts the flats up against the projections on the under side of the wheel, and brings the points of the wire on the flats into line when passing under the grinding roller, thus making all the flats alike in the relation of the working parts to the points of the wire. In another form of the invention, an endless chain is placed above the flats, each link of which corresponds to the end of the flats in width and angle. By the action of the elastic wheel, the flats are lifted up against the links of the chain, which are held in line by a straight piece fixed inside of the chain. The inventor makes two claims.—No. 3050. February 28th, 1887. 8*d*.

Ship Cranes.—*W. Shapton, London.*—The inventor has designed this hydraulic crane with a view to keeping it entirely above the deck line. The bottom of the post is stepped on the deck, and the upper part is supported by a collar or bracket from a deck house or from a mast. The tie rods of the jib are secured to the post above this collar, and the jib itself is attached to the pillar between this collar and the footstep. The lifting chain passes through this collar, and the slewing cylinders are fixed upon the deck at the foot of the crane. The appended diagram represents an elevation of a crane constructed according to this principle. A is the footstep fixed to the deck, and C is the post of the crane, which consists chiefly of the main

hydraulic cylinder D. The ends of the slewing cylinders are shown just above the footstep, and F is a drum on the crane post which receives the slewing chain. The apparatus used for slewing the crane consists of chains fixed to the cylinders at B, and passing over pulleys on the ends of the rams which work in these cylinders. The ram J supports a pulley K at its summit, and the chain I being attached to the foot of the crane passes over the pulley K, under the sheave E and over M, which is placed at the extremity of the jib L. The tie rods N attached to the jib head are connected with the lug heads H by means of the bar O. These parts and their joints are made in such a manner that the tie rods can be easily taken off when the crane is not in use. P is the bracket which serves as the upper support of the mechanism, and in the drawing takes the form of a collar surrounding the cylinders. The post is hereby held steadily, but is nevertheless free to turn round together with all its gearing. The inventor makes four claims for this crane.—No. 1807. February 4th, 1887. 8*d*.

Boiler Flues.—*D. Adamson, Dukinfield, Cheshire.*—This invention relates to improvements in the manufacture of tubes and shells of boilers, and its chief object is to construct and arrange a machine which will in one operation flange a solid tube at both ends, and simultaneously roll out of the solid metal one or more rings. A pair of rollers are placed horizontally; one of them is provided with grooves on its periphery, and is supported in the main frame of the machine, and is made adjustable by means of suitable mechanism; the other roll, which is not adjustable, is of comparatively small diameter, with a flange at each end, and grooves corresponding to those of the other roll. The non-adjustable roll is supported at one end in a strong bracket securely bolted to the housing, and this bracket carries an arm which extends to the opposite side of the machine, where it has secured to it a pedestal for supporting the other end of the non-adjustable roll. The arm, pedestal, and the other parts are arranged to permit of solid tubes being readily placed between and removed from the rolls, thus dispensing with the hinged journal commonly employed in such machines. In operation the adjustable roll is moved back far enough to allow the heated solid tube to be passed over the non-adjustable roll and its fixing, and up to a stop. The adjustable roll is then moved quickly forward so as to press the tube between the two rolls, which as they revolve flange the ends and simultaneously form the rings on the tube. The inventor makes five claims for the combinations and improvements.—No. 535. January 13th, 1887. 11*d*.

Furnace Doors.—*A. W. Robertson, West Ham, Essex.*—The improved furnace door is constructed of a sheet of metal, preferably steel, provided with apertures for the admission of air. The bottom edge of this plate is turned over so as to carry a pin or axle, the ends of which are carried in bearings formed in a piece of angle iron which surrounds the furnace mouth. A flame or baffle plate is attached to the door at a suitable distance from it, and is also furnished with air admission holes. The door is held in its closed position by means of a weighted lever latch mounted between two lugs on the furnace front. Suitable springs may be attached to the door to ease the fall. Claims: (1) The construction of the hinge by bending over one of the edges of the door so as to envelope a pin or axle, the ends of which are mounted as described; (2) the application of springs to ease the fall; and (3) the general construction and arrangement described.—No. 13027. September 26th, 1887. 6*d*.

Digitized by Google

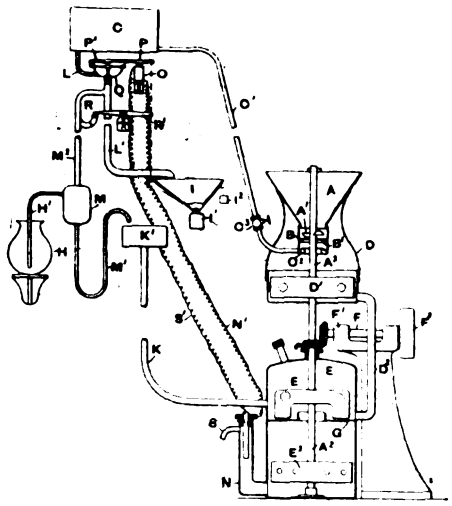
SPINNING MACHINES.—*S. Tweedale, Accrington.*—This invention involves an improvement in the construction of the step and bolster bearings for spindles, described in Letters Patent No. 2095 of 1881. Instead of the spiral springs and nuts as before used, the inventor now employs a collar, so made as to fit closely to the inside of the bolster carrier. This closeness of fit serves to support the spindle in an upright position when at rest. A part of this collar is made into a shell by boring or cutting away part of the metal between the outside and the centre; and a number of grooves are cut through this shell part for the purpose of rendering it elastic, thus allowing the lever end of the bolster tube to have a limited amount of lateral motion. After the insertion of the bolster tube in the base, a brass cap is forced on the top of the base in order to prevent the tube being lifted out of its position. The inventor makes one claim for the improvement described.—No. 1737. February 3rd, 1887. 8*d.*

WINCHES.—*M. Archer, Gateshead.*—The frames of the winch are formed in the ordinary shape, and are made of cast iron plate or angle iron. Instead of the usual drum, the inventor employs a series of externally convex iron bars. Their convexity is of such a degree that the exterior curved surfaces of the bars are parts of the surface of a cylinder whose axis coincides with the axis of the bars. These bars are carried between wrought or cast iron plate ends, in one of which they are riveted, while they are allowed to slide through holes in the other end. These ends of the drum are both secured to the shaft with which they revolve, and the length of the barrel may thus be adjusted at will. In order to hold the pinion of the winch in or out of gear, a sliding block is formed which slides upon the top cross stay of the frames forming the body of the winch. The block is secured in either of two positions by means of a tongue piece fitted into it, which may be dropped into one of two notches in the cross stay. The block has two lugs upon it, between which the pinion of the winch is placed, and the driving spindle runs through both the lugs and the pinion, so that the position of the sliding block determines the position of the pinion. The inventor claims the method of altering the length of the barrel, and the method of holding the pinion in or out of gear, as described.—No. 1842. February 5th, 1887. 8*d.*

PNEUMATIC HAMMERS.—*G. Glossop, Sheffield.*—These improvements relate to pneumatic hammers, and consist in the application of a brake by means of which the action of the tup may be stopped or retarded. A brake block is let in the inside face of the standard, and is moved outwards against the tup by the horizontal action of a wedge, which is fitted in a recess between the brake block and the standard. The wedge may be operated by any suitable mechanical arrangement, such as a treadle or hand lever. Claim: In pneumatic hammers the combination with the tup of a suitable brake by means of which the tup may be retarded or stopped substantially as described.—No. 1706. February 3rd, 1887. 8*d.*

ROLLING SEAMLESS TUBES.—*W. P. Thompson, Liverpool.* (*C. Kellog, Buffalo, New York.*)—These improvements are applicable to a form of rolling mills described in Letters Patent No. 2844 of 1883. The object is to provide means of adjusting both the rolls in the vertical and horizontal pair simultaneously, to furnish means for maintaining the free end of the mandrel in proper position, to allow of adjustment of the rolls supporting the material operated on, and to supply means of preventing the bending of the mandrel during the process of rolling. The inventor makes thirteen claims for the combinations of parts employed.—No. 14042. September 6th, 1887. 8*d.*

ELECTRICITY.



SECONDARY BATTERIES.—*C. D. Abel, London.* (*A. Dun & F. Hasslacher, Frankfort-on-the-Main.*)—The object of this invention is to provide an accumulator whose durability is less limited than of those at present in use. The negative plate consists of retort carbon, or of a metal which is insoluble in caustic alkali, such as copper, iron, aluminium, &c. The depolarising substance is a metallic oxide, also insoluble in caustic alkali, for example, oxides of silver, copper, manganese, nickel, cobalt, or bismuth, all of which bodies can pass to a higher state of oxidisation. Carbon powder may be mixed with the depolarising substance in order to increase its effectiveness. When mixed with water the depolarising agent is formed into a plastic mass, and in that state is applied in thick layers to the surfaces of the negative electrode. The prepared electrode is wrapped in a covering of asbestos, or other tissue, which will allow the exciting liquid to penetrate it. The positive electrode consists of a plate of carbon, or metal insoluble in caustic alkali, copper being used by preference. The exciting liquid is a more or less concentrated solution of zinc oxide or lead oxide in caustic alkaline lye. The negative and positive electrodes are arranged alternately, and are respectively connected to a common pole. In order to prevent the action of atmospheric carbonic acid upon the exciting liquid, this should be covered with a layer of paraffin oil, or the vessel may be hermetically closed with solid paraffin or gypsum. This cover is provided with an opening closed by a ball valve, permitting the escape of the gases given off, and serving for the introduction of water to make good the quantity converted into gases during the changing operations. The inventors make one claim for the battery as described.—No. 1862. February 5th, 1887. 6*d.*

CHEMISTRY.

PURIFICATION OF COLOURING MATTERS.—*R. Reid, Glasgow.*—This invention relates to improvements in the method of separating fine solid insoluble matter or grit from alizarine, starch, and other solutions used in the operations of calico printing. The inventor effects this separation by passing the alizarine or other article through silk cloth, of the kind known as silk bolting cloth, such as has been used in flower bolting machines. The result of this treatment is that the grit is separated effectually, and the doctors' streaks in calico printing are prevented.—No. 3304. March 4th, 1887. 4*d.*

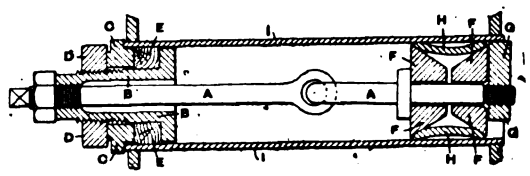
METHYLENE BLUE.—*O. Imray, London.* (*Farbwerke vormals Lucius & Brüning, Hoechst-am-Main, Germany.*)—The chlorzinc contained in ordinary methylene blue of commerce has an unsatisfactory effect on textile fabrics. In order to obviate this disadvantage, the zinc is to be precipitated from the solution by means of alkalis, or sulphides, oxalates, or phosphates of alkalis, and by the addition of common salt, or by re-crystallisation the dissolved colouring matter is to be separated from the filtrate. The inventor makes one claim for this improvement.—No. 2985. February 25th, 1887. 4*d.*

APPARATUS FOR GENERATING CARBONIC ACID.—*J. Mangnall, Manchester.*—The method and apparatus here invented are shown in the accompanying diagram. The basic carbonate is introduced into the chamber B, through the perforated bottom of which it falls into the vessel D, after having been mixed with a supply of water from the reservoir C. The powder is thoroughly dissolved by the stirring action of the rotating arm D^1, which is fixed to the shaft A^2. The pulley F^2 supplies the motive power to this shaft by means of the bevel gearing shown

in the diagram. The carbonate enters the vessel E through the pipe D^2, and the acid by means of the pipe K. The cistern C empties itself periodically down the pipes L L^1 into the vessel I, which can cant on its fulcrum I^1. The suction action caused by the fall is employed to exhaust the air within the receiver M, which is connected by the trapped pipe H^1 with the acid supply H, and likewise has a pipe M^1 leading to the vessel K^1, and thence by the pipe K to the generator E. The acid will flow up the pipe H^1 and the vessel M through the syphon M^1 and into the generator E. The regulation of the supply of acid is effected in the following manner, while the carbonate supply is not interfered with: The waste pipe N is made of copper, and has an insulated zinc stopper S. These two pieces of metal act as a battery when there is a preponderance of acid in the liquid contained in the vessel N. The current thus generated is communicated to the magnet O, which attracts the armature P, and thereby the supply valve Q will be closed, the air valve R opened, the vacuum in M destroyed, and the flow of acid to the generator stopped, while the carbonate supply is not interfered with. The excess of acid is thus neutralised. The inventor makes five claims: For the method of preparing the gas, for the mode of supplying the acid, for the regulation of the quantity of acid, and for the construction and combination of the parts of the apparatus.—No. 1832. February 5th, 1887. 8*d.*

PHOTOGRAPHIC IMAGE ON GELATINE SURFACE.—*H. Sutton, Ballarat, Victoria.*—This invention is designed for the purpose of automatically converting a photographic image on a gelatine surface into a relief or intaglio printing surface, which will show the half tones of light and shade. The inventor takes an ordinary sensitised gelatine plate bearing a photograph broken up by any pattern or grain, and immerses it in warm water until the gelatine has swelled to a certain extent. The plate is afterwards cleansed of any free water remaining on its surface, and it is subjected to a gradually increasing heat until all the water has been driven off. Those parts of the gelatine which are unaffected by the action of light, and which are freely absorbent of water, melt and are drawn by capillary attraction under the unmelted portions, thus forcing up the latter into relief. The inventor makes one claim for the process described.—No. 15722. November 16th, 1887. 4*d.*

MISCELLANEOUS.



FIRE EXTINGUISHING SPRINKLERS.—*F. Grinnell, Providence, Rhode Island, U.S.A.*—This invention relates to systems of fire extinguishers in which the distributing pipes are filled with air under a low pressure, while the water is held in check by a valve of suitable construction under the control of the light air pressure. Certain combinations are introduced by this invention whereby the air pressure in the pipes is made to act in direct opposition to the water, thus doing away with all intervening mechanism heretofore employed. A valve and valve casing are placed between the air pipe and the water pipe, and a device is arranged for opening the ports that form the valve chamber to the two pipes. The inventor makes thirteen claims.—No. 1512. January 31st, 1887. 1*s.* 1*d.*

FRICTION CLUTCHES.—*J. Marshall, Gainsborough.*—This invention applies more particularly to the coupling of two shafts in line. On the end of one shaft is fixed a disc with a flange, upon the internal side of which bear the coupling devices carried by the other shaft. The other shaft has fixed to its end a circular box with a number of radial divisions, which accommodate the coupling devices. These devices consist of an outward portion and a stem, which can slide outwards and inwards in a boss. Each boss acts as a guide for the stem, whilst the sides of the upper parts of the divisions act as guides for the outward portion of the coupling device. Each coupling device is internally screwed, and another screw engages with it which abuts against the inner side or bottom of the division. The screws are provided with levers in order to turn them, and are connected by links with a collar sliding on the shaft, and operated by a forked lever. When the collar is thus slid in one direction, the levers are all operated so as to give a movement of equal extent of partial rotation to all the screws, and they consequently cause the coupling devices to move outwards, and bear on the portion of the adjacent shaft. In order to allow for the adjustment of the levers on the screws, for the purpose of taking up wear, the engagement is effected by a series of ribs and grooves round the interior of the hole in the lever, through which the neck of the screw passes, and also in the neck of the screw. The inventor claims the employment in friction clutches of screw spindles as described, the means of adjustment, and the general construction of the clutch.—No. 1805. February 4th, 1887. 8*d.*

FIRE EXTINGUISHERS.—*D. Spence, Glasgow.*—This invention involves a new arrangement and construction of portable chemical fire extinguishers. The exterior vessel is made of sheet iron, and is preferably about 2½ft. high, and may be of various diameters, from 4in. to 12in. A screwed cap is at the upper end, through which is introduced the alkaline carbonate solution, and a tight sealed bottle containing the acid is inserted in the midst of the liquid. In the upper hollow part of the metal vessel is fixed a central ring, secured to two or more radial metallic supports projecting from the interior surface of the vessel. One of the supports is of the form of a screwed spindle, and is intended to be worked from the outside. The vessel of acid is supported within the central ring, which has several sharp studs on its inner surface to help in cracking the glass when pressure is exerted by the spindles. A screwed stuffing box is formed on the outside of the vessel to keep the neck of the spindle pressure tight. The outer end of the spindle is provided with a handle, and a slight lateral inward traverse is sufficient to crack the bottle and allow the acid to escape. A hinged forked arm is attached to the exterior of the vessel to inclose the handle and to prevent its being accidentally burned when not required. A vertical tube projects down from the upper part, and is used for the discharge of the gas given off. The inventor claims the combination of the ring and its accessory fittings with the general construction of the apparatus.—No. 2229. February 12th, 1887. 8*d.*

YARN SIZING APPARATUS.—*J. S. Sutcliffe & J. S. Smith, Bacup, Lancashire.*—The object of this invention is to obtain greater uniformity of sizing in yarn sizing machines. For this purpose the squeezing rollers are driven by means of two cone pulleys, and the speed of the rollers is altered by moving the driving belt along the pulleys. When heavy warps are passing through the machine the speed is reduced, but is increased on the passage of light warps. Two claims are made for the improvements described.—No. 1640. February 2nd, 1887. 8*d.*

STOPPER FOR BURST TUBES.—*H. T. B. Sanderson, South Shields.*—This apparatus is designed for the stopping of tubes which have been burst by external pressure, and consists of a wrought iron rod provided with stoppers at either end. The front end stopper is constructed of a screwed ferrule B, which has a collar at one end, and also of a loose washer C and a nut

D. Between the washer and collar is placed an india-rubber washer E. The back end stopper consists of two loose eccentric cones F and an eccentric nut G. Between these two parts is placed the india-rubber washer H. The two end stoppers are placed into the front end of the tube, leaving the rod A projecting out of the tube. The front stopper is then made steam tight by screwing up the nut D. The other stopper is then pushed into the tube to its proper position, and is made steam tight by screwing on the square at the front end of the rod. The objects aimed at by this invention are: To arrange operations so that the front end stopper may be made steam tight before the back end stopper is allowed to pass the fracture, and to use the front end stopper as a stuffing box for the rod until that stopper is made steam tight. The inventor makes four claims.—No. 2341. February 15th, 1887. 6*d.*

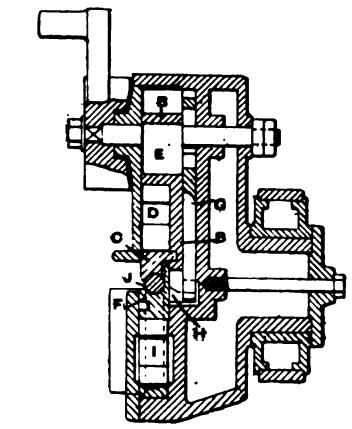
AXLE BOXES.—*A. J. Boult, London.* (*F. B. H. Bouter, Chicago, U.S.A.*)—This invention has for its object the prevention of waste of the lubricating oil. At one end of the box is an opening through which the cotton waste is introduced to the axle. At the other end of the box is the opening for the reception of the axle. The wall through which the latter opening is cut is divided transversely to the axle by a channel, which extends all round the opening. In this channel rests the sand board. In order to prevent the escape of oil through the opening in the wall and sand board, a screw is inserted through a specially tapped hole in the upper portion of the wall of the axle box. The screw is hollow, and is threaded externally, and terminates above in a closed square end, suitable for grasping with a wrench. A stem fits closely into the open end of the tube and rests with its inner end against a coiled spring, while its outer end protrudes a short distance from the tube. The tube and stem are so placed in the shell of the axle box that the outer end of the stem presses gently against the upper side of the axle, and so prevents the escape of oil. As the stem is made of soft metal, its friction does not cause any grooving of the axle, but only tends to impart to the stem a concave surface, evenly fitting with that of the axle. The inventor makes eight claims.—No. 13756. October 11th, 1887. 8*d.*

LACE MACHINES.—*A. W. Smith, Nottingham.*—The object of this invention is to provide means for regulating the tension on the beams containing yarn. A clip is formed by bending a strip of metal, of suitable dimensions, into the form of a circle, to fit the beam collar. An extension, or loop, is made opposite the two free ends of the metal strip, and the two ends are turned parallel to each other, and are provided with holes through which passes a screw bolt. A winged nut prevents the clip from cutting the beam collar, and the clip is lined with leather to insure a regular amount of friction. The clip is placed on the

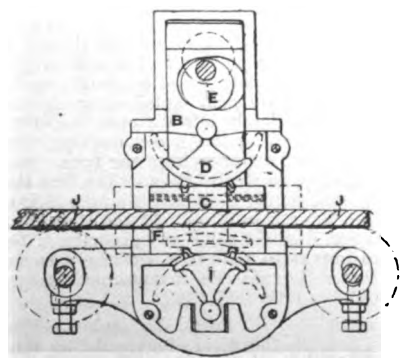
Digitized by Google

beam collar with the loop over a pin, secured to the beam bearing, and the requisite amount of tension is obtained by means of the screw. The inventor makes two claims.—No. 12968. September 24th, 1887. 6*d*.

Tension Pulleys for Spinning Machines.—*J. Wilson, Shipley, Yorkshire.*—In order to simplify the construction of pulleys, a tinned plated is placed between a pair of dies, fitted to an ordinary screw or hydraulic press. The press, when operated, blocks the plate to the configuration of the dies, and forms a flange on the circumference. The opposite side of the pulley is made in a similar manner, with a sheet of metal of less diameter than before, so that a flange of only one-eighth of an inch is formed on it. The two plates are placed together and the axle secured thereto, and the flanges on the side plates forming the circumference are soldered together. The inventor makes two claims.—No. 755. January 18th, 1887. 6*d*.



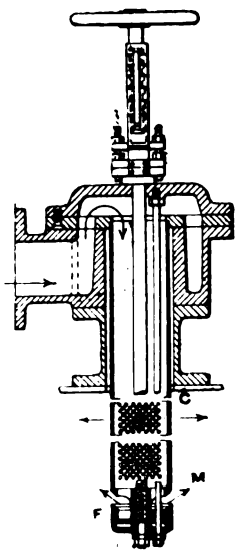
Railway Brakes.—*G. A. Boyden, Baltimore, Maryland, U.S.A.*—The improved brake is applied by the pressure of springs, and is released and controlled by the pressure of a compressed fluid supplied from the locomotive through a train pipe. On each carriage, and in communication with the train pipe, is mounted an expansible chamber preferably formed of a metal box or drum containing a flexible diaphragm. It may, however, be formed of a cylinder containing a piston. On one side of the diaphragm and pressing against it are a number of suitable springs, and the compressed fluid is admitted on the other side. The diaphragm also carries the rod by means of which the brakes are applied. The brakes are first applied by means of a hand wheel fitted on the car, and after that are under the control of the engineer. In case of a coupling pipe breaking, or the train parting, the brakes are applied at once. Nine claims are made for the improvements described.—No. 15175. November 8th, 1887. 8*d*.



Machine Tool Holder.—*D. S. Seymour, Hartford, Connecticut, U.S.A.*—The stock of the tool holder is slotted at one end, and is furnished on one side with two diagonal grooves extending across the slot. The interior of the eye bolt is shaped so as to correspond with the diagonal grooves. The eye bolt is placed in the slot in the stock, and the tool is passed through the eye and placed in either of the grooves, thus inclining one way or the other according as it is desired to use it for right or left hand work. The eye bolt is then screwed up and the tool is secured. One claim is made for the combination of the parts described—No. 14122. October 18th, 1887. 6*d*.

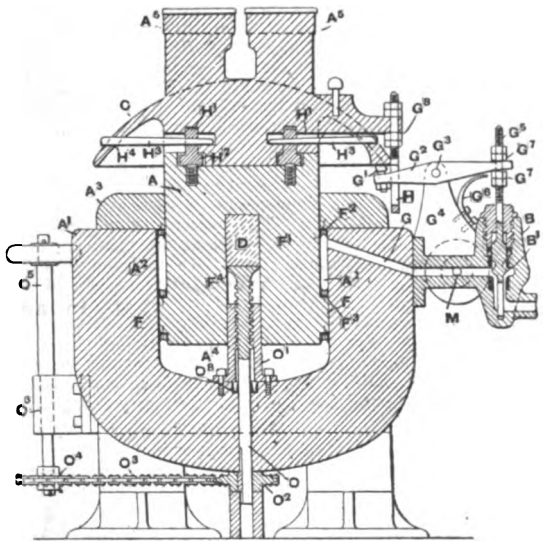
Filter Presses.—*E. A. Cowper, London.*—In a filter press constructed according to this invention, thin plates, preferably of mild steel, are employed, and great rigidity and stiffness is imparted to them by making them of a slightly domed or conical form. The plates are cut or punched from rolled sheets, and are shaped by being pressed between dies in a hydraulic press, or by other known means. It is preferred to form the plates with flat portions at their edges where the joints are made. Claim: The construction and use for a filter press of steel or wrought iron plates domed, conical, or conoidal, substantially as set forth.—No. 15238. November 8th, 1887. 4*d*.

GERMAN PATENT ABSTRACTS.



Coupling Apparatus.—*Adolph Bleichert & Co., Leipsic-Gohlis.*—This invention relates to the connection between cars and driving ropes. By turning the eccentric E, and thereby actuating the slide B, the jaws C and F are pressed against the rope J; by means of the two toothed segments D and I, the

pressure of C and F is automatically regulated according to the power transmitted by the rope. When the coupling is disconnected, the jaws C and F are brought back to their place by D and I, returning to their normal position. A sliding bar L, actuated by cams on the shaft of the eccentric, locks the jaws C and F by means of the catches H.—No. 41441. February 27th, 1887.

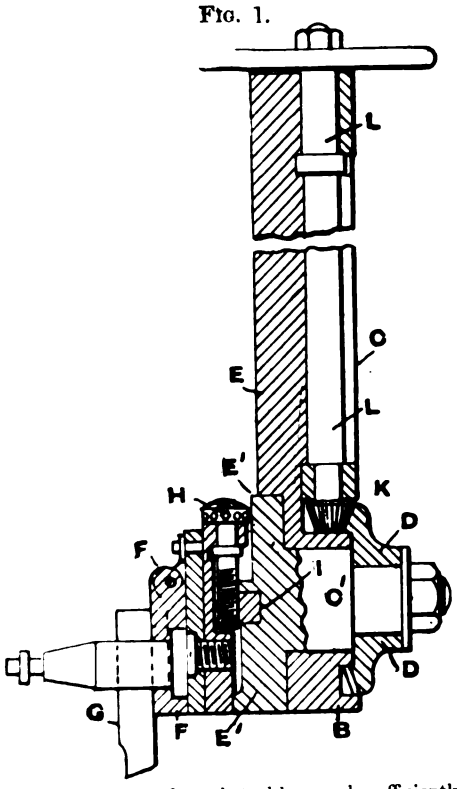


Condensers.—*Ernst Spandau, Magdeburg.*—This invention relates to an improvement of the roses used for condensers. The piston F is lowered by means of a screw as the perforations

in the rose C get choked up. When F arrives at its lowest position, that is, when all the perforations have become useless, the water is discharged through M in the shape of a bell.—No. 41464. June 1st, 1887.

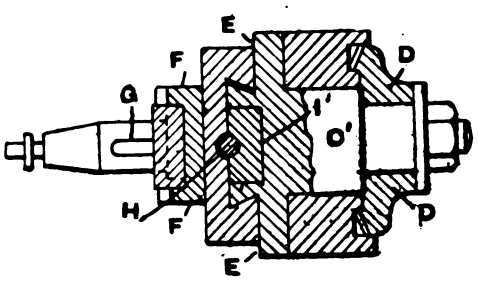
UNITED STATES PATENT ABSTRACTS.

Brick Machine.—*S. E. McGregory, St. Louis, Ohio.*—This invention introduces several improvements into the construction of a machine described in McGregory and Koch's Patent No. 332814. Some of these will be understood by reference to the annexed diagram, which represents a section of the lower hydraulic cylinder. The plunger A of the press is made to work



in the cylinder A^1; instead of relying on gravity to restore the plunger to its original position after the stroke, an arrangement is devised for accelerating its downward movement. For this purpose the upper part of the plunger is narrowed, leaving an annular space A^2 between it and the cylinder. Water is caused to enter this space through the tube G, and its action on the part F of the plunger accelerates the downward motion. The ring A^3 confines the water and concentrates the hydraulic force. The movement of the plunger serves to open and close the exhaust valve B^1 for the chamber A^2. The valve chamber B is attached to the cylinder A^2, and the water is admitted and exhausted from the same passage G. The dust protector C, before it reaches its lowest position, strikes the set screw G^1. By means of the lever G^2 and spring G^6 the valve B^1 is unseated, and it remains so until the loop H in its upward motion engages the lever G^3. The inner end of the lever is then drawn upward, and the valve B^1 is seated; at the end of its stroke the inlet valve opens by the action of a lever and admits the water through the side pipe M. The water pressure holds B^1 seated until it is unseated in the next stroke. Provision is made for cushioning by placing a spring D in the chamber F^4. The screw O supports the spring, and also serves to regulate the length of the stroke, as it can be adjusted vertically by the mechanism O^2 O^3 O^4 O^5. There are also improvements in the mould frame, in the mode of holding the moulds, and in the means of opening the exhaust valve for the lower chamber of the hydraulic cylinder, and other variations in the construction of the machine. The inventor makes forty-one claims for the improvements and their combinations.—No. 362102, dated 3rd May, 1887.

Lamps.—*B. J. M. Menge, Cincinnati, Ohio.*—The body of the lamp, which is enveloped by a cylindrical glass case, consists of two main parts, the reservoir for the oil and the apparatus for regulating the wick. The intention of the inventor is to make use of vegetable combustible matter, and in order to heat the oil before its access to the wick, the reservoir is placed at the upper part of the case, and the heated gases from the flame are made to pass up a flue which penetrates the reservoir. Two tubes support this reservoir, one of them allowing the oil to flow down to feed the lamp, and the other to admit the air necessary for combustion. The lower part of the reservoir partakes of a conical shape, thus acting as a reflector for the light. The apparatus for controlling the wick consists of a main spring, a balance wheel, and a train of wheels, which operate intermittently a trimming device and a wick-raising mechanism. The trimmer is composed of two independently pivoted limbs, each having inclined cutting faces, in order that the wick crust shall be thrown off laterally when their operation is completed. By these means the wick is snuffed and raised at the same time automatically. The inventor makes nineteen claims for the details of these improvements, together with their several combinations.—No. 373083, dated 15th November, 1887.

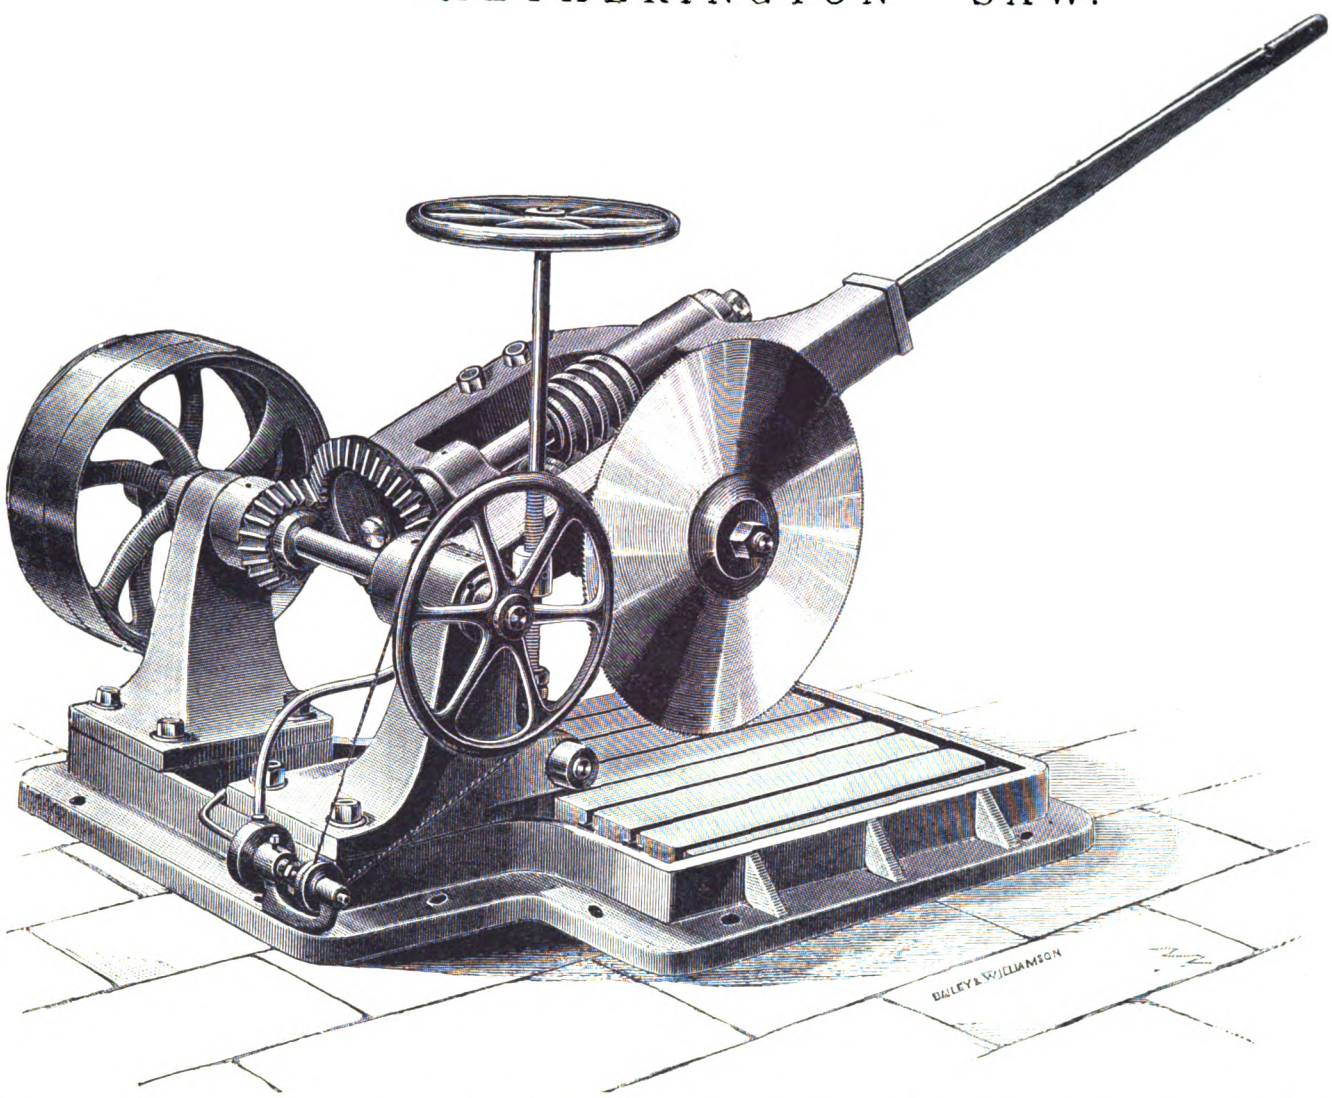


Planing Curved Surfaces.—*C. F. Geyer, Aurora, Illinois.*—The invention consists of a cutting tool intended more particularly for the planing out of the driving boxes of locomotives. The tool is applied to an ordinary planing machine, having the usual bed, cross head, and automatic feed. The Figs. 1 and 2 represent a vertical and transverse section of the tool-holding

Fig. 1.

bar respectively. E is a forged steel bar made sufficiently heavy and strong to withstand a considerable strain. At its lower end is a circular enlargement B, and at its rear a groove C. Concentric with the enlargement B is a shaft C^1, upon which is mounted a gear wheel D and a face plate E^1. The front part of this plate is shown in Fig. 2, and is of a dovetailed shape in cross section. The plate serves as a vertical guide for the tool carrier F, which holds the tool G. The tool carrier is made vertically adjustable upon the dovetailed projection by means of the screw H, which works within a half nut I set into the face plate E^1. The gear wheel D is driven by the pinion K upon the end of the shaft L, which rests within the groove at the rear of the bar E. The shaft L, and with it the gears which give rotation to the

Fig 2



face plate E^1, may be driven by hand or by ordinary feed gear wheels, and the bar E may be given a lateral movement on the cross head by the usual means. An important advantage connected with this device is that several boxes may be operated upon at one time, and thus greater accuracy is secured, and the boxes may be used interchangeably. The inventor makes four claims for these combinations.—No. 373586, dated 22nd November, 1887.

THE "HETHERINGTON" SAW.

THE "HETHERINGTON" SAW.

Our illustration represents an improved machine for sawing iron or steel bars of various sections while cold, constructed by Messrs. Hetherington & Co., engineers, Manchester. This machine is fitted with a saw 22in. diam., and it will cut round or square bars up to 5in., and channel sections up to 12in. by 6in. As will be seen, it is constructed with a planed bed plate, in which are T slots for bolting down the work, and surrounding this is a trough into which flows the soap and water used for lubricating. The saw itself is fastened to a steel spindle carried in two bearings, which are attached to the two sides of an oscillating frame. To the saw spindle is fastened between the bearings a gun metal worm wheel, into which gears a steel worm cut out of the solid and forming part of the spindle carried by bearings arranged longitudinally in the frame. The power is transmitted by means of a belt working upon fast and loose pulleys, which are carried on a cross shaft supported by two curved standards bolted to the bed plate. By means of bevel wheels, clearly shown in the illustration, the motion of the cross shaft is communicated to the worm. The inner bosses of the standards are turned so as to form trunnions, on which the saw frame is pivoted. The feed motion is effected by means of a hand lever, to which, if desired, a weight can be attached; but, on commencing, the frame is lowered by the vertical screwed spindle, on the end of which is a hand wheel. When the saw comes in contact with the work, this screw is run back sufficiently to free the frame, lock nuts being arranged to act as a stop when the saw has gone through the bar or channel section. The saw is thus prevented from cutting through the bed plate, and its range of movement limited. The lubricant is supplied by a small centrifugal pump driven from a grooved pulley on the end of the driving shaft, so that while the saw is running a plentiful and continuous stream is thrown upon it. When it is necessary to sharpen the saw, a small emery wheel can be attached so as to treat each tooth, being driven from a groove formed on the outer edge of the loose pulley, while the saw is held by a pawl, which enables it to be moved forward a tooth at a time. It will be seen that the machine is very complete, and that provision has been made for all contingencies. All the bearings are long, and ample strength is given to every part of the machine. We understand that the makers have now a large number of these machines in use under all conditions of work, and that, as the cost is reasonable, it is taking the place of other machines designed for the same class of work. It will be seen that the rate of traverse of the saw is variable, being greater where a small amount of metal has to be cut, and slower where a large area is being treated. It is claimed that in this way the saws are able to maintain a higher average speed with less damage than in the older style of machine. The circumferential velocity recommended by the makers for cutting iron or steel is 50ft. per minute, and at this speed a girder of H section 12in. by 6in., with a thickness of $\frac{11}{16}$in., may be cut in ten minutes; a similar section, but only 9½in. by 3½in., and $\frac{7}{16}$in. thick, occupying only four minutes to cut.

UNIVERSITY EXTENSION AND TECHNICAL EDUCATION.

By Henry Dyer, C.E., M.A.

I.

What is usually understood by the "University Extension Scheme" had its origin about fifteen years ago mainly through the efforts of Professor Stuart, of Cambridge, and the lecturers were as a rule graduates of that University. Naturally, therefore, the subjects selected by them for the popular classes were those which had been included in their own curriculum of study, and were thus for the most part of a literary or purely scientific nature. On the other hand, by "Technical Education" people generally understand instruction, which is chiefly of a practical nature, relating to the trades or industries of the country, and the two educational movements which are known by the above mentioned names have to a large extent been kept entirely distinct. This is not only unnecessary, but it is altogether a mistake. The education of the country must be looked upon as a whole, and its various parts made to work in harmony with each other, and not as separate, and to a certain extent antagonistic units. In his recent paper on the "University Education of the People" (*Contemporary Review*, November, 1887), Professor Garnett expressed the opinion that the relation of the university colleges to technical education constitutes an important question which will very soon demand serious attention, and he briefly indicated some of the steps which ought to be taken to enable local colleges to meet the demands of the district in which they are situated, not only for general, but also to a large extent for technical or industrial education. In this article I shall attempt some further details, and to give my proposals more definite shape, I shall suppose that they apply chiefly to the district with which I am best acquainted, viz., the West of Scotland, of which Glasgow may be looked upon as the centre. This district includes educational institutions and industries of all kinds, and if unlimited means were at our disposal might soon have a very perfect scheme of education in every department. Whatever applies to it will therefore apply to all other districts in the country, simply by omitting those parts which are not represented in those districts. The other day Professor Huxley said that he did not believe that the man lives at the present time who is competent to organise a final system of technical education of any kind, as all attempts made in that direction must for many years to come be experimental, and that we must get to success through a series of blunders. If this be true of technical education taken by itself, it must be true to a much greater extent of attempts to arrange a system which would also include general education. At the most, all that can be done for a start is to sketch in brief outline the plan of operations intended to lead up to an ideal system of education, and to leave the details to be filled up by those whose local knowledge enables them to judge fairly of the wants of the different districts.

Before we can form an adequate idea of what University Extension should mean, we must have a more complete conception of the functions of a university than that usually held. If that meaning has been more restricted than it ought to have been, it was not because the man who was the chief inspirer of the work had limited notions regarding it, but simply because the men and means at his disposal were not sufficient to fully carry them out. At the opening of University College, Dundee, a few years ago, Professor Stuart said: "This college is part of that great new educational movement which is just beginning to feel its way, so to speak, into life. Like the ancient University movement of eight hundred years ago,

it is arising, not in any one nation alone, but simultaneously throughout Europe. It is a part of the great forward, onward movement of men's minds, a step in modern civilisation; and all such steps are common to the nations. It is the gaining of one other part of human life to a thoughtfully ordered scientific whole, it is another mountain top still further to the west, touched with the slowly rising sun of human progress. And it has this inestimable characteristic, that it descends right through the masses of the whole people. This movement, in which your college has consciously taken part, is a movement in keeping with the time. These are democratic days—the days of privilege are numbered. Whatever is done must be done for the people, not for the few; and the new demand for a new scientifically ordered education comes from the great body of the people, and not only from the cultured few. It arises in great towns; it must be met in these great towns. It has all the characteristics of the new life of the age. So here, then, we must raise into existence a new class of education, a new scientifically ordered system of thought, a new faculty—the faculty of applied science—which shall not necessarily follow on any of the old lines, but shall shape its existence and its form by the answer to the all important question, What do the people need?"

If educational authorities had been in the habit of asking themselves this question, we should not now require to consider the necessity of re-organising all our teaching institutions. It is a sad commentary on our whole system of education when we reflect on the fact that improvement in those institutions has as a rule been forced upon them from without, and that the men who ought to have led public opinion were content to allow the great stream of national progress to flow past, and leave the institutions under their charge undisturbed in their sluggishness.

What do the people need? Certainly not a curriculum three hundred years old, which, however well suited to train priests, doctors, and lawyers of that period, does not at all meet the wants of the present day. They need to be trained as men and citizens, and the highest institutions should therefore not only be able to afford them a good liberal education, but also whatever professional training was necessary. In its higher departments, at any rate, what goes by the name of technical education is exactly the same in kind as the older education of doctors (the only one which has kept up approximately with the times), and should be given by the same class of institutions. Students of medicine attend lectures on scientific subjects and on their applications to human anatomy, physiology and surgery; they work experiments in laboratories, and make drawings of the various subjects they study, and they obtain the more practical part of their knowledge in hospitals and private practice. What is wanted by engineers and manufacturers is exactly of the same nature, viz., a knowledge of the principles of mathematical and physical science and their applications to industrial problems, the ability to put on paper the results of their calculations and study, supplemented by experimental work in laboratories. Like the doctors, the practical part of their training should be obtained outside the College walls under the conditions of everyday life, and not with the artificial surroundings of a toy workshop or manufactory.

Professor Garnett, in his paper, points out a distinction which is very often forgotten, and shows wherein lies the difference between a technical school and a trade school. He says (*Contemporary Review*, November, 1887, page 651): "In a trade school students learn precisely what they would learn in a workshop. Such schools exist in France and America and elsewhere; and in the trades which require comparatively little skill and inexpensive plant, there are many examples in connection with refuges, reformatories, and similar institutions in this country. The technical school is intended, not to take the place of the workshop, but to supplement its teaching. In the workshop the apprentice is taught to imitate; in the technical school he should be taught to think. In the workshop he learns methods; in the technical school he should be taught the corresponding reasons. In the workshop he performs the same operation repeatedly and under the same conditions until he acquires manual dexterity. In the technical school, if he repeat an operation, he varies the conditions so as to acquire practical knowledge, and be prepared for any emergency that may arise." The majority of those who talk and write about technical education never get beyond the idea of a certain amount of manual training, combined with the minimum of scientific knowledge required to enable the students to understand the operations they perform, and in its strictly etymological sense this meaning may be correct, but it shows the absurdity of allowing oneself to be bound by words instead of looking at the facts of the case. It might be an advantage if we abolished the use of the term "technical education" altogether, and included the higher and scientific parts of it in the ordinary institutions for general and professional education, and relegated the practical parts to trades schools. On the Continent, and in the United States of America, a considerable number of trades schools have been inaugurated; but as a rule they are kept quite distinct from what are usually called technical institutions. In the latter country there has been a considerable amount of discussion on the subject, and the following extract shows how the question is viewed by different types of educationists: "The phrase 'industrial education' may have and has acquired two entirely distinct meanings. As understood by one party, it means the kind of education that is intended to foster industrial skill, and to fit the pupil, while at school, for the industrial pursuits of later life. Perhaps the majority of those who insist on the importance of industrial education in public schools, and who are urging its adoption, use the phrase in this sense. But there is a totally different sense in which the phrase 'industrial education' may be understood; not that education shall be made subservient to industrial success, but that the acquisition of industrial skill shall be a means of promoting the general education of the pupil; that the education of the hand shall be a means of more efficaciously educating the brain. It is in this latter sense, in which labour is regarded as a means of mental development, that industrial education is understood by the most enlightened of its advocates. They are well aware that to introduce a trade into the school is to degrade the school; that to take away from the young the time that should be dedicated to the elements of general culture, and devote it to training them in a special aptitude, however useful later on, is to impair the humanity of the child. They desire nothing of this sort, and they ask that a workshop be connected with every school for no other reason than that for which a chemical laboratory is connected with every college. There are thus two antagonistic parties whose watchword 'industrial education' has alike become. The one seeks to make the mass of mankind more machine-like than they already are, though with the proviso that they shall be made more perfect machines, more skilful to increase wealth, and to feed the channels of the manufacturers' profits. The other party, standing at the opposite pole of thought, seeks rather to elevate the masses, to more completely develop the humanity of the young, and looks upon technical and art education in the school as a novel and admirable means for achieving this result."—Prof. Felix Adler, *Princeton Review*, March, 1883.

(To be continued.)

NOTES ON SCREWING APPLIANCES.

I.

TAPS.—There are few tools so universally employed as screw taps; they are to be found in many varieties in the workshops of every engineer, and in fact in every workshop or mill where metals are manipulated or machinery used. Yet although their present form is based on the results of long experience, it is by no means an uncommon occurrence to find taps of such mechanically bad design as to necessitate the expenditure of an unnecessarily large amount of power in the very simple operation of, say, tapping a hole. Nothing appears easier than to do this and to do it properly, and indeed so easy is it that the very qualities essential to a really good tap are frequently lost sight of even by some firms with whom the making of taps is a specialty, and they are often completely ignored by a few old fashioned engineering works who year after year make their own taps in a very roundabout and clumsy way, although taps of much better design and capable of doing more work can be bought at less than half of what the "home made" taps have cost. Originally, taps were made by screwing a rod and then filing three or four flats on it to form the cutting edges. The angles of the cutting edges were thus necessarily obtuse, and the action of the tap was one of scraping and abrasion. Taps of this kind are still to be found in use, owing either to ignorance or indifference on the part of those who use them, as the force required to use them is very excessive, and the work done by them cannot be of the best. The qualities essential to a good tap are rather more numerous than would appear at first sight, and may be summed up as follows: (1) It must be of the length that has been found most convenient for general work, and as tap makers are all agreed on this dimension, no remarks are necessary; (2) the diameter of the screwed part must be such that the hole tapped by it is large enough to allow a bolt of standard size to enter easily, and to do this the tap must be from $\frac{2}{1000}$in. to $\frac{5}{1000}$in. larger than the gauge; (3) the tap must cut a thread with the least possible expenditure of power, and in such a way that the surface of the thread is smooth and not, as often appears when bad taps are used, rough and torn; both these conditions are dependent on the condition of the cutting edge, and on the form and size of groove; the former is also dependent on the way the thread of the tap is "backed off," but this will be fully discussed later on under the head of grooving. (4) The tap must be capable of withdrawal with a very much smaller force than that required to tap the hole. This may appear to some as an unnecessary condition, since it is generally considered that the tap can never need anything like the same force to withdraw it as to cut the thread, but nevertheless such is sometimes the fact. The fault is in the size and form of the grooves, and not unfrequently in the backing off, and will be considered under those heads.

There are, as every engineering reader well knows, several kinds of taps, viz., working taps, machine taps, plug and full sized master taps, gas and gas master taps, fine and square thread, boiler stay taps, &c. The best proportions of all but stay taps have been settled by long experience, and there is very little variation in the dimensions now adopted by all the best English makers, and given in the accompanying tables.

SCREW THREADS.—Until about 1840 almost every engineering establishment in the country had its own rules for the proportions of screw threads, which gave rise to considerable inconvenience in the provision for repairs, and rendered them expensive and imperfect, owing to the fact that it was not at all an easy matter to measure accurately the pitches of threads on the bolts requiring renewal, and thus repairs were imperfect and many bolts weakened by having badly fitting nuts if the latter were used again. Great waste was occasioned when old nuts had to be replaced by new ones fitting the new bolts accurately. Sir Joseph Whitworth was the first to recognise the importance of this difficulty, and to take steps to reduce the various practices of engineers to one common standard; and after a few years, as is well known, his rules for threads became the only recognised standard for this country. The conditions of a properly formed thread are power, strength, and durability, and their essential requisites are pitch, depth, and form; the power required for closing two pieces of mechanism together determines the pitch, which, for a given diameter of bolt, determines the angle of the inclined plane of the thread round the surface of the bolt. The form determines the direction in which the force acts, and durability depends chiefly on the depth of thread. A square thread has the advantage as regards power, because the resultant of the force applied is in the direction of the axis, but it is weaker than a V thread of the same pitch. A fine thread gains in power, but loses in strength, and an increased depth of thread obviously weakens the bolt; hence it is apparent that any thread made to fulfil one condition is defective as regards the other two conditions, and a mean must be

Digitized by Google

made so as to give the greatest satisfaction as regards the three conditions of a good thread taken collectively. It is a matter which cannot be calculated, but is acquired by experience, and Whitworth in forming his scale collected all the best forms of other engineers, and taking a mean of them produced what is now universally known as the "Whitworth thread," and used to the almost total exclusion of every other form except in America, which has a system of its own. It is important to remark that the proportion of pitch to diameter varies with nearly every size of bolt; but the angle is in all cases 55°, and the top and bottom of the thread is rounded off to one-sixth of the depth, in order to preserve the thread as much as possible from injury, so that the actual depth of thread is ·64 of the pitch. The American system of screw threads differs from ours in the fact that the angle of thread is 60°, the top and bottom being cut down flat to one-sixth the depth. The pitch of threads is the same as our own with the exception of ½in., 1⅝in., and 1¾in. bolts, which have 13, 5½, and 5 threads per inch respectively.

Working Taps.—These are made in sets of three, viz., taper, second, and plug; each being made of convenient length. The taper tap is turned taper from the point to the sixth thread from the top, and the diameter at the point is the diameter at bottom of thread; thus there are six full threads at the top and no thread at all at the extreme point of the taper tap; it is backed off by the file on the taper part only. The taper of the taper tap should not be more than to the bottom of the thread, or it is liable to be used in holes which are too small, at the risk of breaking the tap. It is also of importance to avoid excessive backing off, especially if the backing off is done by the chaser as in some cases, as the tap is liable to "wobble" in the hole and tap it too large, and also to wedge fast the cuttings when being drawn out. The second tap is rounded off from the point (where the diameter is the same as that of the taper tap) to the sixth thread from the point, the remainder of the screwed part having a full thread, and the taper part only is backed off by the file. The plug tap has a full thread down to the point, and is not backed off at all.

Machine Taps.—These taps are used almost exclusively for nut tapping machines. There is only one of each size instead of three, as in the the case of working taps, and when in use the tap is passed right through the nut. The screwed part has until recently been made much longer than for working taps, but of late the best firms have reduced the length considerably. The old fashioned machine tap is screwed parallel and tapered the same as a taper working tap, but with those having a reduced length of screwing the thread is screwed taper from the point to the sixth thread from the top and then parallel; the object of the taper screwing is to equalise the strain on the machine; the diameter at the point of the new tap is the diameter at bottom of thread as given in the table, and the thread is then cut to half its depth at the point by a chaser on a taper screw cutting lathe, and the thread backed off by a file in the usual way for taper taps. The effect of this alteration has been to equalise the wear and increase the life of the tap, and to diminish the time required for tapping a nut.

Plug Master Taps.—Only one tap of this kind is supplied for each size, and that, as its name denotes, is not used for roughing out, but simply for finishing the thread. Plug masters are used for finishing the thread in solid dies, such as are used for screw stocks and screwing machines, and also as a "hob" for finishing the threads on "chasers" used with screw cutting and hand lathes. The thread is parallel from top to bottom, and is not backed off at all. The grooves are more numerous and smaller than for working and machine taps, so that they may be used for re-cutting solid dies, where it is evident that if the top grooves were wide and few in number they would be constantly interfering with the grooves in the die, and a round hole of accurate size could not be tapped. It would also be inconvenient if not impracticable to cut a chaser on a hob with wide grooves, and indeed the taps have so little work to do that wide grooves are quite unnecessary.

Full Master Taps.—As in the case of plug master taps, only one of each size of full master taps is made, and these are similar in every respect to the plug masters. The diameter of a full master is, however, exactly twice the depth of the thread greater than the size marked on the tap; for instance, a 1in. full master is 1in. diam. at the bottom of the thread. They are used for cutting the threads of dies in guide screw stocks, and in the die box of most screwing machines. The object of using this tap in the first case is to have the points of the thread on the dies at the proper inclination for tracing a thread of accurate pitch on the bolt, and it is obvious that if any other size of tap than the full master were used, the inclination of the thread to the axis traced on the bolt would be either too great or too small, and a thread of incorrect pitch would be cut in the first part of the operation. To see this point clearly, it is only necessary to remember that for any given number of threads to the inch the pitch is quicker and the inclination of the thread greater at the bottom than at the top of the thread, as shown by the diagram Fig. 4, on the next page.

In Fig. 4, let A B represent the circumference of a common tap, say 1in. diam. at the top of the thread, and B C the pitch of that thread, therefore A C is the inclination of the top of the thread to the axis of the bolt. The circumference at the bottom of the thread is A D (only 2·637in.), and A E the inclination of the bottom

Digitized by Google

LOGGING IN CANADA.

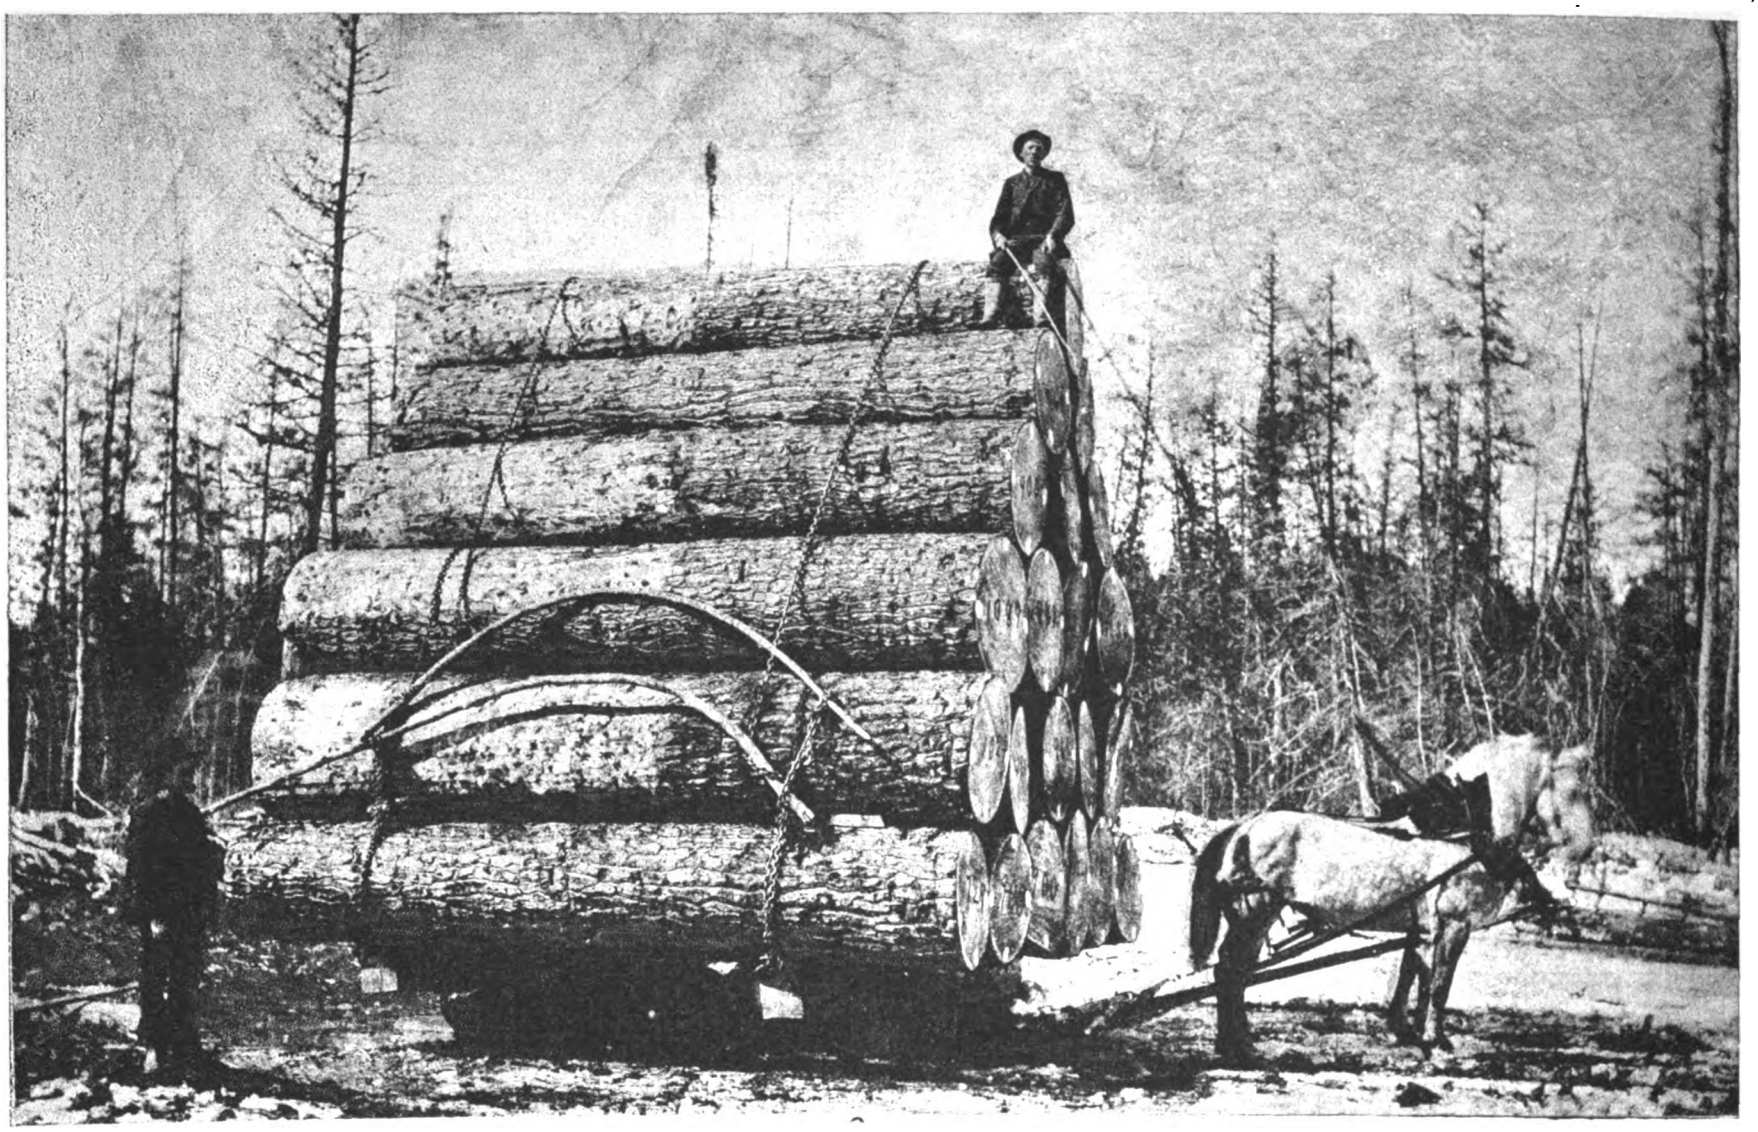

FIG. 5.—A LOADED SLEIGH.

of the thread to the axis. This being the case, it is manifest that if the dies of a guide screw stock were cut by a plug master, A E would represent the inclination of the thread traced on the surface of a 1in. bolt at the beginning of the operation, and therefore the pitch of that thread would be ·149in. As the thread is cut deeper in the bolt its pitch would be gradually reduced to ·125in., the resulting thread being slightly imperfect,

FIG. 4.

although on an ordinary bolt no defect might be observed from this cause. The question of cutting the dies of a screwing machine with a full master tap will be referred to at a later stage.

GAS TAPS.—These taps are used for iron pipe couplings and for roughing out the solid dies for screwing iron pipes. The diameter at the top of thread is twice the thickness of the pipe greater than the standard size marked on the tap, that is, equal to the outside diameter of a gas pipe the bore of which is the size marked on the tap. Two taps of each size are used; these are called taper and plug, but they really correspond to the taper and second of ordinary taps as regards the backing off; the grooves are more numerous than in ordinary taps, but their form should be the same.

(To be continued.)

NEW CORLISS ENGINE.—A modification of the Corliss engine has been lately built by a firm in Elmira, New York. The valves are arranged on the Corliss plan, but the governor is what is known as a shaft governor, and as the motion is all positive, releasing gear and dash pots are not necessary. The engine, which is very economical, is for high speeds, and the regulation is very good.

LOGGING IN CANADA.

III.

(Continued from page 55.)

THE conveyance of the logs from the "roll-ways" to the river is comparatively straightforward work. For rapidly as these forest thoroughfares are constructed, they are nevertheless easy to traverse, as the frozen snow affords a firm and smooth surface for the sleighs to travel over. These roughly constructed vehicles are loaded with as much timber as a pair of horses can conveniently draw, and sometimes rather more; the amount being regulated by the length of the journey to the river. Towards the end of the season, a great deal of rivalry exists between the different teamsters, as to who can successfully convey the largest load in one journey with his pair of horses, and Fig. 5, taken from a photograph, gives an idea of the extent to which these sleighs are laden when a competition of this sort is on. The aggregate quantity of timber in this case amounted to 10,270ft. inch board measurement. The part of the frozen river selected for depositing the logs upon presents a unique appearance when the time approaches for the thaw to set in (which is about the month of April). The vast accumulation of timber, to one who sees it for the first time, is astounding, enabling him to appreciate, in a manner that would otherwise be impossible, the extent of the work which has been done during the previous five or six months by the industrious gangs of woodmen scattered about in the neighbourhood. He sees a space, which is in reality the width of the river, completely covered with logs piled up between two banks, and reaching, perhaps, as far as the eye can see in either direction—the river itself being entirely hidden from view. As the logs arrive they are rolled on to the ice, and stacked one above the other until they attain the height of the banks (sometimes 40ft. or 50ft.) on either side of the stream. These "log jams," as they are called, often contain as many as from three to four hundred thousand logs, and have been known to extend over a length of two miles. The illustration (Fig. 6) represents a "jam" of considerable proportions, and although the timber is not piled to anything like the above mentioned height, in this case the estimated amount contained in it is over 21,000,000ft. The river has to be dammed above the "log jam" in order to collect a sufficient head of water to displace the mass of timber below it; for the stream is never strong enough to effect this without artificial assistance, and even were it otherwise it would be policy to force the stream as much as possible, as the work of the wood is thus much more quickly carried out. So that, although these dams are very expensive, and sometimes difficult to build, it is found more economical to construct them, than to incur any delay in the log driving.

When the thaw has fairly set in, the ice given way, and a sufficient head of water has accumulated above the dam, the sluice gates are opened, and the flood forces its way through the piled up logs, carrying some of them with it in its onward course, and loosening up the whole structure. At the same time a large staff of "log drivers," armed with peaveys and canthooks, are stationed in suitable positions for the purpose of further detaching the logs from the main body, and setting them floating down the stream. This work is fraught with great danger, as it is next to impossible to calculate with nicety to what extent the logs will help themselves, and consequently it not unfrequently happens that men are standing on the top of a pile, when suddenly, being undermined by the stream, it will collapse, and crush them to death, or severely injure them. In fact, all through the "wood butcher's" trade (as the American vernacular has it) accidents are very numerous; so much so, that the lumberman's hospital is an important feature in the logging industry, and it is satisfactory to learn that in America a movement has recently been set on foot with a view to connecting hospitals in different districts, so that a yearly ticket, which hitherto would only have admitted the holder to the local hospital, becomes available for any other belonging to the association. The

Digitized by Google

LOGGING IN CANADA.

FIG. 6.—A LOG JAM.

advantage of such a system to the loggers, who are liable to be constantly on the move, is apparent. Already we hear that seventy hospitals have joined the association, situated at intervals right across the Continent, from the Atlantic to the Pacific.

To return, however, to the subject of log driving, the principal tools used for this are the "peavey," the landing hook, and the pike pole, illustrated in Fig. 7 by A, B, and C respectively. The first two of these, it will be seen, are variations of the canthook, the flat surface at the end of which is replaced in the case of the peavey by a sharp spike, for the purpose of getting a better hold; and with the landing hook by a sort of chisel edge, which bites the rough surface of the log as it is being drawn in. The pike poles are about 10ft. long, and mainly used for guiding the floating logs.

In the case of a large jam, it becomes necessary to repeat the floods, or "freshets," as they are usually styled, a great number of times before the logs are all started; and although good management and skill on the part of the men is a necessary feature in effecting the rapid disintegration of a log jam, luck has also a great deal to do with it. As soon as the jam is broken up, the log drivers follow the timber along the banks of the river, with a view to preventing the logs from forming another jam on their own account, which they would most assuredly do if those which got stopped in the windings of the river and caught against obstacles were not promptly set going again by the men. To do this, it is often necessary to get into the middle of the stream, the men walking along the intervening logs as they travel down. This feat requires a considerable amount of skill, and it is wonderful to watch the ease with which a man accustomed to this mode of journeying on the water, can get along. It is no unusual thing to see one of these men balancing himself on a round log as it is floating down the stream, and steering his course with the aid of a pike pole, with every appearance of being quite at ease, and without fear of being turned over. The spiked boots which the men wear materially assist them to maintain a firm footing.

The period of log driving is a time by no means devoid of anxiety to the proprietor. The state of the river being very dependent on climatic influences, it is important for him to have favourable weather. A dry season will cause several weeks' delay in the arrival of the logs, and until they arrive the saw mills must be kept shut. In some cases it becomes impossible to convey the logs at all,

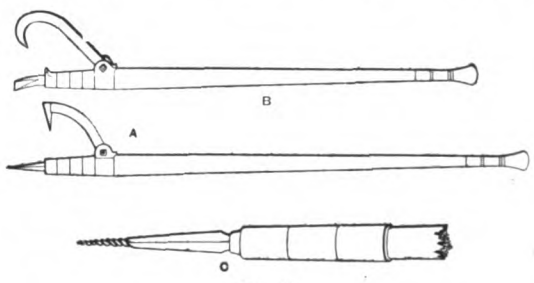

FIG. 7.

under which circumstances the financial losses are very heavy indeed. When the river is low and sluggish, the exertions of the log drivers do not suffice to keep the timber on the move without constructing fresh dams behind the logs from time to time as they go down. The distance between these dams varies naturally very much according to the nature of the stream. Under unfavourable circumstances, it may be necessary to make them every two or three miles, and when it is borne in mind that the length of a drive is sometimes as much as one hundred miles, the delay and expense of damming is apparent. With reasonable luck and good management, it is possible to move 1,000,000ft. (board measure) of logs at each freshet. According to the number of logs in a stream, the number of hands employed in driving varies; but the "crews," as a rule, consist of from 50 to 150 men. Their wages run from $\$1\frac{1}{2}$ to $\$2$ a day—in addition to which their food is found—which, although higher than those of the forest hands, are by no means excessive, as the labour of log driving is no less arduous and decidedly more dangerous than log making. A hundred mile log drive under favourable circumstances, might cost about 50 or 60 cents per 1000ft.; but this, of course, is subject to considerable variations, for reasons above explained. The timber is so rapidly receding before the inroads of the axe, that every year the length of the log drives increases considerably, as it is necessary to go farther up the country to fell. Naturally enough the Canadian lumberman follows up the courses of the best waterways on his "limit," and so far he has been able to get timber within practical sleighing distance of a suitable river, the province of Ontario being one of the best watered districts in the world; but there must come a time when he will have to follow the lead of his American neighbours, who, having pushed their operations so far, are often obliged to look for their timber now in parts of the country where there are no streams in the vicinity, and who consequently are obliged to construct railways expressly for log traffic, which system, though expensive, insures a very regular delivery, and saves a great deal of time.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 24th January, 1888.

The Iron Market.—The tone of the iron market is strong, and the aspect of affairs generally encouraging. The demand steadily increases, and prices are very firm all round. All works are now well provided with orders. The latest reports received from the provinces are characterised by a cheerful tone. It is admitted everywhere that the situation daily grows stronger, and that the outlook for the current year is far brighter than seemed possible at the beginning of December. At a meeting of the rolled wire manufacturers held during the week, the terms of the proposed syndicate were signed. The association is to remain in existence three years. The wire nail makers have also held a meeting to fix a scale of prices. In anticipation of a considerable advance in these classes of goods, a large amount of buying has taken place this week. The scarcity of pig iron in Belgium has occasioned great activity in the Longwy district, from which Belgian manufacturers are now drawing large supplies of crude iron.

The Metal Market.—The expected reaction seems to have set in. There is little genuine business in copper, consumers refraining from buying more than the quantity absolutely necessary to enable them to continue their operations from day to day, and speculators have apparently exhausted their means of forcing up and maintaining prices. A heavy fall has to be chronicled this week, Chili bars being now quoted fully £5 a ton lower. The reaction can hardly fail to involve tin, which is far above its true value in the market. It is difficult to understand how it has held its position so long, for the abnormal prices now current cannot be justified by the state of the stocks in hand. These, including the quantity afloat, amounted at the end of the year, for England, Holland, and America, to 15,576 tons, against 14,595 at the end of November, and against 12,236 tons on 31st December, 1886. Lead is quiet. Spelter is still in strong demand for consumption. Prices remain unaltered.

Distribution of Motive Power by Compressed Air.—M. Victor Popp is making good progress with his system of distributing compressed air for motive power purposes. The works for compressing the air in the Rue St. Fargeau, at Ménilmontant, are of considerable magnitude. They cover an area of 15,000 square metres, of which an extent of 2000 metres is roofed over. There are already fixed and in operation seven steam engines of 400 h.p. and two of 100 h.p. each, a total of 3000 h.p. The conduits have already been laid over the whole area comprised between the line of the Boulevards and the Rue de Rivoli. These are sometimes laid in trenches cut for the purpose, and sometimes in the sewers. The total length of pipes laid was, at the end of last December, a little over thirty miles. This source of power is used for working electric light machinery in a large number of establishments, among which may be mentioned the Café Americain, the Café de Paris, the Café Anglais, the offices of the *Figaro*, and the Jardin d'Hiver.

The Universal Exhibition.—As it is still commonly believed that exhibitors at the Exposition Universelle will have to pay a rent for the space occupied by their goods, the authorities have publicly announced, for the third time, that no such charge will be made. Exhibitors will have to pay their share, that is, proportionally to the space they occupy, of the costs of the installation, and the decoration and care taking of the building. The chief director has determined the general types of the installation for each group, which, while allowing a wide scope for variations in the decorations, will entail on the exhibitors much less expense than they were called upon to bear in 1878. The Eiffel Tower, the erection of which is being pushed on without intermission night and day, Sundays and week days alike, has now reached a height of 50 metres, where the first floor, to be used as a restaurant, is being constructed.

Prize for Pottery.—The Société Industrielle of Amiens has offered a prize of money and a gold medal to any French potter who shall succeed in making earthenware sewage pipes of a quality equal to those manufactured by Doulton & Co., of London.

BERLIN, 23rd January, 1888.

The Iron Market.—The policy of syndicating trades to obtain excessively high prices does not seem to be an unmixed blessing to the German iron trade, and voices are raised here and there in condemnation of an artificial state of things under which exporters are beginning to lose their business. As matters at present stand, finished iron makers and merchants find it very difficult to execute orders for export, since the high prices of crude iron, brought about by the syndication of the trade, are almost prohibitory. It seems likely that only those makers of finished iron will be able to compete against England and Belgium in neutral markets, who are at the same time producers of crude iron. Meanwhile the powerful weapon of the iron masters is now being turned against them. The owners of limestone quarries in the Westphalian district have formed a syndicate for the purpose of artificially forcing up the price of limestone required by the blast furnaces, the contemplated rise being in some cases as much as 80 per cent. above the present ruling price. This is strongly, though illogically, resented by the iron masters of the district, who threaten to boycott these quarries, and get their supply of limestone at whatever sacrifice in the shape of freight from other parts of Germany, until they can themselves open out new quarries in their district. The boiler explosion at the Friedenshütte is still the topic of controversy, opinions being divided as to its cause. At a recent meeting of the Silesian Boiler Insurance Society it was given out that the origin of the explosion was not, properly speaking, in the boilers at all, but that the boilers were first damaged by an explosion of the blast furnace gases, and then burst by the steam pressure inside. The Society is now trying to put pressure on the Government, in order to induce them to pass a law under which the use of blast furnace gases for boiler firing should be either prohibited or restricted. As this would be very injurious to the iron industry generally, the Verein Deutscher Eisenhüttenleute (a society composed mainly of mining and iron works engineers) intend to oppose at their next meeting the views advanced by the Silesian Boiler Insurance Society, and so prevent the passing of any law which might interfere with the present blast furnace practice.

Textiles.—Although considerable business is now being done in linen goods, reports from Saxony characterise the present position of flax spinners and weavers as by no means flourishing. The prices of linen goods of medium and better qualities are depressed, and the demand is much smaller than for the coarser kinds, resulting in a displacement of this industry which is prejudicial to the manufacturers, who have hitherto mostly produced the better kind of goods. The evil is aggravated by the fact that the Russian flax crop of last year was insufficient, and therefore prices ruled rather higher than usual. As a consequence, even large spinners are at present not able to make anything like the profit they were accustomed to. Efforts are now being made to render the trade independent of the supply of Russian flax, and several agriculturists are now trying to revive the culture of flax in Saxony, which in previous years was very flourishing. In the Rhine districts the textile business is improving, and although there is little doing in woollen cloths, worsteds are in good demand. Plush and upholstery goods are also brisk, and a good trade is being done in silk and half silk piece goods; velvets, however, are rather dull. Brussels and other carpets are in fair demand, at remunerative prices. A good trade is also being done in fabrics containing india-rubber, with the exception of elastic sides for boots, in which English competition is almost forcing the home article out of the market.

Electric Lighting in Germany.—According to the presidential address of Dr. von Stephan at the Berlin Society of Electricians, there are at present in use throughout Germany 15,000 arc lamps and 170,000 glow lamps, supplied with current from about 4000 dynamos. Dr. von Stephan estimates that an arc lamp requires on an average ¾ h.p. and a glow lamp ⅛ h.p. On this basis the total horse power employed in electric lighting throughout Germany amounts to 30,000 h.p. The Berlin gas works have also recently collected statistics regarding the extent to which the electric light is introduced in this town. It appears that 1554 arc lamps, 22,363 glow lamps, and 333 dynamos are installed. The town authorities are now negotiating for a new contract with the Electricity Supply Works, under which the cost of installation for glow lamps would be diminished by 18 per cent., and that for arc lights by 27 per cent., as compared with the prices at present charged, whilst the company undertake to pay a fine in case of failure or delay in putting up an installation. When the installation is put up to the order of the town authorities a fine of £2. 10s. for every day's delay will be imposed, whilst for non-delivery of current to private consumers within four weeks after the installation is put up the fine is £1 per day. The old market in this town was one of the first places lighted by arc lamps, but the installation has not proved very successful. The lamps were grouped in parallel series of two, and in some cases the conductor was iron wire. The buildings are very scattered, and supervision was not easy, consequently breakdowns were of frequent occurrence. Now that the municipality have determined to erect new markets in the various suburbs of this town, they propose to light these by gas. It is, however, likely that better counsels will prevail, and that the Corporation will adopt arc lamp installations where the lamps are in single parallel, and the potential is maintained at 65 volts.

VIENNA, 23rd January, 1888.

The Iron Market.—Owing to continual interruptions of traffic, due to snowstorms and the inclement weather, very little business has taken place in the iron market, and it has been impossible for the syndicated works to fix their prices for the current quarter. It is hoped that a settlement may be come to during the present week, at prices slightly higher than those ruling before Christmas. Business in the western part of the empire might be described as rather languid during the past week, whilst in Hungary the market was absolutely depressed. This is to a certain extent due to the want of decision displayed by Hungarian iron masters in the syndicate movement. Their deliberations are kept private, and dealers are therefore loath to enter into large transactions before they know what policy will be pursued by producers. A very important contract has just been concluded, under the sanction of the Minister of Commerce, between the Government railways and the Austrian syndicate of rail makers, under which the whole requirements of the State lines for rails during the next five years have been secured at the price of 96fl. per net ton, or say about £7. 10s. per ton, which is the lowest price on record. The contract stipulates for a further reduction of prices if Glasgow warrants should drop below a certain limit, whereas no increase of price will be allowed, however high Glasgow warrants may rise. The total quantity of rails estimated for renewals and extension of lines, during the next five years, is a little over 100,000 tons, and that of fish plates, bolts, and other accessories, about 10,000 tons.

The Defective Boilers at the Vienna Installation.—Now that all the hubbub about the failure at the Vienna Opera has subsided, and the financial responsibility has been settled in the right quarter, it is possible to survey the situation impartially. English readers are hardly able to conceive the amount of vehement vituperation which in a case like this is poured forth day after day in the columns of our newspapers, whilst at the same time the editors refuse to admit any letter written by an incriminated person in vindication of his own rights, or even as a mere statement of facts. The boilers for the installation were originally designed for Mr. Crompton by Mr. Wilson Hartnell, of Leeds, and would have been built in England had it not been for the intervention of our Minister, Count Taaffe, who imposed the condition that they should be built in Austria. They were consequently ordered from the Witkowitz Works, financed by the Rothschilds; and notwithstanding that the specification was drawn up in the most stringent manner, the work was done with complete disregard of the specification. Immediately upon delivery leaks began to show, and Mr. Crompton refused to accept these boilers. The makers patched them up for a time, but without permanent success. The boilers were then removed, and temporary locomotive boilers were put in, the time occupied by the change being only nine days. Since then the installation has been running without a hitch, and so far the difficulties are over; but then came the sequel as to who was to blame. It was first proposed to settle the case by arbitration, the arbitrators to consider preliminary evidence; but by some mischance they gave judgment without having examined the evidence, or looked into the workmanship of the boilers. When, subsequently, the evidence was laid before them, they withdrew their decision, and the Witkowitz Company, which had in the meantime taken the case into court in order to compel Mr. Crompton to pay for the boilers, withdrew it suddenly when the evidence of experts was brought forward. Messrs. Wilson Hartnell, MacGregor, Longridge, Professor Kennedy, and some Austrian engineers examined one of the boilers, which had been cut open for the purpose, and it was due to the opinion of these gentlemen, condemning the workmanship as utterly bad, that the Witkowitz Company proceeded to withdraw their claim, and to agree to take back their defective boilers, making no charge for them; to pay for the labour and freight in replacing them by new ones, to pay the Opera fine, which amounted to upwards of £3,000, and the professional expenses of the witnesses. The total cost of the failure to the Witkowitz Company is probably upwards of £10,000.

The Vienna Electrical Laboratory.—The programme of this undertaking has just been issued by the Directors of the Technological Museum, of which the laboratory forms a recently added section. The work will be superintended by Herr Carl Schlenk, and is to embrace experimental investigations of dynamos as regards output, power consumed, efficiency, and other matters; investigations and reports on executed installations for lighting, power, or chemical purposes, photometry of arc and glow lamps, calibration of measuring instruments, and investigations of primary and secondary batteries. A tariff has been fixed for the work, which will presumably be required very frequently. Thus for testing a dynamo the charge will be from £1. 4s. to £4, according to size of machine; for testing a glow lamp, 16s. to £1. 4s.; arc lamp, £1. 4s. to £1. 12s.; calibration of instruments, 5s. to £1. 12s. Members of the Museum obtain a discount of 25 per cent. off these charges. Where the work is of special nature or for outside work the charge is to be agreed upon beforehand. These fees are levied primarily with the object of covering working expenses. Any surplus is to be equally divided between the exchequer of the Museum and the staff of the laboratory.

BRUSSELS, 24th January, 1888.

The Coal Market.—Coke and coal for industrial purposes continue firm, with a tendency to rise. The demand for coke is greater than the supply. At Charleroi dross is quoted at 3s. 9d. to 4s.; small coal at 4s. 7d. to 5s. 9d.; cobbles at 13s. 7d. to 15s. 2d.; and unscreened household coal at 8s. 5d. to 10s. Owing to several blast furnaces in the Mons district having been re-lighted, fuel for metallurgical purposes is scarcer than before. The stocks of coal in hand are very much smaller than at the same period of 1887 and 1886. At Liège the situation is similar, and the prospects of the trade promising.

The Metal Market.—Some of the rolling mills and engineering works are now less busy. A fall has taken place in the price of certain metals, and tin is quoted at £158 to £160; copper ingots at £84; spelter at £22; and lead at £15. 12s. Luxemburg pig is quoted at 37s. 9d. free on rail. The Athus works decline to contract at 36s. for the second quarter of the year. Foundry pig is firm at 38s. 4d. to 39s. 2d. for No. 5. In view of the general

Digitized by Google

tendency of iron in Europe to advance, we may expect a rise here soon. The second tenders for the purchase of Rumelange blast furnaces have resulted in the Liège Crédit Général and the Bank of Liège acquiring one half, and the Bank of Brussels the other half, for the total sum of £132,222. The statement which has been made here that Krupp will manufacture a portion of the projectiles ordered by the Belgian Government at Charleroi, is a mere rumour, and is not based upon any tangible facts.

Glass Works.—The market has been very quiet for some time; fewer orders are received, and stocks are large. At the last meeting of the glass makers' committee, it was decided to maintain the prices fixed by the convention.

The Brussels Exhibition of 1888.—Progress is being made abroad with a view to participation in this exhibition. France will take part in it officially, and a committee has been appointed, of which the Minister of Commerce is president, and M. Bergé vice-president; Messrs. Casalonga and Estor-Mortier are the agents general. From Manchester, various buildings are being sent from the late exhibition for the British section. Collections of minerals and chemicals are being made in Germany, and there will also be sent from that country wines, beers, and spirits. The Belgian Government reserves a large space for home manufacturers and merchants, to whom room will be given at half the official rate. The buildings are still in a backward state.

The Lighting of the Town.—An important change has been made in the organisation of the management of the lighting of the town, M. Aerts, manager of the gas works, having been appointed surveyor of public lighting and gas mains in place of M. Wybauw, who takes charge of the electric lighting, clocks, and telephones. At present the electric light installation of the town only comprises the generating station at the gas works, from which the Theatre de la Monnaie, the Grand Place, and the Theatre du Parc are supplied. It is, however, probable that the municipality will favour a project of erecting an electric light station in the centre of the town, which would serve the principal restaurants, cafés, and some public buildings. Negotiations to this effect have been commenced with the Société Industrielle of Brussels.

DÜSSELDORF, 23rd January, 1888.

The Iron Market.—The relative calm which characterised the iron market in the first two weeks of the year must have been wholly due to the influence of the holiday and stock taking season, for it has given place to the same degree of activity as prevailed down to the last week of 1887. This being the case, it is not surprising that prices again show a rising tendency all round. This tendency is strengthened by favourable accounts received from the Silesian district and from abroad. Pig iron is in strong demand, forge pig being particularly sought after. Despite the recent large advance and the protests of the finished iron makers, the prices of crude iron have a decided tendency upwards, a circumstance which points to a further advance in finished produce. The effect of these high and constantly rising prices on the foreign trade is becoming very marked; imports are increasing and exports rapidly diminishing. It is surprising that under such conditions the home demand should remain brisk. The blast furnace owners' union, having made arrangements for controlling the action of the merchants, has the market now entirely in its own hands. This state of things is giving rise to some misgiving on the part of consumers. The only serious check on native producers is the import trade, which at the present high rates in the home markets is likely to afford healthy competition. The few rolled iron works which have remained outside the syndicate are now underselling the latter, and as it has been determined that the Lorraine works will not join, the competition in this direction is likely to increase. With firmly fixed rates for crude iron, all this must tend to injure the position of the finished iron and steel manufacturers. Business in bars is not very active, the foreign demand having fallen off heavily. Few transactions take place for delivery later than the end of the first quarter. Common plates and boiler plates are in strong demand. Hoops are less eagerly bought, but full prices are paid.

The Iron Industry and the Transport Question.—The question of developing the means of transport and reducing the cost of carriage is one which greatly agitates the iron industry of Western Germany at the present time. An important meeting of all the iron masters of this locality has been called for the 5th February, to consider "the future of the Rhenish-Westphalian blast furnace industry relatively to the question of ore supply." This industry is growing more and more dependent upon the *minette* ores of Lorraine, and it is contended by the blast furnace owners that their future prosperity, if not their very existence, demands a great reduction of the railway charges and the canalisation of the Moselle. The matter is of such weighty importance for the iron industry of this locality, that the meeting, which will certainly be largely attended, is awaited with some anxiety.

Flax and Yarn Markets.—Flax spinners have found but small cause for satisfaction in the business of 1887. The demand for the fine and medium numbers was generally languid, and the margin for profit dwindled away. The year closed, however, in greater activity, and the prospects have continued to improve since. The flax markets have in consequence acquired more life. Generally business is animated and prices are firm, with a rising tendency in some directions. The future of the home grown flax trade is attracting earnest attention. The partial failure of the crop in Russia of late years, and the growing ill will which shows itself in a war of tariffs between Russia and Germany, have stimulated the culture of flax in Saxony, and this movement in favour of the home trade is likely to grow. Of the imports of flax into Germany, which amounted in the first eleven months of the last year to 873,912cwt., 767,856cwt. were derived from Russia. For flax yarns there is a fairly brisk demand. The business in cotton yarns has improved within the last week. Spinners, who have plenty of orders in hand, are again firm in their demands, refusing to make the smallest concession to buyers. The tone of the market is strong and hopeful.

LILLE, 24th January, 1888.

Flax and Yarn Markets.—The market for flax offers no new features. There is still a strong and steady demand for home grown produce, at the full prices asked by sellers. Russian, too, continues to be largely dealt in, and prices are very firm. Business in yarns is fairly animated. The home demand steadily grows, and as transactions on foreign account are numerous, spinners are able to obtain more remunerative prices for their goods. Jute yarns find ready buyers, at steadily rising prices. The exports of linen and jute yarns from the port of Dunkirk in the month of December were unusually large.

The Iron Market.—Week by week the tone of the iron market grows stronger, and the outlook for the present year more encouraging. Manufacturers have determined to follow the example of their German rivals, and combine to force up prices to a remunerative level. In this determination they exhibit perfect and complete unanimity, a circumstance which has brought consumers into the market in anticipation of higher rates. Current quotations are £5. 8s. for merchant bars; but £5. 12s. will probably have to be paid before the end of next week. Some important orders from Paris have been lost to this district by underbidding on the part of manufacturers in the centre; but as there is plenty of work in hand, the circumstance has not occasioned much disquiet. Evidence of the activity prevailing in the crude iron producing district of the Meurthe-et-Moselle is afforded by the extraordinary demand for blast furnace coke. In ordinary times, the greater part of this fuel is derived from this locality; but our coke manufacturers are now unable to meet the demand, and the blast furnace owners are compelled to buy largely in Belgium.

The Sugar Bounties Question.—The commotion raised by the London Conference on the sugar bounties question has subsided, the belief having become general that the proposals of the British Government will not be accepted. It is hard to see how the French Government can, in the face of the angry protests from growers and manufacturers, and the pressure which is being brought to bear upon them, do otherwise than reject these proposals.

The Glass Industry.—The glass industry in the North of France is in a fairly prosperous state, though the low prices now prevailing are beginning to provoke complaints. There are in this district seventeen coal furnaces, eight gas furnaces, and two open hearth furnaces, both of which latter are at Aniche.

Light Trains.—By a decree of the Minister of Public Works the Western Railway Company are authorised to run "light trains," that is, trains composed of not more than six carriages, to stop at any point between stations to take up and set down passengers without luggage.

AMSTERDAM, 24th January, 1888.

The Canal from Rotterdam to the North Sea.—In connection with this subject the Minister for Public Works at the Hague has informed the Dutch Legislature that he is working on the basis of an estimated total expenditure framed by his predecessor in office. The late Minister estimated that £1,250,000 more would be required to allow of the largest vessels passing through the canal to Rotterdam. £584,000 have already been expended since 1884, leaving £666,000 still to be spent on the work.

Telegraphic Communication with the Dutch West Indies.—The negotiations of the Government with the Pedro Seduengo American Telegraph and Cable Company of New York are now so far advanced that it is almost certain that both Dutch Guiana and Curaçao will be in possession of double telegraphic communication with Europe and Holland before the year is out. The above company has an exclusive Brazilian concession for land cables on the coasts of the empire from America. The company proposes to lay cables from Visca in Brazil to Paramaribo, the capital of Dutch Guiana or Surinam, and thence to Willemstad, Curaçao, provided Holland gives an annual subsidy for twenty years. The Dutch Government has agreed to do this. At Curaçao the above cables will connect with others, which the French Compagnie Télégraphique des Antilles is now laying to Hayti and Cuba.

NEW YORK, 14th January, 1888.

Railways.—The Central Traffic Association have reduced the rates of freight on iron and steel to places west of Pittsburg, much to the surprise of manufacturers, who were in expectation of an increase of 10 per cent. There was last year an increase of 1910 in the number of men employed by the New York Central Company, the total amounting to 20,170, who received £2,324,124 in wages and salaries. The company's coal tonnage increased by 762,912 tons, or over 25 per cent. The strike of the Reading Railroad employés has extended to the miners, and there are now nearly 50,000 idle men in the Schuylkill region. There is but little traffic on the Reading Road, and if the strike is not soon terminated many manufacturing concerns will have to shut down for lack of coal. The burning of coal dirt in the Wooten engines of the Reading Railroad is to be abandoned. It has been found to be one of the most expensive features of the road's equipment, and the present management of the road has decided to substitute standard boilers as soon as the Wooten boilers are worn out. Several have already been converted in the Reading shops. The first train that crossed the International Bridge at Sault Ste Marie consisted of 102 cars of flour loaded at Minneapolis for New York and Boston.

Bridges.—The contract for building the water spans of the Grand Avenue Bridge at St. Louis over the Mississippi, has been awarded to the King Iron Bridge and Manufacturing Company for £28,800. The approaches, which have already been erected, are 205ft. and 224ft. long, and the part which has just been contracted for consists of a central span of 400ft., and two anchor spans of 150ft. each, making the bridge 1129ft. long, including approaches. The entire cost of the bridge will be about £100,000.—Work has already begun on a bridge across the Hudson River, below West Point, which will form one of the most important links in the through system of roads from North to South. The approaches are being rapidly pushed forward.—The report of the Trustees of the New York and Brooklyn Bridge for the year ending December 1st, show the number of passengers carried in the cars to be 27,940,313, and the number of foot passengers 2,664,413, making a total of 30,604,726.

Glass Works.—A strike has taken place in the table ware departments of nineteen glass factories in different parts of the country, a large number of men being idle in consequence.

The Navy.—It is probable that Messrs. Herreshoffs will get the contract for a torpedo boat authorised by Congress. The design is for a boat of 130ft. length, having a beam of 15ft., and drawing 5½ft. of water aft and 2ft. forward. It is to be fitted with twin screws and triple expansion engines. The speed contracted for is 22 knots, with a bounty of £300 for each quarter knot from 22 to 23, and £400 for each quarter knot over 23. If the speed falls below 22 knots the penalty is £800, and the boat is to be rejected if the speed falls below 20 knots. The vote is for £20,000, and the contract price is £18,740. Messrs. Herreshoffs believe that the speed of the boat will be 24 knots.

PHILADELPHIA, 14th January, 1888.

Filtering Water for Cities.—There has been erected in Atlanta, Georgia, an apparatus designed to filter the water supply of the city. The plant consists of twelve cylindrical vessels, 13ft. diam. and 10ft. high. The water in passing into each filter is divided into two streams, the smaller of which is passed over alum. The streams again unite, and the alum causes the impurities in the water to become flaky, and the subsequent passing through coarse sand removes them. The quantity of alum taken up per gallon of water can be regulated by suitable valves governing the flow of water within certain limits; but the amount used is almost infinitesimal, and can have no bad effects on the user. A test of this plant showed that the daily capacity is 4,216,000 gallons, and the water became as clear and sparkling as spring water. The city of Paterson, New Jersey, is fitted with the same kind of plant, and it is also in use in many paper manufactories.

The Susquehanna Coal Company.—This company in their last report give the following particulars as to the cost of a ton of coal produced by them. The account is in cents, and is divided into two parts, the first covering all the expenses in the mine proper, and the second outside expenses:—

Inside Expenses:	Cents. per ton.	
Air and gangways	4·42	
Cars, slope, and drift	1·19	
Cross headings and chutes	4·13	
Exhaustion of land	7·04	
Mining coal	47·38	
Repairs, &c.	36·11	
Timber and props	7·75	
Total inside expenses		108·02
Outside Expenses:		
Insurance	0·38	
Legal expenses	·05	
Live stock	1·08	
Office	·13	
Preparing coal	11·71	
Repairs, general	5·37	
Royalties	2·01	
Stable expenses	3·99	
Stationery and printing	·18	
Stock coal expenses	·40	
Superintendence and clerks	1·65	
Taxes	1·18	
Total outside expenses		28·13
Total mining expenses		136·15

In the case of this particular company royalties are very low, as in some instances they are as high as 50 cents per ton, and the other expenses vary very much in different collieries from those given above. The cost of $1·36, or say 5s. 6d. per ton, is considered very satisfactory for the company.

NOTES ON FOUNDRY WORK.

By the Author of "Pattern Making."

(Continued from Vol. III., page 615.)

XI.

Turning Over.—This is, of course, the reverse of bedding in, and is the method adopted in the best work when not of too bulky dimensions. Still, like bedding in, the matter is usually one of the custom of the shop—men who are accustomed to work by one method preferring that to the other. Turning over is easier, and with good flasks is safer, than bedding in; and but for the large number of flasks required, would doubtless be adopted even more than it already is. There is less risk of unequal ramming in turning over than in bedding in, and less risk also of the casting becoming strained by the pressure of metal. In many cases bedding in is impracticable, as in long columns and similar castings, which are poured upright, and in small castings made in quantity and several moulded in a box. Each method of moulding is therefore especially adapted for certain classes of work. As I have given several illustrations of bedding in, I will now give three typical cases of turning over. A two parted flask, viz., cope and drag, are required in any case for turning over, and often there are three or more parts, and one or more middles, in addition to the cope and drag. Turning over then simply implies that the whole of the mould is contained within flasks, no portion being in the sand floor, and that the flasks are rolled over for the ramming of opposite faces. Hence we require no coke bed, for the air is all brought away at the joints of the flasks, at the bottom face of the drag, and at the top of the cope. Both the top and bottom faces of the mould are therefore rammed up on the pattern faces, and vented directly to those faces, and there is no tucking in, except under side angles and recesses. And, unlike bedded in moulds which can only be skin dried, turned over moulds can when desired be made in dry sand, and dried in the stove.

Take as a very simple illustration the trolly wheel (Fig. 54). First, the sand is roughly shovelled into flask A, trod down with the feet, and strickled off level with the top edge. On this sand the wheel is laid, and rapped down with the mallet until the central part of the rim, where the diameter is greatest, is about level with the box edge, as shown in the illustration. Then the sand is sleeked round that edge with the trowel, parting sand strewn over the joint, and the drag box B (Fig. 55) put on, and rammed up in a manner rather different from that which is adopted with a cope, inasmuch as no lifters are required. The flat bars being wide, the rammer has to be used diagonally as well as vertically between them. The surface, right to the face of the pattern, is then vented. The boxes being already cottared, are now turned over together, and laid with the flat bars downwards on a loosely rammed bed, levelled with the shovel only, parting sand intervening, and given two or three twists sideways to make a good bedding of the surfaces in contact. The vent wire is passed horizontally several times between the bottom face of the flask and the sand bed, to form a communication between the edges of the flask and the vents which run to the face of the pattern. The cope flask, or that into which the pattern was first bedded, is now lifted off and the sand knocked out, leaving the drag as in Fig. 56. A fresh layer of parting sand is strewn over the top joint face of the drag, and the cope put over again, then liftered, rammed up in the usual way, and vented; a runner pin being stuck on the central boss, and rammed beside the central core. The cope is then lifted, the pattern drawn, the moulds cleaned, cored, and blacked, and cottared or weighted. When cast, the boss is fed through the runner C (Fig. 57), which figure shows a section of the mould, all ready for casting.

As an illustration of a mould made in a three parted box, the sheave wheel (Figs. 58, 59, and 60) may be taken. Fig. 58 shows the first position of one half the wheel pattern, the box A being simply a bedding for the wheel, as in Fig. 54, while the drag B is rammed and vented over it, similarly to the drag in Fig. 55. When drag B is turned over on its bed (Fig. 59), A is taken away, and the sand knocked out, the top joint face of B is sleeked over, and strewn with parting sand. The middle part C is rodded, as shown, similarly to the middles which were shown in Fig. 17 (Vol. III., page 162). Clay water is swabbed over the middle placed on the drag, and partially rammed up, that is, about level with the joint face of the lower half of the pattern. To support the ring of sand which overhangs and forms the narrow groove of the pulley, nails of 3in. or 4in. in length are pushed down into the sand, as shown in Fig. 60, fulfilling therefore the same purpose as the larger rods in cores, and in cods of green sand. Then the top half of the pattern is put on, a weight laid above to keep it steady, and the remainder of the sand in the middle part rammed up to the top joint, that is, to the middle line of the flange D in Fig. 59. This, of course, may not happen to coincide with the top joint of the box; but when it does not thus coincide it is necessary to slope the face of the sand joint from the joint of the flask to the middle line of the pattern flange. This joint also is smoothed and strewn with parting sand, and lastly the cope E is put on, liftered, and rammed Then the boxes are separated for the cleaning of the mould, showing the impressions in the drag and cope precisely alike, and the middle as a ring of sand. Fig. 59 illustrates the mould in section, complete and ready for pouring; F indicating the pouring basin and runner.

The frame (Fig. 61) affords an example of turning over of a different style than those just noted. We have cope, drag, and middle; but the mode of making is not quite the same. There are masses of sand overhanging the metal spaces on each side of the central hole, which cannot be carried safely by any amount of rodding. A core would be suitable and safe, but would double the work in the pattern shop, and be therefore too costly, unless several similar castings were required. Hence a grid to carry the green sand middle is the alternative. There being no core, therefore it is necessary, in order that the pattern shall deliver itself, that one plate A (Fig. 61) shall be loosely dowelled to the sides B; and with the pattern thus made, we proceed with the moulding.

To commence then, the middle flask A (Fig. 62), rodded at the sides, is laid on the sand floor, roughly levelled with a shovel. On the bottom sand, the back of the pattern, or that which is afterwards to come in the top, is laid. Some facing sand is thrown within and around the pattern, and black sand above this again, until a considerable portion of the sides, say one-half or two-thirds, is rammed up. A central body of ashes is placed in, and then the grid. Since this has to rest upon the internal fillet of the middle part, it must at this stage, since the flasks are upside down, be screwed or wedged temporarily up to the fillet. A bar is therefore put through the eye of the grid, and by its means the latter is pulled up close to the fillet, as it appears in Fig. 62. The remaining sand is now rammed all over, both between and above the grid, and outside the pattern, and is finally strickled off level with those upper edges of the ribs upon which the loose plate is dowelled, that is, upon the joint B in Fig. 62. All the sand inside the pattern is vented to the central ashes, and to the hole in the centre. The outside is vented to the face B, just strickled.

The clamp, which held the grid securely during ramming up, is now removed, the loose framed plate (Fig. 61, A; Fig. 62, C) is placed on by means of its dowels. Fig. 63 shows a plan view of the mould at this stage. Some parting sand is strewn over the face, and the drag part (Fig. 62, D) put on, cottared, rammed up, and vented all over with say $\frac{3}{16}$in. vents, about 1in. apart. The flasks are ready now to be turned over, and so a thickness of parting sand is strewn over the top of the drag D, and this prevents sticking of the surfaces in opposition. The drag being turned over (Fig. 64, D), the sand around the now upper edges of the pattern is consolidated with the rammer and the hands before the cope E is put on. This is liftered and rammed. Then

Digitized by Google

the cope, the middle, and the pattern are separately lifted away from the drag, and all the parts cleaned and blacked ready for the final closing. Fig. 64 shows the mould complete with its pouring basin. Two main runners are provided, each of which, on reaching the level of the top of the mould, branches off into two or three broad thin ingates, which carry the metal in quickly without chilling, and without leaving large runners to be cut off afterwards.

In connection with this subject there is to be noted the use of "turnover boards," variously termed also "bottom boards," and "joint boards." Fig. 65 shows a plain bottom board. Upon its face the joint of a half pattern, or the face of a flat pattern, is placed. Over the pattern so laid the flask is set and rammed up, and being then turned over, the board is taken away, leaving a true joint face of sand to receive the other half of the pattern if a pipe or column, or the cope face if a flat pattern. Then, obviously this principle is capable of almost indefinite modification and extension, since the face of the board need not be a true surface all over, but only in those portions on which the joint edges of the flask abut. Other portions of the board may be cut to the irregular outlines of patterns, having edges whose corresponding sand partings are not in the plane of the board, but are either above or below. Moreover, the board may be either cut down or blocked up with sloping faces corresponding with the intended sloping sand joints of a more or less irregular character, and so save the moulder the trouble of cutting and sleeking his joints at every repetition of moulding—an important consideration in work often repeated. Fig. 66 affords an example of this modification of the turnover board. It is one used for ramming up the inside face of the pattern of a corner tank plate upon. It consists of a stout frame A, formed of four pieces halved together, and resting on the two cross bars B B. The pattern lies upon these, and dowels standing up therefrom, and fitting into corresponding holes in the tank plate, prevent it from shifting sideways. The inner longitudinal edges of the frame coincide with the chipping edges of the pattern section (Fig. 66). The inner transverse edges of the frame form the outlines of the sand points, being hollowed down (C C) to the curve of the plate, and chamfered back to allow of a free lift. The pattern D being laid on the frame, as shown in section, the drag is put on and rammed up. Being turned over, and the cope rammed and removed, the screws which hold the side flanges to the plate are of necessity withdrawn, owing to their radial position, which would prevent their withdrawal along with the plate. The plate is then lifted, the flanges following afterwards singly, leaving the mould free to receive the cores for the bolt holes.

Then again, in machine and plate moulding, further modifications occur, the flasks not coming together at all until the cope and drag are both rammed. There is very much involved in this subject of joint boards, but having explained their principle and purpose, I leave them for the present, but hope to refer to them again, in connection with the subject of plate and machine moulding. Other examples of turning over will also arise in connection with subjects of a special character.

(To be continued.)

Notices of Meetings.

THIS WEEK.

Society of Arts.—Friday, 27th January, 8 p.m. Indian section. Paper to be read on "The Public Health in India," by Mr. Justice Cunningham.

Royal Institution of Great Britain.—Saturday, 28th January, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

Physical Society.—Saturday, 28th January, 3 p.m. Papers to be read on "The Effect of Magnetisation on the Thermo-Electric Properties of Bismuth," by Mr. Herbert Tomlinson; On "The Influence of Magnetism and Temperature on the Electrical Resistance of Bismuth and its alloys with lead and tin," by Mr. E. van Aubel; and on "A Water Dropping Influence Machine," and on "The Price of the Factor of Safety in Lightning Rods," by Professor S. P. Thompson.

NEXT WEEK.

Society of Arts.—Monday, 30th January, 8 p.m. Cantor lecture on "Yeast, its Morphology and Culture," by Mr. A. Gordon Salamon, F.I.C., F.C.S.—Tuesday, 31st January, 8 p.m. Applied Art Section. Paper to be read on "The Monumental Use of Bronze," by Mr. J. Starkie Gardner, F.G.S.—Wednesday, 1st February, 8 p.m. Ordinary meeting. Paper to be read on "The Sweating System, or the Functions of the Middleman in Relation to Labour," by Mr. D. F. Schloss.

Institution of Civil Engineers.—Tuesday, 31st January, 8 p.m. Ordinary meeting. Discussion on Sir Bradford Leslie's (K.C.I.E., M.Inst.C.E.) paper on "The Erection of the 'Jubilee' Bridge carrying the East Indian Railway over the river Hooghly, at Hooghly." Paper to be read (time permitting) on "The Alexandra Dock, Hull," by A. C. Hurtzig, M.Inst.C.E.

Civil and Mechanical Engineers' Society.—Wednesday, 1st February. Paper to be read on "The Use of Ammonia as a Refrigerating Agent," by Mr. F. B. Lightfoot, M.Inst. C.E., M.Inst.M.E.

Institute of Patent Agents.—Wednesday, 1st February, 7 p.m. To resume the discussion on Mr. O. Imray's and Mr. E. Carpmael's papers. To read, and if time permit, to discuss a paper "On the International Convention as it affects the Granting of Patents of Invention," by Mr. A. M. Clark, Fel.Inst.P.A.

Institution of Mechanical Engineers.—Thursday, 2nd, and Friday, 3rd February, 7-30 p.m. Forty-first annual general meeting, annual report of Council, and election of office bearers. Discussion to be resumed on "Irrigating Machinery on the Pacific Coast," by Mr. John Richards. The following papers will be read and discussed as far as time permits: "On the Position and Prospects of Electricity as applied to Engineering," by Mr. William Geipel; and "Third Report of the Research Committee on Friction: Experiments on the Friction of a Collar Bearing."

Architectural Association.—Friday, 3rd February, 7-30 p.m. Ordinary meeting. Paper to be read by Mr. R. P. Spiers.

Geologists' Association.—Friday, 3rd February, 7-30 p.m. Annual meeting.

Royal Institution of Great Britain.—Friday, 3rd February, 9 p.m. Lecture on "Ancient Microscopes," by Mr. Frank Crisp.—Saturday, 4th February. Lecture on "Experimental Optics," by Lord Rayleigh.

PRICES CURRENT, 26th January.

Quotations at per ton, unless otherwise specified.

Tin: Straits	166	10	0	"	——		
" Australian	167	10	0	"	——		
" English Ingots	150	0	0	"	155	0	0

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper has been irregular all week, fluctuating from £79 to £74. There is very little actual business doing. It is said that the French Syndicate has nearly concluded arrangements for two or three years with several of the largest producers of raw copper, and this will regulate the price on a higher level. In the meantime trade in all branches of the copper industries remains exceedingly dull.

Tin remains firm, but lower prices are quoted for forward delivery.

Lead is lower, Spanish lead having fallen to £14. 7s. 6d.

Spelter is a little lower, owing to the re-sale of a large lot which had been bought speculatively. The market has again recovered as stocks are small, and all the producers well sold forward.

Erratum.—We regret that in the description of the British Empire Section of the Brussels Exhibition, given on page 66 of our last week's issue, an error occurred in referring to the official position of Mr. S. Lee Bapty. We think it well to correct this by stating that Mr. Bapty is Commissioner-General of the British Section, to which position he was appointed with the sanction of the Belgian Government.

We have received a copy of the first number of the *Locomotive Engineer*, a new American monthly journal devoted to the interests of drivers, firemen, and those employed in keeping locomotive engines in order. The journal is illustrated, and contains a large number of short, but very readable articles of practical interest, evidently written by men who have had experience in the round house, repairing shop, and on the road. The illustrations, which are well executed, refer mostly to tools required in the repairing shop. Science, either pure or applied, finds no room in this journal, but the articles are characterised by sound common sense. Amongst the matters treated we may specially mention articles on car heating, the setting of locomotive tyres, the practice of the round house, and a strong denouncement of the absurd claims now put forward by the Swinerton Locomotive Company for their flat driving wheels. The style of the articles is more peculiarly American than that of other American journals of a more scientific character, but nevertheless pleasant and fresh, and the printing is very good. We wish our contemporary every success.

Liverpool Engineering Society.—The opening meeting of the present session of this Society was held at the Royal Institution, Colquitt-street, on Wednesday; Mr. Charles H. Darbishire, Assoc.M.Inst.C.E., president, in the chair. Upon taking the chair the President delivered a short address to the meeting. Mr. A. W. Brightmore, M.Sc., then read a paper entitled "Some Recent Experiments on Iron and Steel and Riveted Joints." Mr. Brightmore reviewed the important series of experiments carried out at the instance of the Prussian Government by Wöhler and Bauschinger. He showed how these experiments pointed to the conclusion that, when the nature of the stresses in the members of any structure is subject to continual reversal, the maximum load consistent with the permanency of that structure is not more than one-third of what may with perfect safety be borne when the nature and amount of the stresses remain constant. Proceeding then to riveted joints, he dwelt upon the principles that guide their design, and concluded by demonstrating the advantages of machine over hand riveted joints.

HOME INDUSTRIES.

MANCHESTER, 26TH JANUARY, 1888.

THE ENGINEERING TRADE.—Now that business has settled down after the holidays, it is found that there is not much more work being actually placed with stationary engine builders. Generally speaking, they are only moderately employed, although there are one or two exceptions to this rule. Some good orders are in course of execution for India, and others are in the market for the same country; but on home account the orders which are talked about are neither many nor large. Millwrights are also a little better than they were, and in most cases could readily find occupation for more men. It is a hopeful sign that the trades unions have not so many members out of employment, which would indicate a general increase of work. Machine tool makers are as a rule fairly employed, but an increase of work is hardly to be looked for by them until the general industries of the country have improved. Locomotive builders are still short of orders, although there is a little more inquiry. Boiler makers continue well supplied with orders, and are almost without exception likely to be so for some time. The abolition of the old system of punching, and the more general application of scientific principles of construction in this branch, have led to a large increase in the amount of work put upon a boiler, with the result that the workmen engaged are mostly in full work. Machine makers are still busy, and it is gratifying to note that this is the case in almost all departments. Card room and ring spinning machinery is, perhaps, most in demand; but, speaking broadly, there is no lack of employment among machine builders. It is stated that Mr. Samuel Brooks is adding to his specialty of ring spinning frames the manufacture of carding engines and roving frames, having taken up the construction of a recently patented carding machine. Hydraulic engineers are badly off for orders, and have in addition to contend against a low range of prices. Within the past few years larger cylinders have been adopted in the type of baling press used in Manchester, a bore of 18in. being now usually adopted, and this has led to the substitution of steel cylinders for the iron ones formerly employed.

THE IRON TRADE.—The lower prices ruling in the Glasgow and Middlesbrough markets for pig iron are somewhat checking business here, but, except in the case of second hand parcels, there is no actual business being transacted at these lower rates. Makers, who are generally well sold at higher prices than those at present ruling, profess to believe in the probability of an advance, and are consequently very firm in their quotations. Local irons are being quoted at an average price of 40s. per ton, and hematite makers decline to sell at anything under the rates of a few weeks back, that is, about 55s. per ton delivered. Bar iron is also very firmly held, and has advanced in price, common bars being now quoted £5. 5s. per ton, although they can be bought at a lower rate than this. There is a fair call for steel boiler plates, which, along with all steel goods, maintain the advances recently noticed.

RIVER POLLUTION.—This subject, which, in view of the construction of the Manchester Ship Canal, is of great importance to this district, was considered at a conference, held in the Town Hall, on the 24th inst., and presided over by Lord Egerton of Tatton. Representatives from sixteen town councils, forty-eight local boards, and ten rural sanitary authorities were present, and resolutions were passed expressing the opinion that the time had arrived when the matter should be dealt with, and pledging the bodies represented to inform the chairman by the 25th of March next what practical steps were being taken by them towards this end. It was stated that the watershed of the Mersey embraced 606 square miles, and that of the Irwell 175,000 acres, the population affected being about 1,700,000. Various corporations have expended sums of money on this question, and it appears to be likely that a united effort will now be made to solve the difficulties of the question.

LONDON, 26TH JANUARY, 1888.

THE MONEY MARKET.—There is no great demand for money at present, even the rush for Bass debentures, which has been the only excitement of the past week, failing to harden rates at all. The stock markets are also exceedingly dull. The movements have been convulsive and without real interest or importance. At the close of last week the quietness of the stock markets was attributed to no particular cause, but with the beginning of this week the approach of the settlement, which began yesterday, was taken as a sufficient explanation of the idleness of the Exchange. British funds have been drooping a little, and foreign stocks are decidedly dull. There has been no great movement in home railways, with the exception of an occasional jump up or down in the southern Railways, as the phases of the struggle with Sir Edward Watkin have seemed favourable or otherwise to the prospects of a union between the southern lines. The one feature of the week has been the issue of the Bass debentures, which have been subscribed many times over at premiums ranging from 11 to 13, the issue price being 107.

COMPANIES.—Since our last report the following new companies have been registered: Alboline Oil and Varnish Company, Limited, with a capital of £25,000; Ducker Portable House Company, Limited, with a capital of £200,000; Colonial and Foreign Mining Syndicate, Limited, with a capital of £10,000; London and De Kaap Exploration Syndicate, Limited, South Africa, with a capital of £12,500; Roartey's Luck Mining and Developing Syndicate, Limited, South Africa, with a capital of £50,000; English Piano Manufacturing Company, Limited, with a capital of £15,000; Johns' Bottling and Stopper Company, Limited, with a capital of £100,000; Flameless Explosives Company, Limited, with a capital of £150,000; the Lane End Works, Limited, with a capital of £100,000, to acquire the Lane End and Oldfield Collieries and Brick Works, Staffordshire; Andalusia Iron, Coal, and Steel Works Company, Limited, with a capital of £1,200,000; the Great Grimsby Coal Supply Company, Limited, with a capital of £2,000; the Salterforth Water Company, Limited, with a capital of £1,000; Samson, Teale, & Co., Limited, with a capital of £10,000, to manufacture cycle and sewing machine fittings; Bass, Ratcliff, & Gretton, Limited, with a capital of £2,720,000; the Eastern Counties and British Farmers' Condensed Milk Company, Limited, with a capital of £100,000; Williams & Robinson, Limited, with a capital of £200,000; and Brain's Patent Tanning Company, Limited, with a capital of £25,000.

PRODUCE.—The rates both for cane and beetroot sugar have fallen owing to the operations of speculators, though no change has been reported in the prospects of supply which caused the recent rise. Should prices on the whole be maintained, there is a chance of the large sugar works at Silvertown being re-opened. The tendency of the coffee market is to decline.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 15th January, amounted to £1,059,289 on 15,830½ miles, as compared with £1,041,816 in the corresponding period of 1887, when the mileage was 15,706¾ miles. An increase is thus shown in the mileage of 123¾ miles, or 0·7 per cent., and in the receipts of 1·6 per cent.

THE NAVY.—The gunnery trials made at Portsmouth with the "Mersey" show that the arrangement of the circular shields adopted results in difficulties in working the guns. A modification will therefore probably be made. A new type of swift powerful sloop, to be built at Sheerness, has been designed by Mr. W. H. White, and will be the largest vessel of the class in the navy. She will have a displacement of 1580 tons and will be 220ft. long between perpendiculars, and 233ft. long over all, with a breadth of 35ft. She will be built of steel, and be fitted with torpedo tubes. She will be unarmoured, but the vital parts will be protected by a steel deck. The death is announced of Mr. W. B. Robinson, late chief naval constructor at Portsmouth Dockyard.

ELECTRIC LIGHTING.—Messrs. W. H. Smith & Son intend to instal the electric light in their extensive premises in the Strand. The wiring in connection with the same has been put into the hands of Messrs. Woodhouse & Rawson.

DRAINAGE.—As a result of the visit paid by the Margate Corporation to the sewage works at Friern Barnett, which we reported in Vol. III., page 664, the Drainage Committee of the Margate Town Council has recommended the board to employ Mr. Baldwin Latham to advise them generally as to the drainage of the town, and to submit a plan with estimate of cost.

COMMERCIAL EXAMINATIONS.—The Council of the Society of Arts have had for some little time under consideration the question of modifying or enlarging the system of commercial examinations, which have now for many years been carried on by the Society, in view of the recent demand for improved commercial education. At present, examinations are held in subjects covering pretty much the same ground as that defined in the new scheme of the Oxford and Cambridge local examinations; but certificates are awarded in single subjects, not on the general result of the examination. For some years the experiment of awarding general commercial certificates, instead of the separate certificates, was tried; but was found less satisfactory to the candidates generally. No decision has yet been come to respecting a change in the system; but it is probable that the system of separate certificates will be continued, and that it may be supplemented by the issue of general commercial certificates. The Society has already received a promise of £100 for a travelling scholarship from the Clothworkers' Company, and further assistance is requested of the same kind. The object of these travelling scholarships is, of course, to enable the holder to acquire that practical knowledge of foreign countries which can only be attained by actual residence abroad.

BRUSSELS EXHIBITION.—A meeting convened by Mr. S. Lee Bapty, Commissioner-General for the British Empire in connection with the Brussels International Exhibition, was held at the Mansion House on Tuesday, to promote the interests of the above Exhibition.

GLASGOW, 26TH JANUARY, 1888.

UDSTON COLLIERY EXPLOSION.—Mr. Ralph Moore, H.M. Inspector of Mines, has now issued his report on this explosion. He considers that it was a dust explosion, and recommends that shot firing in dry and dusty mines ought to be prohibited. He points out that the new Mines Bill permits shot firing in dusty mines under certain conditions, but he fears that these will be neglected and explosions must result.

SHIPPING.—Pig iron shipments show an excess of 30 per cent. over the corresponding figures of last year, and coal shipments an increase of 20 per cent. Freights outwards are still advancing. For the Mediterranean trade ships have been very scarce, and freights have in some cases been higher than they have been for some years.

TRADE SYNDICATES.—Negotiations have been in progress for bringing about an understanding between the American and the Scotch mineral oil companies, with the object of maintaining prices. A representative of the Standard Oil Company has been in Glasgow conducting the negotiations. Rumour has it that a number of the chief coal mining companies in the Glasgow district are about to consolidate themselves. The method of syndicated trade which has found favour on the Continent seems to be likely to take definite root in this country.

SHIPBUILDING.—A few more contracts have been placed within the past week. Messrs. A. & J. Inglis have booked an order for a yacht of 300 tons; and have laid the keels of the two 4000 ton steamers they are building for the British-India Steam Navigation.

THE FORTH BRIDGE.—A mischievous rumour, having its origin apparently in Stock Exchange operations, was current in the leading Stock Exchanges on Saturday, to the effect that mechanical difficulties had caused cessation of operations at the Forth Bridge. The rumour condescended to details, so far as to allege that one of the caissons had begun to slip. No one, of course, who had seen the structure would imagine that such a disaster could have occurred. Yet the rumour obtained so much credence that a fall of 30s. took place in North British Railway Stock. We are authorised to give the most unqualified contradiction to the statement. The work on the bridge has been progressing with a rapidity even greater than had been anticipated.

AGRICULTURAL EDUCATION.—Professor Wallace, of Edinburgh University, has issued a proposal for the development of agricultural education in Scotland. He urges the increasing of educational institutions rather than the establishment of experimental farms.

(From our own Correspondents.)

LIVERPOOL, 25TH JANUARY, 1888.

THE NEW ST. HELENS RAILWAY.—Arrangements have been made for the public cutting of the first sod of the St. Helens and Wigan Junction Railway, by the Right Hon. the Earl of Derby, K.G., on Saturday next, the 28th inst. During the proceedings Lord Derby will receive a unique present in the form of a solid silver model of a loaded waggon, measuring 10in. by 7in., every detail of construction being made to scale. The proposed line will be 18 miles long, commencing at Lowton, on the Wigan Junction Railway, where there is already a station, and terminating at Fazakerley, on the Southport Branch of the Cheshire Lines, a portion of the route being identical with that in the original scheme of George Stephenson for the Manchester and Liverpool Railway, abandoned on account of the opposition of a former Earl of Derby. After leaving Lowton, the line will pass through Haydock Park—where there will be a platform station for accommodation during racing and coursing meetings—Haydock, Parr, St. Helens, Denton's Green, Loughborough Road, Croxteth, and Fazakerley, at which places stations will be built. The chairman of the directors is Mr. R. Seton-Kerr, M.P.; the engineers are Sir Douglas Fox and Sir Charles Metcalfe; the contractors are Messrs. S. W. Pilling & Co., of Manchester, who have undertaken to construct the line in about two years. The capital of the company is £550,000.

SHEFFIELD, 25TH JANUARY, 1888.

THE HEAVY BRANCHES.—Iron and steel have been selling with tolerable briskness at about the same rates as last week; but local makers are not just now embarrassed by press of orders, and some manufacturers go so far as to say that the revival in trade is not by any means general. At the rolling mills, however, operations are more satisfactory, and the makers of railway material are on the whole busy, particularly on tyres, axles, and springs. Heavy machinery is in better demand, and one or two engineering firms—old established concerns like Messrs. Davy Brothers—are doing a steady trade. At nearly all the large works employment is fairly plentiful; and for edged tools and cutlery the market continues to yield good orders, considering the limited time travellers have been out since Christmas. The small-pox epidemic is now kept well in check by the authorities, and business men need have no fear in visiting the town.

LEEDS, 25TH JANUARY, 1888.

TEXTILES.—There is little fault to find with trade in the textile branches. Nearly all styles are selling well, but the largest purchases are of thick material for next winter's use. Woollens are still taking the fancy of buyers.

IRON AND STEEL.—In the heavy industries of Leeds there is a great deal of activity. The Bessemer output at Aireside promises well, and the market for manufactured iron is improving. Some extensive orders have recently been placed with Messrs. Kitson & Son, Messrs. Tannett, Walker, & Co., and one or two other large firms; and men are finding more employment than they did in the first quarter of last year. Nearly all the engineering firms are doing well; and for roofing, fencing, and other material

Digitized by Google

the demand is encouraging. Material for shipbuilding is more eagerly inquired for, and lately there have been a number of quotations passing for railway work abroad.

Coal.—In West Yorkshire the coal trade is brisk, but prices keep low, and there is little prospect of owners, even if they were inclined, being enabled to give the men an advance.

NORTH STAFFORDSHIRE, 25th January, 1888.

The Pottery Industry.—As has been repeatedly affirmed before here, prices of both china and earthenware have of late years been so low as to leave little or no margin of profit. With a view to remedy this condition of things, the Longton China Manufacturers' Association was recently formed, and on Monday last a large and representative meeting of earthenware manufacturers from all parts of the district was held at Stoke, to discuss the adoption of a similar policy to that pursued by the Longton Association. After a long discussion the following resolution was passed, with only one dissentient: "That this meeting, having heard the scheme of the Longton China Manufacturers' Association, believes that such scheme would form the basis of an agreement which would be advantageous to the whole body of earthenware manufacturers in this district." A working committee was appointed, including the principal firms and manufacturers in the Potteries Mining Institute. A meeting of the local institute was held on Monday last for the further consideration of the proposed special rules for North Staffordshire. The rules drafted by the joint committee of colliery proprietors and colliery managers, which had been appointed to consider this matter, were adopted after much discussion. It may be noted that the new provisions of the Coal Mines' Regulation Act, 1887, are acting very detrimentally to the interests of colliery proprietors in this district, the men in many cases absolutely refusing to comply with them except at a considerable advance in price. At one colliery, where an advance has been refused by the management, a strike is reported. It is calculated that the Act will add at least 3d. per ton to the cost of raising coal.

BIRMINGHAM, 25th January, 1888.

The Iron and Metal Trades.—The fall in the price of copper, consequent upon the syndicate becoming sellers, has had an adverse influence upon the iron market. The effect is felt, not in diminished price, but in a temporary lack of orders. At present there seems every probability that the syndicate will hold its own and maintain copper at something like £75; and if this proves to be the case, doubtless the lull in the iron trade will pass away. Stocks are becoming low, and dealers will in many cases be compelled to order on this account. The galvanisers are still busy, and one or two good roofing orders will keep them engaged for some time. Marked bars are £7, and unmarked ditto £5 to £6. Galvaniser's singles are £6. 5s. to £6. 10s., and doubles £6. 15s. to £7. In general hardwares there is fair activity, but scarcely so much as before Christmas. The Merchandise Marks Act, which recently came into operation, has helped somewhat to slacken business. Much uncertainty exists regarding the working of this Act in cases where a number of parts of one article are made by separate manufacturers, the so-called maker being merely a putter together of the pieces. It is much to be desired that test cases under the Act should be heard so as to clear up doubts. The agricultural colonies in the southern hemisphere appear to be in a fair state of prosperity judging from their demand for railway appliances; spades, shovels, hoes, and other cultivating tools are also in good request, and building requisites are in active demand. Trade in cheap brass founding is still checked by the price of copper; but in the higher and artistic branches, where the cost of raw material is of less moment, an increased activity is manifested, particularly as regards exports.

Cable Tram Cars.—The lines are now complete, and preliminary runs have been made with the new cars. Beyond a little temporary difficulty with the gripper, there has been no hitch; but the shopkeepers and others along the route are complaining of the ceaseless rumbling and grinding sound caused by the pulleys.

LEICESTER, 25th January, 1888.

Wool Spinning and Yarn Trades.—There has up to the present not been a very noticeable increase in trade, and although there is more doing than at the time of last report, business is still quiet. The tone of the trade has to a marked extent flattened, and the somewhat bright anticipations have not been fulfilled. Prices remain practically unaltered; country dealers and growers still ask late rates, and decline to deal on any other basis. But as spinnners are not operating staplers decline to deal, and at present the market generally is a waiting one. Should this continue it is probable that raw material will decline in price. The sales in London at the end of the month will largely influence the course of business. Spinners as a rule are fairly busy, and the year has opened somewhat hopefully; but orders drag considerably, and the uncertainty of prices increases this tendency. Yarn merchants are now busier, and are booking a few season orders, principally in cashmeres; but there is much room for improvement.

Hosiery Trade.—Business has not expanded to the extent which was anticipated, and is scarcely up to the average of the last year or two; yet orders are coming more freely to hand. The plain hosiery department is moderately employed, and spring samples are now out, and a few orders are already placed for them.

Boot and Shoe Trade.—There is a manifest improvement in this important industry; travellers are now well on their journeys, and orders have come more freely, and though the lines booked generally are not very heavy, they have sufficed to give fuller employment to the workpeople. Several large houses are now working full time. As a rule buyers, both wholesale and retail, are extremely cautious in purchasing. The tone of trade as a whole may be considered fairly cheerful, and there are anticipations of better trade in the next two months.

SOUTH WALES, 25th January, 1888.

The Coal Market.—There is an increased demand for all kinds of steam coal, best qualities selling as high as 9s. to 9s. 3d. The house coal collieries are also busy. Furnace coke is quoted at 14s. 9d. and foundry quality at 17s. per ton. The anthracite collieries in the Swansea Valley are directing their attention to the demand for anthracite "nuts," which has now existed for some considerable time. Two collieries have put up machinery for breaking up their coal, which has to be in pieces about the size of an egg, for facilitating its use in house stoves; but the accumulation of "smalls," which is inseparably connected with the process, is said to be a difficulty in the way of its general adoption, unless the demand very much increases.

The Tin Plate Market.—The sustained advance in the price of tin, and the unwillingness of buyers of tin plates to pay the necessarily enhanced values, have compelled manufacturers to make some attempts at concerted action amongst themselves. Although the formation of a syndicate by the whole trade is not an easy matter to effect, there is no doubt that the agitation stiffened prices whilst it lasted. Few things, however, could show so well of what heterogeneous elements the body of manufacturers is composed as the fact that no agreement seems possible even at so critical a period. As a consequence prices have again fallen, and some few makers appear to be entirely at the mercy of their buyers. 14s. to 14s. 3d. is the price now quoted for cokes. This trade, which, as regards the carrying, used not long ago to be almost a monopoly of Liverpool, the plates being sent there by rail, has now completely changed its character, and steamers like the "Montana," which recently left Swansea with 3000 tons, do the trade direct with the United States.

The Tin Syndicate.—This combination seems to have lost none of its original vigour. All the tin offering is being bought, a lot of 200 tons to arrive shortly having been taken at the highest figure ruling, viz., £166. 10s. per ton.

BARROW-IN-FURNESS, 25th January, 1888.

Iron and Steel.—The hematite iron trade remains very quiet, although makers are firm. Speculative sales have principally been made, and only a few legitimate sales between makers and consumers have taken place during the week. Prices are slightly higher, mixed numbers of Bessemer iron being sold at 45s. per ton net f.o.b., and forge and foundry samples at 44s. 3d. to 44s. 6d. Stocks in makers' hands are small. It is anticipated that the iron trade will revert to a more active position by reason of the facts that makers are busy and well sold forward, and that all the branches of trade which use Bessemer and ordinary hematite qualities of pig iron are busily employed and likely to require fuller deliveries during the season. It is believed that the present depressed tone is caused mainly by the influence of the Scotch pig iron market, and it is certainly a fact that the business done during the past few days has been mainly on speculative account, and not actual transactions between producers and consumers. The steel trade is quiet in rails, but prices are firm at from £4 to £4. 5s. per ton net f.o.b., according to section. Ship plates are in strong demand, and are firm at £7. 5s. per ton, while angles are in full inquiry at £6. 10s.; blooms are again in better request, and billets and slabs are in good demand, while wire and hoops are an improving trade. There is, in fact, every indication of a considerable industrial activity in the steel trade during the year, and this will doubtless have a similar effect on the iron trade.

MIDDLESBROUGH, 25th January, 1888.

Pig Iron.—The market remains steady at the price mentioned last week, viz., 32s. 3d. per ton for No. 3 G.M.B., although chance lots may be had at 32s. These are merchants' prices. Makers ask more—33s., and even 34s., per ton, but practically they have little to dispose of. The opinion is almost unanimous, however, that prices are bound to advance, and the tendency in that direction is felt already. Warrants are quoted at 32s. 3d. per ton cash. Hematite is at 44s., mixed numbers.

Shipments of Pig Iron.—The shipments of pig iron for this month so far are far ahead of those over the same period in January of last year, being 46,260 tons up to the 23rd instant, as compared with 26,914 tons, and the excess is not confined to any one quarter of consumption, but is spread over all. The preponderance of increase in export is to Scotland, and especially to other parts of England and Wales, the latter being as 13,440 tons to 2450 tons.

Manufactured Iron and Steel.—The finished iron trade still maintains its activity, and the increased prices are unaltered. There are orders placed which will take a considerable time to complete. The finished steel trade is scarcely so busy as it was, and prices are hardly maintained. The North-Eastern Steel Works have not yet finished repairs. The lock-out, if under the circumstances it can fairly be considered one, is practically settled by the agreement of both parties to abide by the decision of an independent arbitrator in all cases of dispute.

Salt.—This trade is very quiet just now, and the increasing competition has materially toned down prices. All varieties of salt are prepared, from that fitted for domestic use to that adapted for manure. The bulk is disposed of in chemical manufactures. There is not so much of it shipped at this season of the year.

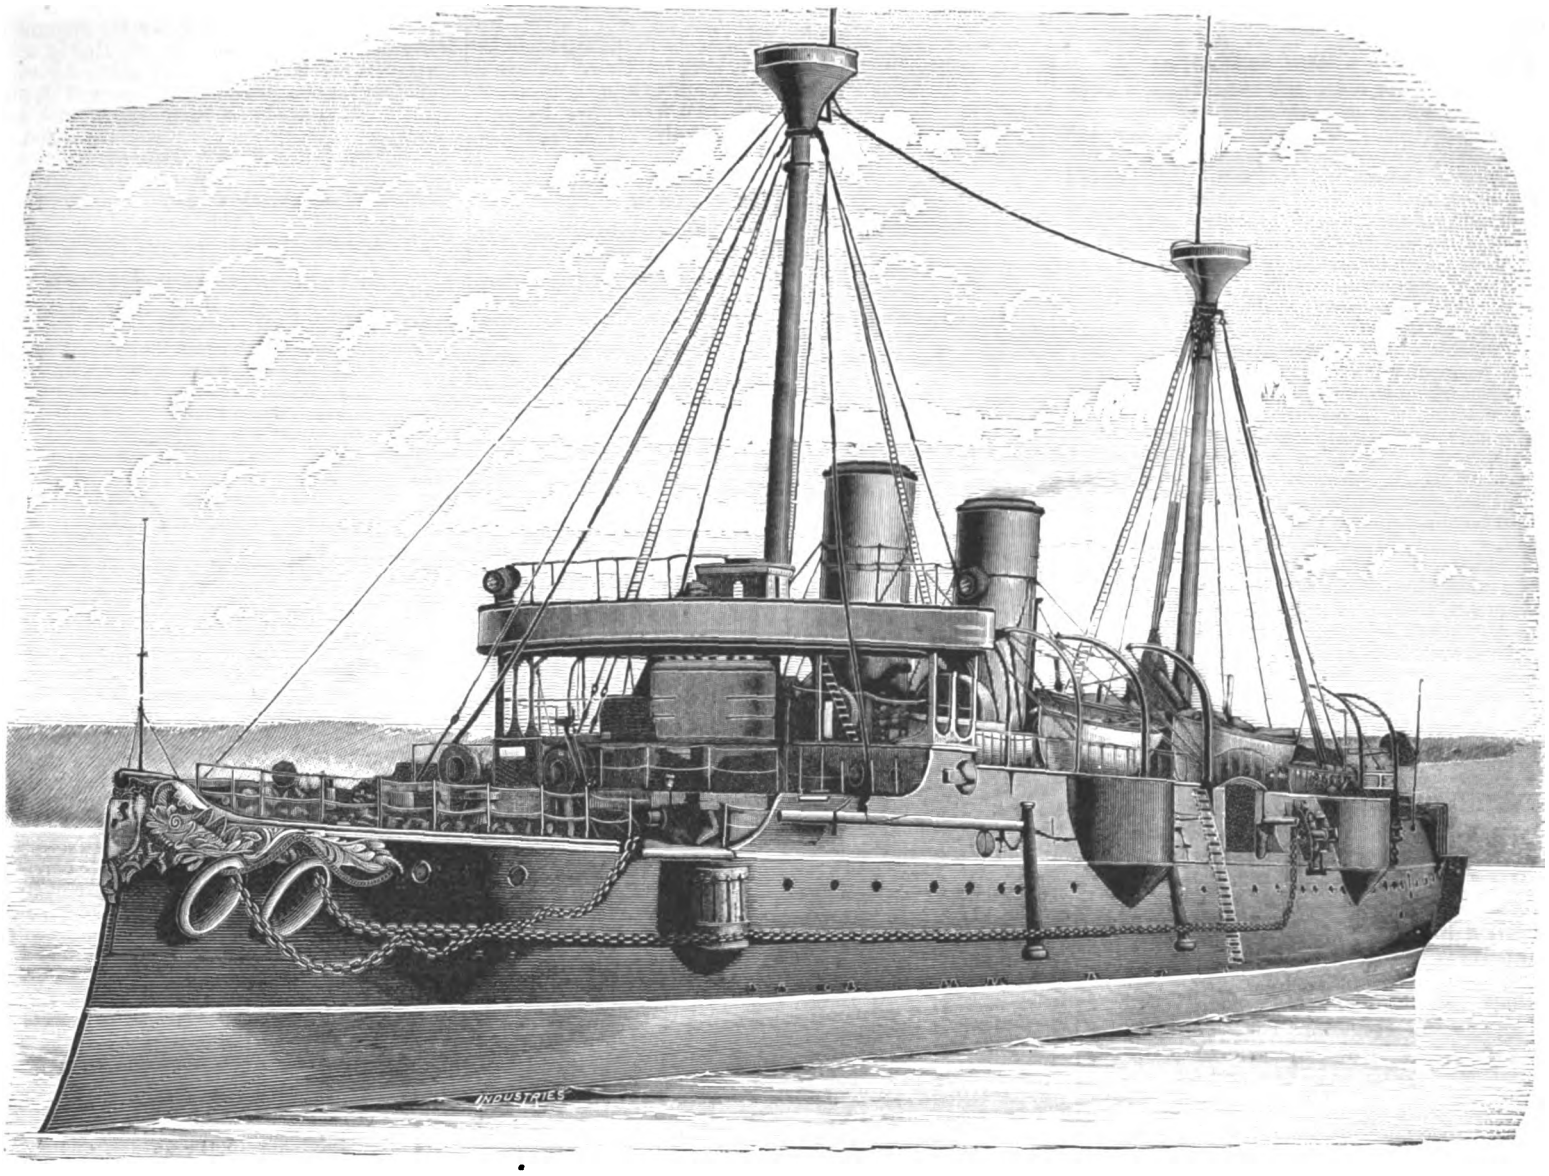
NEWCASTLE, 25th January, 1888.

Chemicals.—Though the prices of chemicals have not shown much inclination to advance lately, the demand for certain products which come largely into general use, such as bleaching powder, soda, soda crystals, caustic soda, and alkali, keeps fairly good. The output of these commodities is large, while stocks do not show much tendency to accumulate. The Newcastle Chemical Company contemplate largely extending the manufacture of caustic soda, and will commence at an early date to erect new works for this purpose. This extension will not cause any curtailment of production in the other branches of the chemical industry now carried on at the company's works. The Jarrow Chemical Company's establishment at Felling is very busy at present, especially in the manufacture of bleaching powder and alkali. The same description, however, does not apply to the company's works at South Shields, which for some time past have been rather slack. Messrs. Henderson's factory, Haworth Shore, is one of the busiest on the Tyne, the principal products being soda and bleaching powder. Messrs. Tennant's factory, Hebburn, is busy in the same branches, but some other establishments are not so favourably placed, and in one instance an early discontinuance of operations is anticipated.

Copper.—The Tharsis Copper Company are now doing a brisk business both at their Howdon factory, where the initial processes of the manufacture are carried on, and at their Hebburn establishment, where the metal undergoes the refining stages, and is finally turned out in its marketable form. There is a large demand on home account for the commodity commonly known as "blue billy," and considerable quantities are daily shipped to Middlesbrough and other centres of the iron and steel trades. The same commodity, after undergoing a special process of manufacture, finds a ready market in America, the quantity sent away since the beginning of the year being considerably over 3000 tons.

Lead.—In the different branches of the lead manufacture business is somewhat dull, but a hopeful feeling exists with reference to the future, and in the general revival of trade, which is now slowly but surely making itself felt, it is believed that this locally important industry must soon participate. The lead factory at St. Anthony's is already well employed, both in the sheet and red lead branches. At this establishment a special quality of lead is produced for exportation to China, and in this department considerable activity exists just now. The white lead department connected with this establishment has been for some time inoperative.

Colour Works.—Messrs. Shaw & Co.'s colour works, New Besswell, are exceedingly busy, the whole of the product being absorbed by American demand. The paint works at Stepney and Bill Quay are also very brisk, the demand from home and foreign sources being well maintained.



Shipping Notes.—Messrs. R. Stephenson & Co. have received from the Trinity House an order to build two large composite light ships, which will be laid down immediately at their Hebburn yard. The firm have orders for several steel steamers of a large class, two of which are now in early stages of construction. A moderate sized cruiser, which is understood to have been ordered by the Roumanian Government, was recently launched from the yard of Messrs. Armstrong, Mitchell, & Co., of Elswick. It is now receiving the engines and boilers at Messrs. Hawthorn and Leslie's works, St. Peter's.

BELFAST, 25th January, 1888.

General Trade.—All branches of industry are well employed at present, but there is not much unusual activity, and the number of hands employed continues to be under the average. Engineers and boiler makers are busier than they have been for some time, and several firms hold good orders for large sized land boilers. Felt makers are principally engaged on foreign orders. Aerated water manufacturers are doing well, and considerable quantities of the commodity have been exported during the winter months. Contractors and house builders find no lack of employment. The Durham-street Weaving Company (Belfast) opened their new concern on the 11th inst. They intend keeping 500 looms at work. Messrs. Stapley and Smith, of London, who already employ about 3000 hands in and around Londonderry and Strabane, have opened a new shirt and underclothing factory at the latter town. This firm has done much to bring this industry to its present position in the North of Ireland.

THE SPANISH CRUISER "REINA REGENTE."

THE PADDLE ENGINES OF THE S.S. "QUEEN VICTORIA."

We illustrate, on our two-page supplement this week, the engines of the paddle steamer "Queen Victoria," which, together with her sister ship the "Prince of Wales," was recently built by the Fairfield Shipbuilding and Engineering Company, Limited, Glasgow, to the order of the Isle of Man, Liverpool, and Manchester Steamship Company, Limited, for their line between Liverpool and the Isle of Man. The engines are of the compound direct acting type, indicating upwards of 7000 h.p., and have two cylinders placed one above the other, as seen in the illustration; the high pressure cylinder being nearly horizontal, whilst the low pressure is placed in a diagonal position beneath it, the space between the two forming a receiver for the steam exhausted from the high pressure cylinder. The two pistons, having each a stroke of 6ft. 6in., actuate two cranks placed at suitable angles. The low pressure cylinder alone is steam jacketed. Both the high and low pressure cylinders are fitted with ordinary slide valves worked by double eccentrics and link motion, and reversed by means of one of Messrs. Brown Brothers' steam and hydraulic reversing engines. All the working parts of the engines are of steel throughout, and the castings, with the exception of the cylinders and condenser, are also of steel. To further reduce the weight of the engines, the paddle shafts, crank pins, and reversing shaft are made hollow. The air pump is worked by a bell crank driven by a link from the connecting rod of the low pressure engine, and the bilge pumps, which stand on the sole plate, are worked by a lever attached to one end of the air pump rocking shaft. Separate donkey pumps on the Worthington principle are used for feeding the boilers; the water is circulated through the condenser by one of Messrs. Allen's centrifugal pumping engines. The engines are supplied with steam, at a working pressure of 110lb. per square inch, by four double ended steel boilers, one pair of boilers being forward and the other aft of the engines. The engine and boiler spaces are separated by coal bunkers. Each boiler has six of Fox's patent corrugated furnaces, making in all twenty-four furnaces. Air is supplied to the furnaces by Laing's patent system of forced draught. In this case four fans of 6ft. diam. are used—one on the top of each boiler—which draw the hot air rising from the stokehold, and force it through casings over the boiler uptakes down the ends of the boilers to the furnaces, thus thoroughly ventilating the stokehold, and at the same time supplying the furnaces with hot air. On the trial trip last June on the Clyde the "Queen Victoria" attained the average speed of 21 knots during six runs, or 24·2 miles per hour, with the engines making forty-five revolutions per minute. Her sister ship, the "Prince of Wales," however, shortly afterwards beat her, by going at the high speed of 24¼ knots per hour during a short run, and averaging 22·6 knots, or 26 miles per hour, during a six hours' run. We hope to publish further illustrations of these engines in a future issue.

THE SPANISH CRUISER "REINA REGENTE."

We give above an illustration of this interesting vessel, which has now passed out of the hands of her builders, Messrs. J. & G. Thomson, Clydebank, and is lying in the Clyde, off Greenock, ready for sea. A description of the ship was given in our columns at the time it was launched (see *Industries*, Vol. II., page 220); but as the vessel has since completed her speed trials, the following particulars may be of interest. The most striking feature is the high speed which has been attained in a heavily armed seagoing ship, with moderate dimensions and displacement. The speed of the ship under forced draught for a continuous run of four hours was 20·7 knots, while with natural draught it was found that a speed of 18½ to 19 knots could be easily maintained. The consumption trials indicate that it will be possible to steam at a speed of ten knots per hour for a distance of over 13,000 knots with the full coal supply of 1200 tons. These results have been attained by the adoption in this vessel of all the latest improvements which have been made in the construction of war ships, and especially in their propelling machinery. Among these may be mentioned the employment of twin screws, forced draught, triple expansion engines with a high boiler pressure, and the free use of wrought and cast steel both in the machinery and hull. In order to attain a maximum of protection with a minimum of weight and cost, the thick armoured sides, which have been adopted until lately in vessels of this class, have been replaced by an arched steel deck, extending for the whole length of the ship below the water line, and varying in thickness from 2in. to 4¾in. On the top of this deck arrangements are made for stowing a large supply of coal in numerous water tight compartments. The armament consists of four 21-ton breech loading guns, six 2½-ton guns, and a numerous armament of machine and quick-firing guns, four of which will be mounted in the military tops. There are also five torpedo tubes in different parts of the ship for discharging torpedoes on the Schwartzkopf system. While the offensive and defensive powers of the ship are thus of a most formidable nature, the ordinary equipment has been by no means sacrificed. There is a large complement of boats, including three propelled by steam, and capable of carrying quick-firing guns, and a considerable number of men; and powerful hoisting machinery is supplied for putting the heaviest of these boats into the water at short notice. The complement of men and officers is about 400 all told, and the entire main deck is devoted to their accommodation. Some interest attaches to the manœuvring trials of the "Reina Regente" as being the first large vessel that has been fitted with the balanced rudder, which has been patented by Messrs. Thomson. These trials were made last autumn in the Firth of Clyde, in the same manner as that in use by our own Admiralty, and the results showed that the vessel was capable of making a complete circle in three minutes when steaming ahead at a speed of 18 knots, the diameter of the circle being less than 3½ times the length of the ship.

Industries:

FRIDAY, 27TH JANUARY, 1888.

CHANGES IN THE CRUDE IRON INDUSTRY.

THE removal of the Dowlais Iron Works to Cardiff is one of the first visible effects of important changes which are taking place in the iron industry. By transporting their works from inland sites to the sea coast, manufacturers place themselves under new economical conditions. The very idea of such a change shocks our sense of what we have, from habit, come to regard as the fitness of things. The carrying of the idea into action so disturbs our judgment, by upsetting preconceived notions of what is natural and necessary, that we look on in bewilderment when some one, more far-seeing and enterprising than the rest, breaks away from old associations, and, like the Dowlais firm, casting prejudices aside, enters boldly on a new path. Hence it arises that the event which has stirred South Wales, and which has become the chief theme of conversation wherever a direct interest is felt in the manufacture of iron, is regarded with mingled feelings of astonishment, admiration, and misgiving. The reason alleged for this migration of works is the burdensome character of the railway charges. But these charges, which have not gone on constantly rising, would not be more and more grievously felt, nor would it be practically possible to evade them by such radical measures as those adopted by the Dowlais firm, and contemplated by others, if the economical and commercial conditions under which the works were originally founded had not materially changed. Here we touch upon the root of the matter. The progress of science, marvellously rapid in these latter days, has brought in new methods of iron manufacture. Old processes have undergone modification, fresh products have been arrived at, and the costs of production have been so diminished in certain directions that their distribution is no longer the same. The conditions and circumstances of trade have also greatly changed within the last two or three decades. Industry, which was formerly concentrated chiefly in these islands, has spread, till now we have to meet a formidable competition wherever we carry on an important trade. Easy and quick international communications, constantly diminishing freights, a more systematic conduct of commercial affairs, competition which gives grave importance to small matters, the spread of technical education; these and numerous other influences have combined to render the trade which we carry on to-day an essentially different thing from that of even a quarter of a century ago. In these altered circumstances manufacturing works situated on the sea coast may possess advantages over their inland rivals which may give them the preference, not only in the foreign but also in many of the home markets. Whether or not advantages shall accrue to the sea-side works is a question involving consideration of the particular conditions to which the industry there to be carried on is subject.

The location and grouping of existing blast furnaces, and consequently of finished iron and steel works, have been determined by conditions prevailing in the past, but which have mostly passed away. In times when two tons of coke was consumed in extracting one ton of pig iron from the ore, it was a matter of economical necessity to carry on smelting operations in the neighbourhood of the coal mines. It must, doubtless, always remain true, or so long, at least, as solid fuel is used in the blast furnace, that those localities in which abundant and readily accessible ores exist alongside rich coal seams, will produce iron most cheaply. But the difference between the past and present in this respect is that whereas formerly only such localities could be chosen as suitable seats of the iron smelting industry, now the choice is much less narrowly restricted. True, ore was often conveyed to these works from distant sources; but all ore so dealt with was of a rich character, and was used for a special purpose in conjunction with native ore. There is no instance of coal being conveyed long distances to the furnaces, none, at least, on a large and practical scale. It thus frequently happened that pig iron for export was subjected to the cost of a long land carriage, and though this charge was heavy, and our export trade in crude iron was very large, there was no remedy as long as the process of smelting required a large proportion of coal. For these reasons, many abundant deposits of ore, containing a fairly high percentage of iron, have been left neglected, even when on the sea coast and within easy reach of commodious ports, if they lie remote from seams of suitable coal. These are the principle characteristic features of a situation that has begun to pass away. Urged on by the necessity born of keen competition, manufacturers have sought to reduce the consumption of fuel, and, guided by a constantly widening knowledge, they have achieved no small success in that direction. By the middle of the decade beginning with 1860, the consumption of coke in the blast furnaces had been reduced, for ordinary qualities of ore, to 1·25 tons per ton of pig made. Since that date further progress has been made. The latest American practice, which seems to keep slightly ahead of our own, brings the quantity down to 0·8 ton. It is, moreover, to be remarked as a circumstance not without influence on the events we are considering, that greater knowledge and more efficient means of coking have enabled us to utilise for metallurgical purposes classes of coal formerly held to be worthless for coke manufacture. A little reflection on these facts is sufficient to reveal the wide significance of the changes which have taken place. To go no farther back than the period included between 1860 and 1870 for a comparison, it is quite another thing to transport from the collieries to the blast furnaces 80 tons of coke, instead of 125 tons, for every 100 tons of pig iron made. There is no reason to believe that the lowest limit has yet been reached, so that we may, without straining probabilities, contemplate a future, even in the present century, in which 75 tons of coke will be the standard for ordinary practice. Under these new conditions it is easy to understand that the proprietors of the Dowlais works will find it more advantageous to bring their fuel rather than their iron down to Cardiff. On the coast they will be in the best position for the export of their produce, either coastwise or to foreign parts, and for the reception of the foreign ore which they find it necessary, or desirable, to use. Here we have the key to the position. When we have recovered from the surprise which the announcement of this new departure has occasioned, we shall recognise the wisdom of the step, and find encouragement in the knowledge that our manufacturers are alive to the needs of the times, and sufficiently enterprising to give effect to the judgment they form concerning the requirements of the situation.

Digitized by Google

The question has a wider bearing than that we have hitherto assigned to it. The migration of our large inland works to the sea coast is certainly a matter of high importance to the prosperity of our iron industry; but the movement will not stop there, and its further development is likely to shape our destiny in the industrial world in a yet higher degree. The conditions now prevailing invite the transference of British energy and British capital to foreign shores. This movement is, indeed, in progress now; but it has not yet involved, except in an incidental way, the blast furnace industry. And yet the fairest prospects are in this direction. The opportunity will assuredly not be neglected by the foreigner. What we may expect is to be seen in the line of action adopted by the Italians. These enterprising people, though placed at a serious disadvantage by nature in depriving them of coal, have determined to establish a great iron industry. Already surprising progress has been made. What this progress has been is partly indicated by the fact that our export of coal and coke to Italian ports increased from 2,354,103 tons in 1884 to 3,186,854 tons in 1887. Hitherto the Italians have directed their attention chiefly to the development of the finished iron and steel branch of the industry, importing most of their crude iron from England—55,749 tons in 1885, 69,175 tons in 1886, and 122,994 tons in 1887. But they have at the same time done something towards the utilisation of their own abundant and rich deposits of ore. There are blast furnaces in operation working on native ores with imported English made coke, and the results having been found satisfactory, projects are being formed and preparations made to gradually extend the system. Much of the Italian ore is rich in iron and of remarkable purity. The Elba ores are well known. But there are others of good quality in abundance, and within easy reach of the sea ports. Now, if we assume the cost of manufacture on the spot to be the same as in this country, it will be manifestly more advantageous to import 75, or even 80, tons of coke than 100 tons of pig iron from England. But labour is cheaper in Italy than here, so that the advantage would be made greater on this account. These facts are being pressed upon the attention of the Italian Government, who may be expected to protect this young crude iron industry by imposing, before the present century is out, a heavy duty on foreign pig iron. We cite this example as the most striking out of many that might be adduced. It is sufficient to indicate the probable course of events. Others will suggest themselves to our readers. The department of the Meurthe-et-Moselle in France is a case in point. That locality, which is the principal pig iron making centre in France, has no coal. The whole of the coke consumed in the blast furnaces is imported partly from Belgium and partly from the department of the Nord. Under the conditions of iron manufacture prevailing a quarter of a century ago, the Meurthe-et-Moselle, rich as it is in excellent ores, could hardly have competed successfully with its neighbours, which have received their smaller endowment of ore along with the coal necessary to reduce it. The future has probably in store for us many examples of this sort, and we are made to think of these by the reports which reach us from across the Atlantic of 5510 tons of pig being made with a consumption of 4425 tons of coke, and by the announcement from South Wales relating to the migration of the great Dowlais Iron Works.

THE PANAMA CANAL.

The position of the French Government in the Panama Canal question becomes increasingly difficult as the chances of making the canal on the original plans, and within the stipulated period, are gradually vanishing. When, under M. de Freycinet's administration, M. Rousseau, the chief engineer of roads and bridges in France, was dispatched as one of a commission to investigate the progress made in Panama, French investors naturally expected to receive straightforward advice as to the wisdom or otherwise of putting money into the undertaking; but M. Rousseau's report was not by any means conclusive. It contained, on the one hand, an abundant glorification of the great French canal maker as to his moral character and general ability; and, on the other, an assertion that the undertaking would prove impracticable unless the original plans were considerably modified. When French investors, belonging generally to the middle and poorer classes, have sunk sixteen millions sterling in an undertaking, no Minister would dare to advise the abandonment of the scheme, and so the Panama Canal went on swallowing successive loans, not, indeed, with the sanction, but at any rate under the tolerance, of the Government. At the present moment more money is again required, and this time M. de Lesseps actually proposes that the French Government should assist in procuring it for him by bringing in a bill to authorise a lottery. The reason he gives for raising money by such means is his anxiety to secure to Frenchmen the glory and substantial reward of having supplied the whole of the capital required for the canal; but his request has not been received in this patriotic spirit by the Government, both M. Tirard and M. Rouvier flatly refusing to lend State aid to such a lottery. The bill for sanctioning the lottery will, therefore, have to be brought in by a private member, and considering the great personal influence of M. de Lesseps, and the fact that amongst the constituents of almost every member there are many who would suffer certain and immediate loss by the abandonment of the canal, it seems likely that the bill will pass.

It is interesting to note that simultaneously with this new attempt to raise money, M. de Lesseps has virtually abandoned his original scheme for a low level inter-oceanic canal without locks. It is announced by M. Max de Nansouty, in the *Genie Civil*, that the change of plans was adopted in consequence of the representations made by M. Eiffel, who came to the rescue with an offer to construct the necessary locks, in order to avoid the gigantic earth works which would otherwise be required in cutting through the central range of hills. Only by this means will it be possible to get the magic streak of water between the two oceans within the stipulated time, and M. de Lesseps knows only too well that on the moral effect of this feat the financial success of the whole undertaking depends. The total length of the canal is about forty-six miles, and according to M. Eiffel's plan there will be the following locks: The first of 26ft. lift at the fourteenth mile from Colon, the second of the same lift at the twenty-third mile, and two of 36ft. lift at the twenty-seventh and twenty-ninth miles respectively. By means of these four locks a height of 124ft. above the sea level will be reached in the eastern portion of the canal. In the western or Pacific portion there are to be three locks of 36ft. each, and one of 26ft.; but it is possible that to reduce the amount of cutting on the watershed one more lock may be found necessary, making the difference of level between the Atlantic and the highest point in the canal 160ft. All the locks but this last one will be supplied by gravitation from rivers; but for the highest lock steam pumps will be necessary, the total power being estimated at 3600 h.p. The locks will have a minimum width of 59ft. at the entrance, and will be 590ft. long. M. de Nansouty calculates that with a speed of six miles an hour in the straight reaches of the canal and 2½ miles in the bends, a vessel will pass from one sea to the other in 17½ hours, and that ten vessels will be able to pass through daily. Under these conditions the total annual capacity of the canal would slightly exceed nine million tons of traffic. Since this figure is in excess of the traffic originally estimated by the Panama Canal Congress (7,500,000 tons), it is difficult to see why the Eiffel scheme should be considered by M. de Lesseps as only provisional; but in the article already quoted we are told that the canal with locks is only intended to establish communication as quickly as possible, and that the original scheme of a low level canal without locks will be carried out as soon as the provisional canal is in working order.

GLASS BOTTLE MAKING BY MACHINERY.

In the closing weeks of last year we were thrown into a happy frame of mind, as a fitting preparation to the festive season of Christmas, by an announcement loudly trumpeted forth by the daily press and more feebly echoed by some of the weekly technical journals, to the effect that a British inventor had triumphed over difficulties which none of his predecessors had been able to cope with, and had thereby rendered British manufacturers, if not exactly able to "lick all creation," at least competent to hold their own against their Continental rivals in the glass bottle making industry. The discovery of this bright prospect in one of our industries was made by a party of upwards of thirty newspaper representatives "of all sorts," who, at the invitation of Messrs. Sykes, Macvay, and Co., travelled from London to Castleford, Yorkshire, on the 16th of last month. In the week following, newspaper articles dealing with the glass bottle trade abounded, and this exertion has been kept up, for in *The Times* of Wednesday last there appeared a description of this invention. The public were led to believe—that is, that portion of the public which is in the habit of taking its opinions ready made from the newspapers—that a complete revolution in the bottle making industry was about to take place, that the cost of labour was to be reduced from 3s. 6d. to 3d. a gross, that in consequence of this enormous reduction we should be relieved from the oppressive competition of the foreigner, that the life of a glass blower was to be prolonged to the allotted span of three score and ten years, and that, in a word, an age of prosperity for the British bottle maker was about to dawn above everything we could ask for or imagine. When blessings pour down in this April shower sort of way, we are apt to suspect that things are not what they seem. It may be that there has been no exageration in this case; but we must confess to a feeling of apprehension that the prospect is too good to be true. This apprehension becomes, unhappily, greater as we look more closely into the facts which have been set forth for our delectation by the newspaper reporters aforesaid. Some of them will scarcely bear a near inspection; others change their aspect under examination.

We have no desire to depreciate Mr. Ashley's invention, which may possess all the merits claimed for it. Doubtless it is regarded as a practical and efficient machine by those who have taken it in hand, and it is not unlikely that it has a great future before it. But seeing that it has scarcely passed beyond the stage of a working model, we cannot but view as premature all practical conclusions arrived at concerning it. A large number of patents has been taken out in past years, both in this country and abroad, for machines to do the same work. For some reason or other these have not come into use. We are told by some of the newspaper representatives that the Castleford machine differs from these only in the mechanism for moulding the neck. Now, on this point, a high authority on glass bottle making assures us that a moulded neck can never equal in strength one made in the usual way. The glass which is put by hand round the neck to form a strengthening band acquires, as it is drawn out, a kind of grain or fibrous structure, which gives it a greatly increased resisting power in the direction of its length, and thus forms a hoop of sufficient strength to withstand the pressure of the cork.

But passing this by as a matter of detail, there remain some objections to the views enumerated in the articles resulting from the trip to Castleford. It is calmly assumed, as if the matter were beyond the possibility of doubt, that this machine will practically give a monopoly of the trade to those who obtain a license to use it. But when, as in this case, an inventor has been preceded, accompanied, and followed in the same field by so many competitors, and the records of the Patent Office are crowded with specifications, it is hard to see what claims can be made that shall be wide enough to keep every workable machine in the hands of the owners of Mr. Ashley's patents. Another unjustifiable assumption is that the manufacture of bottles by this machine involves no more than its erection at existing works. The trades unions have already set their faces rigidly against the introduction of such machinery, and those who know the glass trade will be aware that only by the erection of new works and the employment of a fresh set of men, outside the control of the unions, can mechanical manufacture be successfully established in this country. Any change of this character must, therefore, be slowly effected, and under conditions which will largely checkmate the advantages afforded by the new system.

But it is when dealing with the commercial side of the question that we find ourselves most at variance with the statements so confidently put forward. Take, for example, the evidence adduced to show the importance of the trade which, it is alleged, is to be recovered by adopting this machine. "We are importing," so runs the statement, "16,000 gross of glass bottles a day from the Continent." In another place we are told that the Continent, in this case, means Germany and Belgium. This then is the trade which we are to win back by means of the Ashley machine. Let us see how these figures will bear close inspection. Assuming that the 16,000 gross is an average for the 310 working days only, the imports for the year must amount to 4,960,000 gross, or more than 700,000,000 bottles. It is to be borne in mind that Messrs. Sykes, Macvay, & Co. are described as makers of wine, beer, spirits, and aerated water bottles, and pickle jars, and that all the remarks made appear to have reference to those classes of bottles. In these circumstances we may presume the 16,000 gross to consist chiefly of such ware. Now the works of Messrs. Sykes, Macvay, & Co. are said to be amongst the largest and best equipped in the kingdom; they give employment to 300 hands, and their daily output of bottles is 420 gross. We are further informed that these hands are unable, by reason of the exhausting character of the

Digitized by Google

labour, to work more than five days a week. Basing a simple calculation upon these data, we learn that to manufacture 714 million bottles said to be annually imported from the Continent, forty-five such works as those of the Castleford firm, or their equivalent, employing 13,500 hands, must be kept going full time. This is a startling revelation, and it is moreover of a character to suggest doubts. Proceeding a step further, these doubts are resolved into absolute disbelief when we compare the results of our calculation with the records of the import trade in glass contained in Board of Trade returns. We there find that the "Unenumerated Manufactures of Glass," under which description bottles are included, imported in the year 1887 amounted to 746,153cwt. These goods consist chiefly of bottles; but the total, it is to be observed, falls short of three-quarters of a million cwt. The weight of ordinary wine, beer, and spirit bottles is about 230lb. per gross, that of half bottles and aerated water bottles about 150lb., and pickle jars average about the same as the aerated water bottles. We should not be far wrong if we assumed 200lb. as the average weight of all the imported bottles of these classes. But to keep on the safe side, we will take 180lb. Multiplying by this average, we find the weight of the 714 millions of bottles to be about eight million cwt., a quantity nearly eleven times greater than that given in the Board of Trade returns. Turning now to the official statistics of the importing countries, we learn that the quantity of glass bottles shipped from Germany to Great Britain in 1887 amounted, in round numbers, to 123,000cwt. It is probable that this quantity was swollen by a considerable proportion of the same class of goods sent from Hamburg and Bremen; but the total consignments did not exceed 690,000cwt., and of course only a part of this quantity came to England. The Belgian Customs returns show that the exports of bottles to England were last year under 300,000cwt. It is clear then from these facts that if the statement in question is in any sense true, it must have reference to such small ware as medicine and scent bottles, of which, by the way, it may be remarked that we are ourselves large manufacturers. But granting the possibility of making up the numbers in this way, the disparity in the figures cannot be explained away in this manner. The weight of common medicine bottles—those that are most largely used—is about 45lb. per gross. Now, if the 16,000 gross said to be imported daily were made up wholly of these bottles—which, of course, is not the case—the total quantity would amount in the year to two million cwt., a quantity greater by some 337,000cwt. than that of all the glass goods of every sort imported in 1887.

Leaving it to the authors of these large statements to explain away on other grounds the difficulty which to us is insuperable, we readily admit that the import trade in bottles is of sufficient importance to be worthy of an effort for its recovery. But assuming that the Castleford machine is about to be generally adopted in this country, will the result be, as predicted, to at once crush out this import trade? We think not. What is to prevent the foreigner from adopting mechanical manufacture in his turn? If there is but little hope of creating a monopoly at home, there is still less of controlling the industry abroad. In nearly all Continental countries where inventions are protected by patents, a manufacturer can compel the inventor to grant a license to use the machine on reasonable royalty. But in a case like the present, in which the task of avoiding the patentee's claim is easy, a different course would probably be followed. Anyhow, the foreign manufacturer would keep pace with his British rival, and the conditions of the trade would, in their international features, remain unchanged. It is admitted that the glass bottle trade has gone to Germany and Belgium, because labour is cheaper in those countries than in our own. Probably, then, there is but one means of recovering this trade, viz., by equalising the rates of wages. When the British trades unions have seen fit to level down to the Continental point, or when the foreign trades combinations have succeeded in levelling up to the British rates, which, of course, would be preferable, then—and not till then—these large imports will disappear from the Board of Trade returns.

THE PARIS ELECTRICAL LABORATORY.

While our own Electrical Standards Committee, instituted by the Society of Telegraph Engineers and Electricians, is apparantly unable to get together the funds necessary for the establishment of a laboratory where electrical instruments could be officially tested in a manner similar to that adopted at Kew for thermometers and watches, French electricians have progressed much better in this respect, the reason evidently being their command of a considerable fund which was left over from the Paris Electrical Exhibition of 1881. As the electrical laboratory in Paris will shortly be opened, a brief sketch of its history may be interesting to our readers. The Paris Exhibition was not only scientifically and technically, but also financially, a great success, and at the close of it the general commissioner, M. G. Berger, was able to hand over to the Minister of Posts and Telegraphs the sum of £12,000, to be used eventually as a fund for the establishment of some kind of electrical laboratory. For a time the matter remained in abeyance, there being no public body of sufficiently strong position to initiate a work of such importance. But after the establishment of the International Society of Electricians in 1883, with M. G. Berger as its first president, this Society instituted a committee to report on the ways and means for establishing the laboratory, whilst the president took the necessary steps at the Ministry of Posts and Telegraphs in order to have the fund transferred to the control of the Society. In due course, the secretary of the committee, M. E. Sartiaux, published a report containing particulars of various other electrical laboratories, and based upon this report the Society definitely resolved to carry out the project for which the fund was originally intended. In this task they were well supported by private manufacturers, the Brothers Menier, for instance, giving them, rent free, land and buildings at No. 20, Rue Rouelle, in the Quartier de Grenelle; whilst a steam engine, a gas engine, and some electric machines and apparatus were lent free of charge by the respective makers. The buildings required some slight alterations, which were carried out under the superintendence of M. Dutreuil, the architect to the International Society of Electricians, but otherwise very little money was needed to complete the internal fittings of the laboratory. In consequence of this economy the greater portion of the fund is still intact, and the interest will be used to provide the working expenses. The Society, now under the presidency of M. Mascart, has appointed M. de Nerville as general director of the laboratory. This gentleman is a telegraph engineer, and is well known in France for the work he did there years ago in connection with MM. Mascart and Benoist in making a determination of the legal ohm. The programme of the laboratory is a fairly wide one. It is proposed that facility should be given to private individuals and manufacturers of electrical machinery for making researches which they could not carry on at their own laboratories or works. It is also proposed to standardise electrical measuring instruments, and to supply with each instrument which has been tested a certificate showing its limits of error; also to test electrical machinery generally, and to institute researches which the International Society of Electricians might deem of sufficient general utility.

Letters to the Editor.

A NEW DEPARTURE IN WELDING.

To the Editor of "Industries."

Sir,—With reference to Mr. Fletcher's letter, published in several of your contemporaries, it may interest him and your readers to know that for years past we have, in the manufacture of Fox's patent corrugated boiler furnaces, been welding Siemens mild steel plates from $\frac{1}{4}$in. to $\frac{3}{4}$in. in thickness with ordinary gas and air, using a form of blow pipe jet. The aggregate of our welding during the past year would be represented by some 20,000 lineal feet, the tubes being from 2ft. to 5ft. in diameter, and made to work at pressures up to 200lb. per square inch. The amount of oxide formed is dependent upon the relative amounts of gas and air employed, an oxidising flame producing more and a reducing flame less. The surfaces of our tubes are perfectly clean and free from scale, which shows an absence of oxide.

Yours, &c.,
W. L. Wildy, Engineer.

Leeds Forge, Leeds, 24th January, 1888.

TRANSMISSION OF POWER.

To the Editor of "Industries."

Sir,—I must demur to your statement on page 40 that the experiments between Kriegstetten and Solothurn, in Switzerland, "have shown that about 75 per cent. of the power at the generating station is actually available at the motor station, the distance over which the transmission takes place being close upon five miles." The power at the generating station is said to have been about 40 h.p., and the dynamo was big enough to absorb the whole of this. Only 50 per cent. of the power available was therefore delivered. What was measured was the power expended on the armature of the generator, and that given out by the motor when both were working together, and these were in the ratio 100:75. We ought to know the power expended on the generator when the motor was replaced by an equivalent resistance, and when it was free from the reaction of the back e.m.f. The ratio $\frac{\text{power delivered}}{\text{power available}}$ is a very different thing to $\frac{\text{power delivered}}{\text{power expended}}$. The power available is usually measured when the motor is out of circuit, the power expended when the motor is in circuit. This does not appear to have been done in Solothurn, and is a blot on those otherwise admirable experiments.

Yours, &c.,
W. H. Preece.

G.P.O., London, 18th January, 1888.

BELGIAN FOUNDRY PRACTICE.

To the Editor of "Industries."

Sir,—In Mr. Dixon's presidential address, printed in your issue of the 20th inst., there is a statement to the effect that in a certain Belgian workshop moulds are made without patterns, the drawings being sent direct into the foundry. If any of your readers can give detailed information on this very exceptional workshop practice, it would be both novel and interesting to a large number of technical men.

Yours, &c.,
The Author of "Pattern Making."

25th January, 1888.

THE BOARD OF TRADE INSPECTORS AND GREEN'S ECONOMISERS.

To the Editor of "Industries."

Sir,—In the report of a preliminary inquiry (No. 242) under the Boiler Explosions Act, 1882, upon an explosion of a Green's economiser at Junction Mill, Chadderton, Lancashire, I find the following expression of opinion given by Mr. William H. Woodthorpe, who it appears made the inquiry in question, viz., "the working of these *so-called* economisers (the italics are mine) should be attended to with great care, as only by so doing will disastrous explosions be avoided; and it would be well if the nature of the material from which these apparatus are constructed were fully understood by those interested." He then goes on to say in reference to these "*so-called economisers*" that "in this mill five boilers are employed, but four only are used at one time. Under these circumstances I am inclined to think there is little need for an economiser being fitted, as by easily working all the boilers at once the owners would effect a substantial saving." These statements are supplemented by the following "observations" among others by his chief, Mr. Thomas W. Traill: "Cast iron, it is hoped, is getting to be regarded as an unsuitable material of which to make such apparatus. I have before expressed my opinion on this point, and I regard such structures as described in this report to be a constant source of danger."

I presume that before Messrs. Traill and Woodthorpe decided to publish such statements they must have had at least some facts and foundation to rest them upon. As the document is public property, and they are public servants, it seems to me there is no impropriety in my inviting these gentlemen to give the reasons for the faith that is in them on this subject; and I shall be glad to know: First, why does Mr. Woodthorpe describe Green's economiser as a "so-called economiser?" That expression—if it means anything—would indicate that it is only so in name and not in fact. If he has sufficient evidence to support that statement it should be at once made public, as steam users have for the last thirty years had implicit reliance upon this apparatus producing an economy of from 15 to 25 per cent. of the total fuel burnt under their boilers, according to the circumstances of each case. Many thousands of such apparatus are in use, and an enormous sum has been expended upon them. Similar apparatus are every day being applied, all of which outlay might be saved if Mr. Woodthorpe be correct. He gives in the case of the Junction Mill, Chadderton, a suggestion: Four boilers only, he states, are usually worked, and an economiser, and to discontinue using the economiser and to use in its stead a fifth boiler, or, to use his own words, "By easily working all the boilers at once the owners would effect a substantial saving." I would here just ask what would be the further saving effected by putting down and using a sixth, or say a seventh boiler, and so on? That is to say, where does the saving produced by adding boiler room stop? Will Mr. Woodthorpe supply the formula for calculating this point. In another part of Mr. Woodthorpe's report, speaking of the heat to which the pipes were exposed, he says: "I would estimate the temperature of the pipe to have been about 560°F." By this, I presume, we may fairly assume that the escaping gases were at a temperature of at least 560°. If so, then experience shows that a saving of from 20 to 25 per cent. would be produced by fixing a Green's economiser; but if putting in another boiler instead will "effect a substantial saving" even upon that result, engineers who are not connected with the Board of Trade have, it would appear, still much to learn, and also to unlearn.

It would be most interesting to know on what basis Mr. Woodthorpe's opinions on this most important matter rest, and if he can substantiate his statements, he will confer a great boon not only upon steam users, but also upon the great body of engineers who have for so many years been recommending and erecting these "so-called economisers."

Further, "these structures"—by which I suppose is meant Green's economisers—are in the opinion of Mr. Thomas W. Traill, "a constant source of danger," and can only be prevented from "disastrous explosion" by being "attended to with great care." Might I ask Mr. Woodthorpe whether it would not be well to give us a list of the explosions which have already occurred to "these structures," and the proportion they hold to the number of economisers at work? Is it not, sir, a fact within your own knowledge, that economisers receive little or no attention, are seldom or never inspected, and in fact, are not the whole of the conditions laid down by Mr. Woodthorpe totally neglected? And yet, with the exception of a few cases, little trouble is found to be given by "these structures," either from the nature of the "material" used, or the manner in which they are designed. So little risk is experienced or thought of in relation to them that it is only within the last few years that insurance companies have canvassed for their insurance, and I very much question whether even the largest insurance company has one hundred insured, amongst the 23,000 boilers under its charge.

It appears to me, so far as evidence is obtainable by ordinary persons, that Messrs. Traill and Woodthorpe have grossly misrepresented the risk accruing from "such structures," and that they have needlessly raised a feeling of serious alarm in the minds of a very large number of steam users. If Messrs. Traill and Woodthorpe can confirm their statements much good may result; but if, on the other hand, they have no solid grounds for their action, much mischief has been done by raising feelings of doubt and dread with regard to one of the greatest improvements in steam engineering of the present generation.

Yours, &c.,
Manchester, 21st January, 1888. Economiser.

TRIPLE EXPANSION ENGINES FOR TEXTILE FACTORIES.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Replying to the inquiry of your correspondent "H." in your issue of the 13th inst., as to "whether any makers have as yet applied the system of triple expansion to stationary engines for textile factories," I beg to state that, so far as my knowledge goes, the first occasion on which such an application was made was in January, 1868 (just twenty years ago), at Messrs. Day, Nephew, & Son, Calder Wharfe Mill, Dewsbury. Triple expansion engines were then made in conformity with the patents of my father, Mr. J. S. Crosland, of Manchester, and to his designs and drawings. They consisted of two low pressure cylinders of 28in. diam., and two intermediate cylinders 18½in. diam., all having a stroke of 5ft., and two high pressure cylinders 14½in. diam., each having a stroke of 2ft. 6in. The engines ran forty revolutions per minute. From the annexed diagrams, taken 2nd September, 1870, by the Boiler Insurance and Steam Power Company, Manchester, it will be seen that with a pressure of 135lb. per square inch in the boiler at the time of indicating, an average pressure of 71lb. was maintained in the high pressure cylinder, 26·1lb. in the intermediate, and 6·4lb. in the low pressure cylinder of No. 1 engine, and of 71·4lb., 26·4lb., and 5·97lb. in the corresponding cylinders of No. 2 engine, developing altogether 410 i.h.p., and that for a weekly consumption of 24⅓ tons of coal, or at the rate of 1·85lb. of fuel per i.h.p. per hour.

Diagrams taken from the Triple Expansion Engines belonging to Messrs. Day, Nephew, & Sons, Calder Wharfe Mill, Dewsbury. September 2nd, 1870.

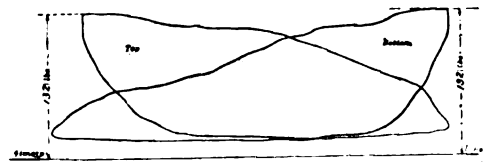

DIAGRAM OF HIGH PRESSURE CYLINDERS—Diam. 14½in., Stroke 2ft. 6in.

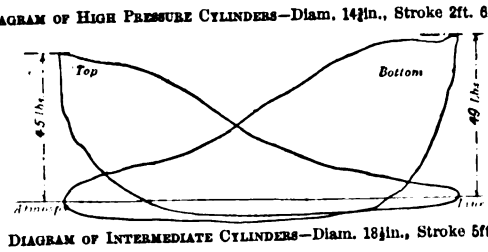

DIAGRAM OF INTERMEDIATE CYLINDERS—Diam. 18½in., Stroke 5ft.

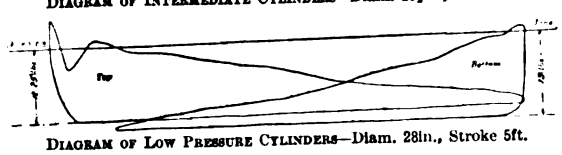

DIAGRAM OF LOW PRESSURE CYLINDERS—Diam. 28in., Stroke 5ft.

Steam for these engines was supplied from two boilers, modifications of the elephant or French type. The size of the fire grate of each boiler was 4ft. by 4ft. 6in., giving a total fire grate area of 36 sq. ft. The evaporative power of these boilers did not exceed 6lb. of water per lb. of fuel consumed, and the result attained of 1·85lb. of fuel only per i.h.p. per hour, shows clearly the extremely economical results obtained by these engines. An examination of the diagrams given herewith will show the very small weight of steam used per i.h.p. Had boilers of the marine type or of the multitubular class been employed, and an evaporation of from 9lb. to 10lb. of water obtained, the result would have equalled anything that has so far been done either on land or afloat.

Diagrams taken from the Triple Expansion Engine belonging to Mr. Thomas Ashworth, Cleator Mill, Carnforth. July 11th, 1872.

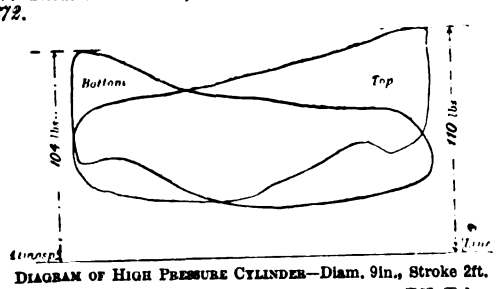

DIAGRAM OF HIGH PRESSURE CYLINDER—Diam. 9in., Stroke 2ft.

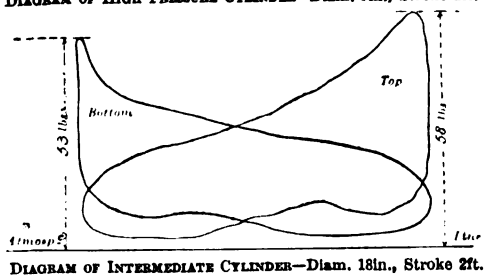

DIAGRAM OF INTERMEDIATE CYLINDER—Diam. 18in., Stroke 2ft.

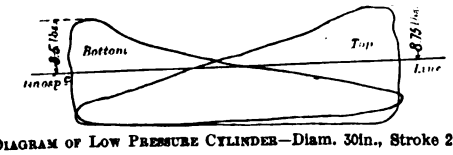

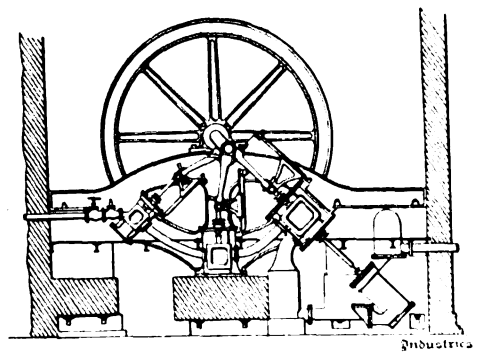

DIAGRAM OF LOW PRESSURE CYLINDER—Diam. 30in., Stroke 2ft.

In the year 1870 the Fairbairn Engineering Company, Limited, Manchester, constructed and set to work a triple expansion engine from the patented designs of my father, at the Cleator Mill, Carnforth, belonging to Mr. Thomas Ainsworth. The high pressure cylinder in this instance was 9in. diam., intermediate 18in., and the low pressure cylinder 30in., each cylinder having a stroke of 2ft., and the engine ran sixty-six revolutions per minute. All the three cylinders, and also the connecting pipes between the cylinders of this engine, were steam jacketed, and supplied with steam direct from the boiler. From the diagrams taken 11th July, 1872, also by the Boiler Insurance and Steam Power Company, it will be seen that the average pressure in the high pressure cylinder was 50lb., that in the intermediate cylinder 25·25lb., and that in the low pressure cylinder 11lb. The feed water was used entirely cold. The total power developed by the three cylinders was 138 i.h.p., and the coal consumption 2·2lb. per i.h.p. per hour. Steam for this engine was supplied by two of Sir William Fairbairn's patent boilers, at a pressure of 150lb. Each of these boilers consisted of three shells 3ft. 9in. diam. and 22ft. in length; the upper shell being placed above two lower ones, and used for a steam and water reserve, the lower shells having one internal flue each, 2ft. 9in. diam. The evaporative power of this boiler would not be great, and probably did not exceed 6lb. or 6½lb. of water per lb. of fuel The same remarks as to the excessive cost of producing steam and the further economy which might have been produced by more economical boilers for this engine apply as in the case of Messrs. Day, Nephew, & Son. So thoroughly satisfactory in every respect was the working of this engine, that Mr. Ainsworth ordered and had fixed alongside a duplicate engine, in the year 1872.

CROSLAND'S TRIPLE EXPANSION ENGINE. 1868.

Having regard to the great interest now taken in high steam pressures and triple expansion engines—especially by marine engineers—and to the claims made for their introduction into general practice, it may be interesting here to remark that my father had previously laid his designs for the triple expansive working of steam engines, and using high pressures of 150lb. and upwards, before Sir William Fairbairn; and so thoroughly did he agree and concur with my father's views, that he made arrangements with him for the sole right of making his triple expansion engines under his patents. Sir William was making arrangements for starting this work when his failing health and subsequent death put an end to the further prosecution of the scheme. The principle of triple expansion, the use of pressures from 150lb. and upwards, and my father's general designs, had his full approval, and he would but for his death have been instrumental in bringing them forward and giving them the prominence they deserved, in which case your correspondent "H" would probably not have required to make his inquiry, as the system would have been as well known and appreciated for stationary purposes as it now is for marine engines. Marine engineers have, I believe, and as I have shown, simply followed, and have not originated or led to this change in engineering practice, as "H" appears to think; and in proof of this I send you the above illustration showing one design of my father's engines. A description of a similar engine was given by your contemporary *Engineering*, page 392, 3rd June, 1870, and on page 394 of the same issue there is a good illustration. A full description of the Fairbairn boiler can be found in the same journal, commencing at page 298 in the issue for 3rd May, 1872.

Yours, &c.,

J. F. L. CROSLAND.

Manchester, 17th January, 1888.

TO THE EDITOR OF "INDUSTRIES."

SIR,—In reply to your correspondent "H.," whose letter appeared in your issue of the 13th inst., we beg to state that we are now manufacturing triple expansion engines for electric lighting purposes. If you will kindly publish this reply to "H." we shall deem it a favour.

Yours, &c.,

MARSHALL & Co.

Keighley, Yorkshire, 20th January, 1888.

Reviews.

THE BRITISH COLONIES AND THEIR RESOURCES. By James Bonwick, F.R.G.S. London: SAMPSON LOW, MARSTON, SEARLE, & RIVINGTON. 1886.

This book was written in view of the recent Colonial and Indian Exhibition, not only for the purpose of directing attention to the contents of that Exhibition, but also for creating a wider interest to the heritage of the people of these British Isles in distant places. It is a very useful contribution to what has recently been called commercial geography, and it contains notices of British Colonies in Asia, British Colonies in Africa, British Colonies in America, and British Colonies in Australasia, and special attention has been devoted to those least known to the general public. As the author remarks, traders of every sort, manufacturers and merchants, are interested in a knowledge of the resources and requirements of our own possessions. Politicians can no longer afford to pass by Colonial topics, as the prosperity of the British Islands is now indissolubly associated with the welfare of our dependencies, upon the sound principle that trade follows the flag. A closer connection of all parts of the British Empire with its three hundred millions of people is much to be desired, since the world's true progress will be thereby so extended and hastened. Such a connection can only be brought about by the collection and distribution of correct information regarding the various parts, and books of the class we are noticing will be extremely useful for these purposes.

TRANSACTIONS OF THE NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS. Vol. III. Edited by the Secretary. Newcastle-upon-Tyne, 1887.

We are much pleased to find that the third volume of the Transactions of the North-East Coast Institution of Engineers and Shipbuilders maintains the high standard of the two previous volumes. The papers are excellent in quality, and the discussions add much to their interest and value, while the volume is well got up both as regards printing and illustrations. We are sorry, however, to observe that the Institution has spent more money upon it than was warranted by the ordinary revenue. We trust, however, that arrangements will be made for increasing that revenue, and that the members will not allow the quality of their Transactions to deteriorate. The volume under consideration begins with a list of the publications received in exchange for the Transactions, and a summary of their contents which will be exceedingly useful to the members. One of the greatest wants of the present day is a convenient system of reference to the work done in the different departments of pure and applied science. An immense amount of energy is spent on work which is practically buried, and if the results of that work were more generally available much time and money would be saved. The inaugural address of the President, Mr. Doxford, was noticed in almost all the scientific journals at the time of its delivery, and afforded material for a considerable amount of discussion, which we need not now renew. The paper by Messrs. Nichol and Gravell on "The Use and Transport of Liquid Fuel" will be useful not only to engineers but also to merchants who require to study the commercial aspects of the questions involved, while that by Mr. Mudd on the "Plan and Construction of Marine Engine Works" is a very good study of the conditions which are of importance in all such works, rather than those which are rendered expedient in particular works owing to local circumstances. The elaborate paper by Mr. Foster on "The Principle of Work" in relation to the strength of structures, and the fallacy of "The Accepted Theory" of the strength of hollow shafting drew out a long and interesting discussion. We have not space even to summarise these, but we may say that although some points of Mr. Foster's paper were shown open to dispute, still it contains a large amount of experimental duty of much interest and considerable importance, while the discussion brought out some interesting points. Mr. Gannaway's "Notes on the Launching of Vessels" contain the results of much observation, and introduced a good discussion. That on "Technical Education for Engineers and Shipbuilders," by Mr. Ivan Mavor, has a melancholy interest on account of the premature death of its author by the explosion on board the petroleum steamer "Petriana." We have reproduced this paper in these columns, and we will only say that it gave evidence that its talented author was as well qualified to discuss educational matters as to superintend the practical operations of shipbuilding. The most important paper, however, in the volume is that by Mr. Blechynden on "The Reaction and Efficiency of the Screw Propeller." In it the question of the screw's reaction and efficiency is examined almost wholly from an experimental point of view, and an endeavour is made to bring forward in the light of practical experiment such facts bearing on the subjects as, in the opinion of the author, are insufficiently appreciated. The paper is neither intended as a treatise on screw propulsion nor as an explanation of the method of designing a screw, but is addressed to engineers who are acquainted with the general facts of the case, and gives facts bearing on some of the phenomena involved, with the intention of leading to a clearer appreciation of the working of a screw in water, and we commend it to the study of marine engineers. The last paper is by Mr. J. P. Hall, on "Compound *v.* Triple Expansion Engines, from a Ship Owner's Point of View," and contains a large amount of information of great value not only to the ship owner, but also to the marine engineer. An appendix to the volume gives the programme of the visit of the Institution of Naval Architects to Newcastle, and a short account of the Mining, Engineering, and Industrial Exhibition, which has recently closed. Taken as a whole, we have seldom read a volume of Transactions with so much pleasure as the one which we have now briefly noticed.

SIR WILLIAM THOMSON'S ELECTRICAL MEASURING INSTRUMENTS.

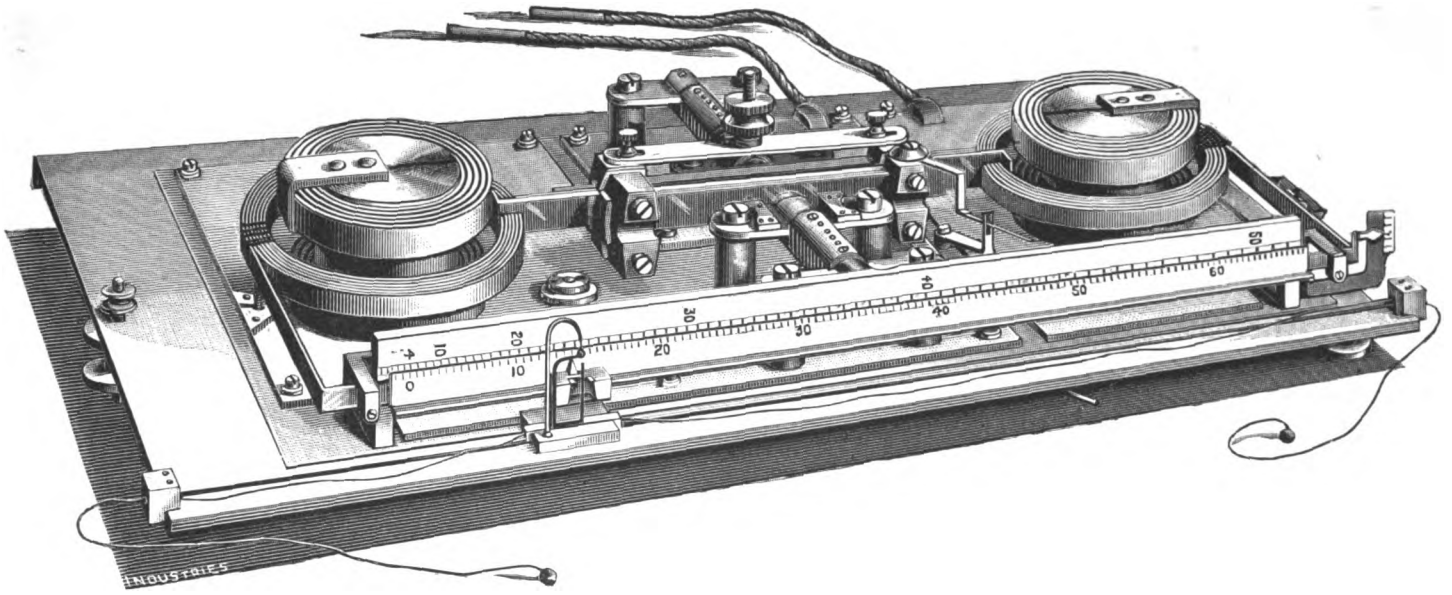

FIG. 1.

SIR WM. THOMSON'S NEW STANDARD ELECTRICAL MEASURING INSTRUMENTS.

BY J. A. FLEMING.

FOR the last six years, Sir William Thomson has been engaged in developing and perfecting a complete series of instruments for the measurement of electric currents. Beginning with the now well known graded galvanometers, he has finally accomplished the task of providing a connected group of instruments, which may be broadly classified into three divisions: (1) Standard direct reading electric current balances; (2) magnetostatic galvanometers or lamp counters; (3) marine and engine room voltmeters. The standard direct reading electric current balances are standard instruments, in which every source of possible error arising from the use of permanent magnets or soft iron is eliminated, and the operation of these instruments consists entirely in weighing, by means of standard weights, the attraction or repulsion between movable and fixed coils of wire conveying electric currents. These standard current balances may be said to be modifications of the electro-dynamometer, which was first described by Weber in his "Electro-dynamische Maasbestimmungen" (Leipsic, 1846). The foundation of the electro-dynamometer was, however, laid long previously. On 25th September, 1820, Andrè Marie Ampère announced to the Royal Academy of Sciences, in France, that he had discovered the existence of forces of attraction and repulsion between conductors of non-magnetic material traversed by electric currents. The experiments of Ampère and the elaborate researches of Weber (W. Weber, "Electro-dynamische Maasbestimmungen, Thl. I., s. 10, 1846, Auszug in Pogg Annal, Bd. LXXIII., s. 193), established the fact that if there be a fixed and a movable conductor in the neighbourhood of each other, traversed by the same electric current, there will in general be a mechanical stress brought into existence, which will tend to displace the movable conductor, and bring it into a position relatively to the fixed conductor in which the mechanical stress between them is zero. The mutual force or stress between these mutually influencing portions of the same circuit is, in any given position, proportional to the square of the strength of the current traversing the two portions of the circuit. In Sir William Thomson's standard instrument this stress is measured by comparing it with or balancing it against the weight of certain standard masses; in other words, the electro-dynamic stress is compared with the gravitation stress on a given mass.

The great difficulty which has hitherto presented itself to all who have attempted to design instruments on the electro-dynamometer principle for any but very small currents has been that of getting the current into and out of the movable conductor. The device on which most experimentalists have fallen back is that adopted by Ampère himself, viz., to use mercury cups as a means of constructing a flexible and conducting joint. The use of mercury is open to many objections. The surface gradually becomes oxidised, the cups must be filled and emptied each time, the instrument has to be transported, and the joint with impure mercury is by no means exceedingly flexible. The great achievement in these instruments has been, first, the invention of a joint or electric coupling which is excessively flexible, and at the same time capable of being constructed so as to carry with safety any current desired. This has been accomplished by the introduction of a device which may be called a metallic ligament. The general principle of its construction, and the mode of rendering a circuit freely movable, yet accessible to a large current, may be described as follows: Let A A (Fig. 2) be a pair of semi-cylindrical fixed trunnions, which are carried on some form of supporting frame, and held with the flat sides downwards. Let B B be two similar trunnions, which project out from the sides of two strips, connecting together a pair of rings C C. The pair of rings and the connecting strips constitute the circuit which is to be rendered movable. A current entering by the trunnion + B flows round the two halves of the circuit, as shown by the arrows, and emerges at the trunnion – B. In Figs. 2 and 3 the current is shown dividing round the two rings; but we should explain here that this has been done by an oversight. The circuit should be shown so that the current goes round both rings in series, in figure of 8 fashion. This is the case in all but the kilo- and hekto-ampère balances, in which the current divides round the ring. To the upper surface of the upper trunnion are soldered a very large number of exceedingly fine copper wires (No. 60 B.W.G.), which are laid close together. These wires are also soldered to the under surface of the lower trunnion. The movable circuit C C thus hangs from the

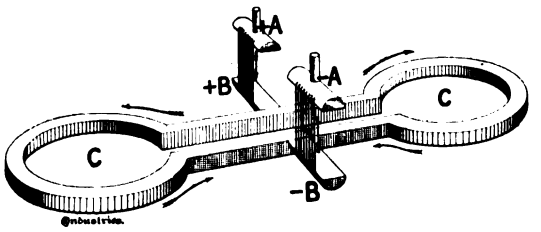

FIG. 2.

upper trunnion by two ligaments, which appear like thin strips, but which are really composed of an immense number of very fine wires. In Fig. 2 these ligaments are intentionally drawn much longer in proportion to the rest of the figure than they really are in the instrument, the object being to render the mode of suspension clear. This method of suspension enables the conductor C C to vibrate freely like a balance by a motion which is partly a bending of the flexible ligaments, and partly a sort of rolling and unrolling of the lower trunnion on the ligament attached to it. By this ingenious method not only can a heavy copper conducting circuit of the shape shown be suspended as freely as the beam of a good balance, but at the same time a very large current density can be permitted in the flexible ligament, since its great radiating surface, and the freedom with which heat is taken out of it by conduction into the mass of the trunnions, allows a proportionately very large current to be transmitted. If, then, the trunnions A and B are the electrodes, the method above described affords the means of passing a very large current into the circuit C C, which yet at the same time retains within certain narrow limits great freedom of movement. Let such a suspended conductor be arranged so as to have a circular conducting circuit of annular form, briefly called an ampère ring, placed above and below each of the movable rings of the balanced arm. Let the connections be made as shown diagrammatically in Fig. 3, in which it will be seen that the current entering by the + electrode flows in series through all four fixed ampère rings F, and in parallel through the two movable ampère rings M. An examination of the direction of current flow in each ring will then show that, in consequence of Ampère's law (parallel currents in same direction attract, in opposite direction repel), forces of attraction and repulsion will

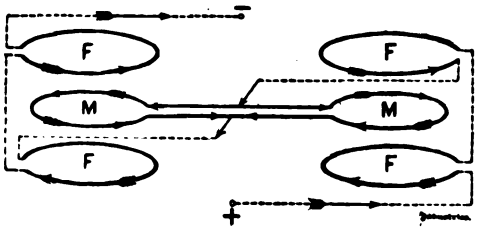

FIG. 3.

be brought into play between each fixed ring and the movable rings, which tend to lift one ring M and depress the other, and tilt over the balance arm to which they are attached. The ampèrian forces thus exert a couple on the movable part. To bring back the movable part to its initial position, which we may suppose to be half way between each fixed ring, an equal and opposite mechanical couple must be applied. We shall in what follows call the movable part of the conducting circuit the balance coils, and the other portion of the circuit the fixed coils. The operation of weighing an electric current consists,

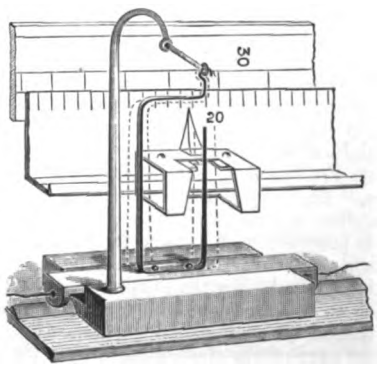

FIG. 4.

therefore, in bringing first of all the balance coils into a definite sighted position between the fixed coils, then passing the current, and bringing back the balance coils into the sighted position against the displacing electro-dynamic forces by applying to the balanced part a couple produced by a standard weight. The restoring couple is applied as follows: Attached to the balanced part or movable portion is a stiff metal bar, turned up at the bottom edge so as to form a sort of long shelf. This shelf or tray extends the whole length of the movable beam, and moves or tilts with it when the balanced part

Digitized by Google

SIR WILLIAM THOMSON'S ELECTRICAL MEASURING INSTRUMENTS.

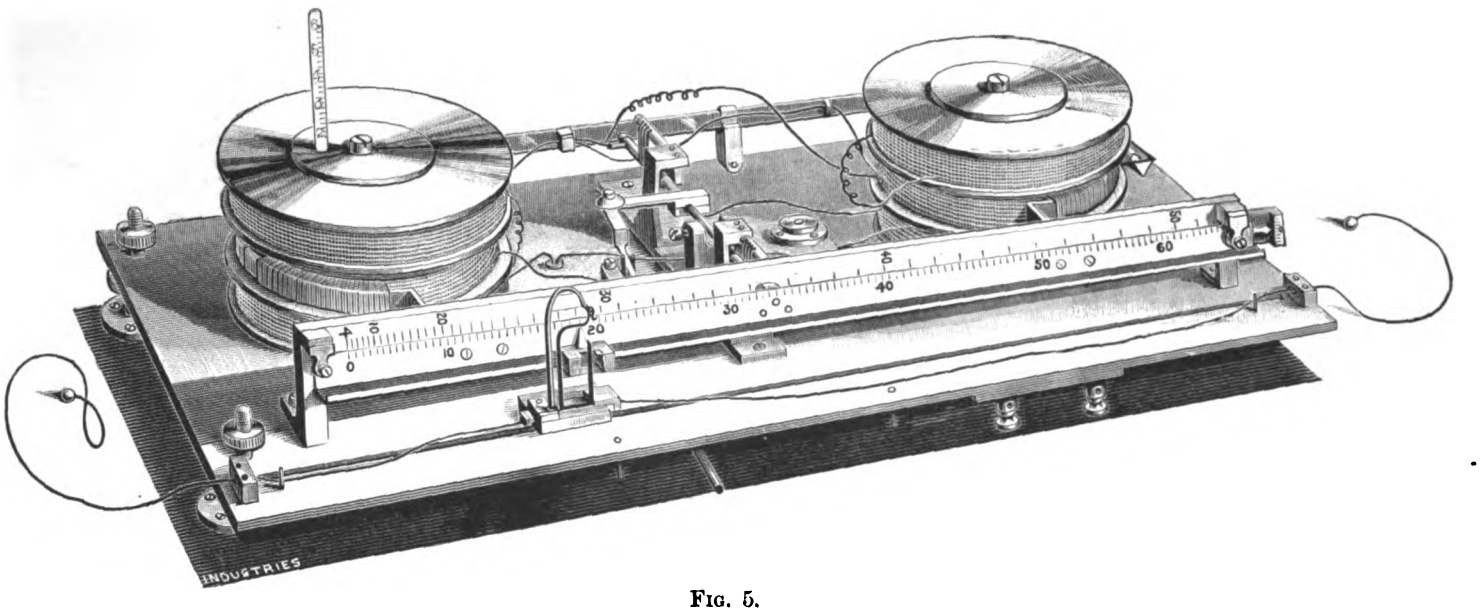

FIG. 5.

is displaced (see Fig. 1). At one end of the balanced part, at the extreme right of our illustration, is a small V shaped tray, in which a weight is placed. A standard weight is then placed at the opposite end of the shelf. This weight is of such form as to slide along the shelf easily (see Fig. 4). When placed at the zero position on the shelf it exactly balances the counterpoise in the V trough, and the balanced part should be in equilibrium when no current is passing. If it is not so, then a small adjustment can be made by means of a metal flag on the beam (Fig. 1), similar to that on a gravimetric balance. If the sliding weight on the shelf is moved along towards the middle the equilibrium is disturbed and a couple brought to bear upon the balanced part, which is proportional to the displacement of the sliding weight from its zero position. If a current is passed through the circuit, and the sliding weight displaced so as to restore the balance to its sighted position, the current strength is proportional to the square root of the distance by which the sliding weight has to be shifted in order to restore equilibrium. The shifting of this weight is performed by a very ingenious piece of mechanism, which will be understood from the enlarged view (Fig. 4). On the base board of the instrument, and just underneath the shelf on which the weight slides, is placed a little metal block, which carries a stout vertical wire extending a little above the shelf carried on the balanced beam. From the top of this wire is carried a pendant wire, which hangs down through a notch in the weight which slides on the shelf. This block, carrying the pendant, is pulled along the railway by a silk cord. When pulled it drags with it the weight on the shelf; but when the string is released the pendant returns to its vertical position and disengages itself automatically from the weight, leaving the balance free to tilt according to the direction of the forces acting upon it. By this means the weight can be shifted along until a balance is obtained, whilst at the same time the whole balance is covered with a glass case to protect it from currents of air. With each current balance three sliding weights and three corresponding counterpoises are provided, the weights being in the ratio of 1, 4, 16. Thus if with the ampère balance the lightest weight on the sliding tray in a certain position corresponds to a current of half an ampère through the instrument, the next weight at the same place corresponds to one ampère, and with the heaviest weight on it the current is two ampères. The upper edge of the shelf on which the weights slide is graduated into equal divisions, and the weight is provided with a sharp tongue of metal, in order that its position on the shelf may be readily and accurately determined. For the purpose of avoiding continual reference to square root tables, another fixed scale is placed behind the shelf, called the inspectional scale. On the upper edge of the shelf, along which the graduations are made, a small notch is cut at those divisions whose numerical denominations are exact squares; thus corresponding to divisions 1, 4, 9, 16, 25, 36, &c., on the scale engraved on the shelf are cut little notches in its upper edge. The inspectional scale is fixed close behind this, and yet not touching, and at those points on it exactly behind the notches are engraved numbers which are twice the square roots of the corresponding numbers on the shelf; thus corresponding to 1, 4, 9, 16, 25, &c., on the shelf the numbers 2, 4, 6, 8, &c., are engraved on the inspectional scale. Since the current passing through the balance when equilibrium is obtained with a given weight is proportional to the square root of the couple due to this weight upon the balance, it follows that the current strength when equilibrium is obtained is proportional to the product of the square roots of the weight used and of the distance of this weight from its zero position; but the inspectional scale is so graduated as to show at a glance the square root of the distance of the weight from its zero position, and hence the numbers on the inspectional scale indicate half ampères, ampères, or double ampères, according to the weight used.

The fixed inspectional scale shows approximately enough for many purposes the strength of the current; the notches in the top of the aluminium sliding scale or shelf show the precise position of the weight corresponding to each of the numbered divisions on the inspectional scale, and practically annuls error of parallax due to position of the eye. When the pointer on the weight is not exactly below one of the notches corresponding to integral divisions of the inspectional scale, the proportion of the space on each side to the space between two divisions may be estimated inspectionally with accuracy enough for all practical purposes. Thus, we may readily read off 34·2 or 34·7 by estimation, with little chance of being wrong by ·1 in the decimal place. But when the utmost accuracy is required, the reading on the fine scale of equal divisions must be taken, and the strength of the current estimated by aid of a table of square roots supplied with each instrument.

These general principles being understood, we proceed to describe the details of the several types of instruments adapted for various ranges of useful measurement. The range of each instrument is from 1 to 50 times the smallest current for which its sensibility suffices. The ranges of the different types of instrument regularly made are:—

The	Centi-ampère	Balance	from	1 to 50	centi-ampères
„	Deci-ampère	„	„	1 to 50	deci-ampères
„	Ampère	„	„	½ to 25	ampères
„	Deka-ampère	„	„	2 to 100	„
„	Hekto-ampère	„	„	10 to 500	„
„	Kilo-ampère	„	„	50 to 2500	„

Fig. 5 shows the general appearance of the centi-ampère, deci-ampère, ampère, and deka-ampère balances. In these instruments the outer diameter of the fixed coils is slightly greater, and the inner diameter less than those of the movable rings attached to the balance arms. The position of the movable rings when in equilibrium and equi-distant from the fixed ones above and below it, is a position of minimum force, and the sighted position for the sake of stability is above it at one end of the beam and below it at the other, in each case being nearer to the repelling than to the attracting ring by such an amount as to give about $\frac{3}{4}$ per cent. more than the minimum force. In order to adapt these balances for alternating currents, a special mode of arranging the conducting circuit has to be adopted. In the balances intended for alternate currents (which may be used also for direct currents) of from 5 ampères to 250 ampères, the main current through each circle, whether consisting of one turn or of more than one turn, is carried by a wire rope, of which each component strand is insulated by silk covering or otherwise from its neighbour, in order to prevent the inductive action from altering the distribution of the currents across the transverse section of the conductor; whilst to avoid induced currents in these parts the coil frames and base board are constructed of slate. The hekto-ampère and kilo-ampère balances are slightly different in arrangement from the foregoing. In these the whole current to be measured is passed through a single fixed ring and then divides through the two halves of a movable ring, which are urged, one up and the other down, by the resulting ampèrian force. The largest balance yet made is one for measuring currents up to 2500 ampères, constructed for Messrs. Paterson and Cooper. The centi-ampère balance (Fig. 5) is provided with a thermometer to test the temperature of its coils, and it may be used as a voltmeter when provided with platinoid resistance coils, which make it available for the measurement of potential difference from 10 up to 200 volts, or more.

The direct reading engine room voltmeter is an instrument based upon the same principle, but which indicates potential difference between certain limits without the

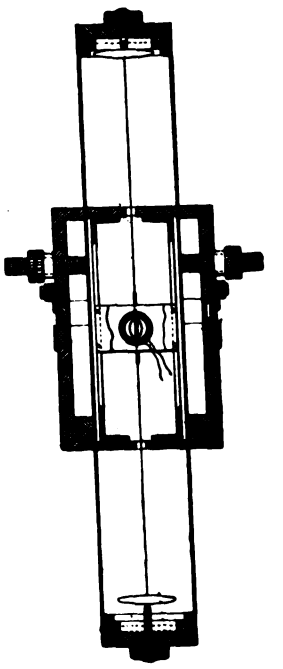

FIG. 6.

performance of any operation of weighing. This inspectional voltmeter (Fig. 7) consists of a fixed platinoid resistance, which is in series, with a fixed and movable ampère ring. On the base board of the instrument is fixed, horizontally, a single coil of highly insulated copper wire. Over this, and suspended parallel to it, is a movable coil, carried at the end of an aluminium rectangular frame, which is suspended by ligaments near the opposite extremity. The weight of the coil is counterbalanced by adjustable weights, so that its normal position is parallel to and a little removed from the fixed coil. When these three coils (viz., the platinoid resistance coil below the base board, the fixed coil, and the movable coil) are traversed by one and the same current, the electro-dynamic repulsion lifts the movable coil, and raises it slightly from the surface of the fixed coil, on which it rests when no current is passing. If the current through the coils is slightly

Digitized by Google

SIR WILLIAM THOMSON'S ELECTRICAL MEASURING INSTRUMENTS.

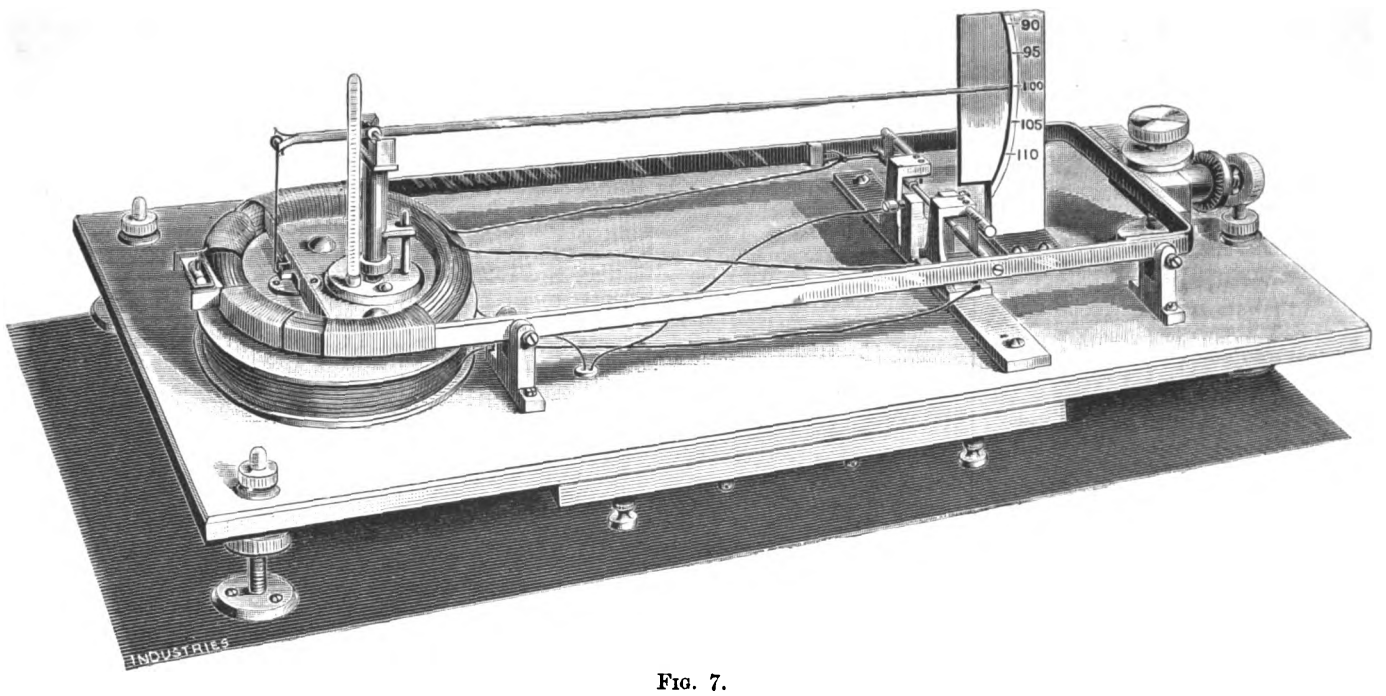

FIG. 7.

increased, the movable coil is repelled a little more; and if it is diminished, it is repelled a little less. These small movements of the coil are multiplied by a lever, the long arm of which moves over a scale, and the short arm of which is connected by a stiff wire with the balance bar carrying the coil. The fixed and movable ampère rings are each composed of many turns of fine insulated copper wire, having a total resistance of 100 ohms. The amount of added platinoid resistance depends on the potential to be measured in the ordinary use of the instrument. Thus for potentials of from 10 per cent. below to 10 per cent. above 100 volts the platinoid resistance is 700 ohms. The scale is divided so as to indicate directly in volts. The instrument is specially designed for use as an engine room voltmeter, and indicates directly, within allowable limits, the excess or deficit of e.m.f. from the normal. Temperature error is annulled by providing a thermometer, placed in the coils, and a set of compensation weights. Four weights, corresponding to centigrade temperatures 15°, 20°, 25°, 30°, are supplied, and when the thermometer indicates any atmospheric temperature between these limits, the weight most nearly corresponding to that temperature is placed in the V trough attached to the end of the balance bar on the left. When not in use, the weights are kept in little receptacles marked with the temperature, so that no mistake can be made in seeing which is in use.

The marine voltmeter (see Fig. 6) is an instrument designed for use at sea. The foregoing engine room voltmeter, and the deci- and centi-ampère balances, are not suitable for this purpose, as the mass of the moving part of the balance is too great. The marine voltmeter consists of a small oblate spheroid of iron, resembling a small round bean or flattened pea. It is attached to the middle of a platinoid wire, which passes through its equator, so that it is suspended with its equatorial plane vertical. If such an oblate is placed in a magnetic field, it will endeavour to place the plane of its equator in the direction of the lines of force of the field; and the couple required to hold it in any given position will depend upon the mass of the iron, and the form and strength of the field. In the marine voltmeter the magnetic field is created by a current circulating in a coil of copper wire in series with a set of platinoid resistance, variable according to the potential to be measured. The platinoid wire carrying the oblate is stretched by attaching it to the ends of a tubular support, whilst the oblate carries a pointer which moves over a dial. The magnetic field due to a current in the coil is a uniform field, and the zero portion of the oblate is, with its equatorial plane, inclined at an angle of about 45° to the lines of force. The platinoid wire bearing it is arranged so that its torsion tends to turn it into a position at right angles to the lines of force. This tendency is resisted by a stop against the needle, so placed that when no current, or any current less than 90 milliampères is passing through the instrument, the needle remains at the end of the scale. When a current exceeding 90 milliampères is passing through the instrument, the e.m.f. operates against the torsion, and turns the oblate into a definite position in the field. The position of the oblate is thus a measure of the current passing through the instrument, and hence of the potential difference at the terminals of the coils. When the mean potential difference to be measured is 100 volts, the platinoid resistance is adjusted to make up with the fine copper wire solenoid, the resistance of which is about 60 ohms, a total resistance of 1000 ohms. Thus the direct reading of potential on the scale is in volts.

Another instrument for use in electric light installations is the adjustable magneto-static current meter and lamp counter. This instrument is a convenient modification of the well known graded galvanometers. It is a direct reading galvanometer, and has certain advantages over the electric balances in portability, and in being direct reading through a continuous range of from 1 to 90 or 100 times its smallest current, which may be anything from half a milliampère to one ampère, according to the number of turns in the coil supplied with the instruments. The general design of the instrument may be described as follows: Underneath a circular dial plate are fixed a pair of semi-circular coils, which may consist of many

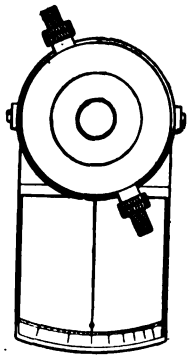

FIG. 8.

turns of wire or of a massive copper bar, according to the strength of the current to be measured. Centrally beneath the dial plate is a short glass tube, in which is suspended a circular disc of magnetised steel. The suspension of this disc is very ingenious. On the surface of the dial plate is fixed a piece of platinoid spring, and from this depends, by a short cocoon fibre, an aluminium needle, which is carried on the same vertical axis as the magnetised disc. If the cocoon fibre were attached to some rigid support any shaking of the instrument would be certain to break it; but suspended as it is from a yielding and flexible support, any jolt or shake causes the spring to yield sufficiently to let down the needle on to the dial plate, and so saves the cocoon fibre from fracture. Underneath the coils is attached a permanent magnet, which creates the controlling field. The instrument thus virtually consists of a galvanometer with a powerful controlling field, and in this respect it has all the disadvantages of this class of apparatus: in not being available for alternate currents, and in that the value of the deflections is dependent upon the permanence of a steel magnet. With a good quality of steel and a proper ageing of the magnet (by heating it several times in boiling water and cooling it again, and subjecting it to somewhat varied rough usage), a very nearly permanent condition is reached, and its magnetism will probably remain constant from year to year. Still it can never be relied upon as absolutely constant, and hence the magneto-static instruments require from time to time to be re-adjusted by the aid of a balance instrument, the adjustment consisting in shifting the controlling magnet. The scale has one hundred divisions, corresponding to equal differences of tangents of the angle between the magnetic axis of the needle and the electromagnetic axis of the rings. The divisions may be numbered from 0 to 100, but for many purposes it is convenient to number them from 30, 20, or 10 on the left of zero, and from zero to 70, 80, or 90 on the right; because we have thus larger divisions in the neighbourhood of the zero than when it is taken at the extreme left of the scale, and because it is sometimes convenient to measure small currents in the direction opposite to that of currents ordinarily measured. The scale being so divided that its divisions indicate equal increments of current through the coils, it is possible to set the magnet beneath the coils, so that the unit of current shall be within certain limits of what is desired. It may, for example, be one milliampère, one ampère, or a tenth of an ampère; or, more convenient still, it may be made equal to the average current through a lamp on the installation in connection with which the instrument is used. It becomes thus a lamp counter, and when put on the circuit shows at once the number of lamps in actual use at that instant. The instrument may be made with such massive coils as to count lamps up to a thousand or more. When the instrument is used as a lamp counter, primary adjustment or re-adjustment can be performed at any time with great ease by turning the screw platform which bears the adjusting magnet, so as to raise it or lower it until it is found that the deviation from zero produced by the current of any number of lights shows a corresponding number on the scale of the instrument. With scales numbered from 1 to 90, any number of lamps within these limits can be directly counted by inspection; and for greater numbers of lights the instrument can be set to count by five or by ten, so that the attendant knows at any instant the load on his dynamo by simple inspection. The instrument must be, however, removed as far as convenient from the neighbourhood of the dynamo, or else calibrated in the position in which it is to be used. The most convenient instrument of the complete series for an ordinary installation or workshop would be the deci-ampère balance, which measures from about $\frac{1}{10}$ to 5 ampères, and a magneto-static galvanometer reading from 1 to 100 ampères. The magneto-static instrument can then at any time be re-adjusted by the aid of the balance. This is simply performed by placing the instruments in series on a circuit and passing a current of 5 ampères through them. The current should be adjusted until the deci-ampère balance indicates exactly 5 ampères, and then the magneto-static instrument set by raising or lowering its controlling magnet until its needle points exactly to 5 on the scale

Digitized by Google

when the current is on, and to the zero of the scale when the current is off. At the last meeting of the British Association Sir William Thomson stated that the balance instruments have a sensibility of one-tenth per cent. over a range of something like 1 to 25 times the smallest current they are designed to read; but it should be understood that the balances may be used for double these currents with a slight sacrifice of accuracy.

THE PARNELL-SIMPSON PROCESS.

We have already referred to this process as one recently brought out for the recovery of sulphur from alkali waste in combination with the ammonia-soda process. Ever since the Leblanc soda process was established, the insoluble residue left in the vats after lixiviation of the black ash balls has proved a source of annoyance and expense to the manufacturer, and an offensive nuisance to the neighbourhood. Besides this, the sulphur used in the process, and obtained from pyrites or brimstone, is lost almost entirely in this residue, which is usually termed alkali waste. Numerous have been the attempts to utilise this waste, or at least to extract the sulphur from it in a usable form, and though some manufacturers have worked several distinctly different methods for long periods with more or less success, there has never yet been devised a process which has commended itself to the main body of soda makers. The most promising have been those proposed by Ludwig Mond, by Schaffner and Helbig, at Aussig, by P. W. Hofmann, at Dieuze, and by Chance Brothers, near Birmingham; but these have not yielded results commensurate with the expectations reposed in them. Various causes have contributed to this: increased value of hydrochloric acid, the difficulty in the treatment of sulphuretted hydrogen (especially when diluted with carbonic acid and nitrogen), the incomplete reaction of sulphurous acid on sulphuretted hydrogen, and the exceedingly low price to which Spanish pyrites have fallen per unit of sulphur. The tank waste amounts to from 1½ to 2 tons per ton of soda ash produced, and consists chiefly of calcium monosulphide when in the fresh damp state. This, when piled in heaps, changes by the action of the oxygen and carbonic acid in the air with production of heat, and also eventually sulphuretted hydrogen, and soluble sulphides and hyphosulphites of calcium, which latter are washed out by the rain and pollute the water courses. Thus it is very desirable for the general comfort that some useful outlet should be found for this troublesome substance, and with this object in view Messrs. Parnell & Simpson have taken out a series of patents, in which they propose to make use of the waste in quite a new way, and which, if it prove as successful as its inventors predict, will give a new lease of life to the Leblanc soda process.* Their method is embodied in Patent No. 381, 12th January, 1885, and is elaborated and improved upon in numerous other patents, viz., No. 1937, 12th February, 1885; No. 8440, 13th July, 1885; No. 7657, 24th June, 1885; No. 14364, 24th November, 1885; Nos. 46 and 47, 2nd January, 1886; and No. 14711, 13th November, 1886. There are also several other patents, which have not yet been published, bearing on the same matter.

The *rationale* of the process is as follows, as contained in their first patent, viz.: Fresh alkali waste is treated in a closed vessel with a solution of ammonium chloride and boiled, whereby sulphide of ammonium is driven off in the gaseous state, and a solution of chloride of calcium is left in the vessel, which may be run to waste. The ammonium sulphide is conducted into brine, and this is treated with carbonic acid gas. The sulphide of ammonium is decomposed, forming carbonate and eventually bicarbonate of ammonia, and sulphuretted hydrogen is driven off and collected in a gas holder and utilised for making sulphur or vitriol. The bicarbonate of ammonia left in the brine reacts on the salt, forming bicarbonate of soda, which is precipitated, and chloride of ammonium in solution. The precipitated bicarbonate is separated by filtration, and the chloride of ammonium used over again for the treatment of fresh alkali waste. The inventors find that it is necessary to use very pure carbonic acid gas for this process, or otherwise the sulphuretted hydrogen would be too much diluted with nitrogen, and suggest procuring it from limestone heated to redness in iron retorts with a jet of steam. They also find that if the waste is heated with an excess of dilute ammonium chloride solution the ammonium sulphide is not driven off as such; but during the first period of heating a considerable quantity of sulphuretted hydrogen in the free state is given off, and during the last period ammonia is predominant. They therefore collect this sulphuretted hydrogen by passing the gases through a condenser, where the sulphide of ammonium and free ammonia are condensed, leaving a gas containing only sulphuretted hydrogen and slight traces of ammonia, which are taken out by passing through an acid tower. This gas is taken to a gas holder for use. It is stated that as much as 50 per cent. of the suphuretted hydrogen given off from the waste can be recovered in this way. They assert in this patent that in a works where carbonate of soda is produced in about equal quantities by the Leblanc and by the ammonia process, the sulphur required may be recovered for repeated use or sale; the expense of moving the waste is avoided, an offensive nuisance obviated, lime is saved, that from the lime kiln may be used for bleaching powder or caustic, and the vitriol made from the sulphuretted hydrogen will be very pure. In their second patent, No. 1937, they merely propose a means for the better recovery of the ammonia and sulphuretted hydrogen. They cause the gases from the treatment of alkali waste with ammonium chloride to pass through a coke tower, down which acid sulphate of ammonium is running. This decomposes the ammonium sulphide, forming neutral sulphate of ammonia and free sulphuretted hydrogen, which is collected in a gas holder after passing through an acid tower, to absorb any ammonia which may be carried over. The neutral sulphate of ammonia is boiled down in a lead vessel to dryness, and the dry sulphate heated in a cast iron vessel until the surplus of ammonia is driven off, forming again the acid sulphate, which is dissolved and used over again in the tower. The temperature in the iron vessel must not exceed 800° F., or some ammonia may be decomposed. It is preferred to bring steam in contact with the heated sulphate, as it helps the evolution of ammonia, and keeps the temperature more regular. They also propose to use sulphates of the alkalies, adding them to the ammonium sulphate before boiling down, by which an increased yield of ammonia is obtained. In their next patent, No. 7657, they appear to have found a difficulty in obtaining the sulphuretted hydrogen sufficiently pure by any of the means formerly proposed, and therefore this patent is for "Improvements in the separation of sulphuretted hydrogen from nitrogen."

There is no doubt that the patentees found that their method of using bisulphate of ammonia was impracticable, and also that it was highly difficult and expensive to obtain pure carbonic acid, and therefore they resolved to abandon the former, and obtain their carbonic acid from the ordinary lime kiln, which is of course very dilute (containing only from 25 to 30 per cent. CO_2), and necessarily providing sulphuretted hydrogen largely contaminated with nitrogen. Therefore this patent, which is as follows: A solution of ammonium sulphide is treated with carbonic acid gas from a lime kiln, whereby carbonate of ammonia is formed, and sulphuretted hydrogen driven off, diluted with a large amount of nitrogen and some carbonic acid. This dilute gas is then taken through a tower filled with cokes, down which monosulphide of ammonium in solution is flowing. This takes up the sulphuretted hydrogen from the gas forming sulphydrate of ammonia according to the equation

$$(NH_4)_2S+H_2S=2NH_4HS.$$

The temperature in this tower should not exceed 70° F. The solution of sulphydrate of ammonia is boiled or subjected to a partial vacuum, whereby the sulphuretted hydrogen absorbed is given off in the pure state, and which, after passing through a condenser to an acid tower, may be taken to a gas holder for use. Monosulphide of ammonium is left in solution after the boiling, and may be cooled and used over again, or, according to the drawing with the specification, it is distilled before again entering the cycle of operations. A patent No. 8440 was completed earlier, though filed provisionally after the one just mentioned. It is proposed to treat the sulphide of ammonium solution with sesquicarbonate of ammonia in a closed vessel with a steam coil or jacket, or to employ a vacuum; monocarbonate being thus formed, and sulphuretted hydrogen set free. This is washed in sulphide of ammonium or of the alkali metals to take out any trace of carbonic acid, and taken through an acid tower to a gas holder. The monocarbonate is treated with lime kiln or other carbonic acid gas, and fresh sesquicarbonate produced. The monocarbonate may be also used in the ammonia-soda process, or for treating alkali waste; if for the latter, the sesquicarbonate solution may be very weak, say 5 per cent.; but if for the former it should be as concentrated as possible, even with crystals of bicarbonate formed in it. The crystals dissolve in the sulphide of ammonia. They prefer to use two equivalents of sesquicarbonate to one of sulphide of ammonium, or a slight excess over this of sesquicarbonate.

In patent No. 14364 they refer to the production of sulphuric acid from a mixture of sulphuretted hydrogen and sulphurous acid gases. They point out that hitherto the yield from this combination has been much less than that given in theory, and that this is generally accounted for by the formation of pentathionic and other sulphur acids. To obviate this it has been proposed to conduct the process in the presence of chlorides of calcium or magnesium; but this has not been attended with any satisfactory results. The inventors therefore propose to carry on this reaction in the presence of vitriol, of say 15° Tw. to 20° Tw., and preferably at about 100° F. The vitriol is run down a tower, up which the mixed gases are caused to travel, and by this means all sulphur acids are absorbed by the vitriol, which yields, on boiling, sulphur, sulphurous acid, and sulphuric acid. The sulphur, together with that from the reaction between the sulphurous acid and sulphuretted hydrogen, is separated by subsidence, washing, and filtration, and the sulphurous acid is used over again. The excess of sulphuric acid formed by the decomposition of the thionic acids can be withdrawn from the vitriol from time to time. The tower is leaden, filled with flints. The boiling of the vitriol takes place in leaden pans, with a steam coil or jacket.

Their next patent, No. 46, 1886, is devoted to the production of pure carbonic acid gas, which is accomplished as follows: Monocarbonate of ammonia is treated with carbonic acid from lime kiln or other well known source, forming thereby bicarbonate of ammonia in crystals. The temperature must not rise above 70° F. These crystals are heated in a small amount of their mother liquor in a closed vessel to 165° F., whereby the carbonic acid is liberated in the pure state, leaving monocarbonate behind for re-use. The monocarbonate solution contains from 25 to 30 per cent. $(NH_4)_2CO_3$, and may be carbonated in a Solvay tower. Drawings are given, as the inventors aver that this mode of obtaining pure carbonic acid will be of use in very many manufactures. No. 47 aims more than the former ones at combining the ammonia soda process with this recovery of pure sulphuretted hydrogen. They treat waste with ammonium chloride solution, and lead the ammonium sulphide into water or weak ammoniacal solution in a closed vessel until it contains from 8 to 10 per cent. ammonia. This solution is treated with carbonic acid as pure as possible, obtained as in No. 46, preferably in a Solvay tower, bicarbonate of ammonia being precipitated, and sulphuretted hydrogen nearly in the pure state being given off. This is washed, to arrest any CO_2 and NH_3, and conducted to a gas holder. The bicarbonate of ammonia is agitated with brine, forming bicarbonate of soda and chloride of ammonium, which latter is used over again to decompose fresh waste. The inventors claim the following: (1) Decomposition of ammonium chloride by waste or other material containing sulphide of calcium; (2) absorption of the sulphide of ammonium by water or weak ammoniacal solution (this weak solution is obtained from the towers after the precipitation of the bicarbonate of ammonium, and consists of carbonate and sesquicarbonate of ammonium); (3) decomposition of sulphide of ammonium in solution by carbonic acid, forming bicarbonate and sulphuretted hydrogen; (4) removal of bicarbonate of ammonium and employment for making alkali; (5) addition of ammonium sulphide solution to compensate for ammonia removed as carbonate or bicarbonate. In their next patent, No. 14711, the patentees appear to have given up the idea of producing sulphur by means of the reaction between sulphurous acid and sulphuretted hydrogen, and their invention consists in apparatus for regulating the air supply in order to burn the sulphuretted hydrogen, producing either sulphur or sulphurous acid according to the equations $H_2S+O=H_2O+S$ and $H_2S+3O=H_2O+SO_2$. This is done by means of an ingenious arrangement of vessels attached to an oscillating beam and suspended therefrom in water. By the oscillation of this beam, air and sulphuretted hydrogen are drawn into the vessels, the quantity of each being regulated by moving the vessels along the beam towards or away from the fulcrum. The air and gas are forced out in the same way to the burners or furnace. For producing sulphur five volumes of air to two of H_2S are necessary, and for sulphurous acid eight of air and one of H_2S. If vitriol is to be made, the proportion is ten to one. The water may be covered with blue oil to prevent absorption.

With regard to the commercial value of this process, a few remarks will not be out of place. Presuming that the operations are as successful as the inventors expect, and that the combined Leblanc and ammonia-soda works are capable of turning out a quantity of soda ash divided equally between the two processes, first of all will be saved all the lime now used in the ammonia process, amounting to about 14cwt. per ton of ash made, or 8s. 9d. in value. Again, for each ton 58 per cent. ash made by the Leblanc process, a quantity of waste containing about 7·4cwt. of sulphur is produced; and if 90 per cent. of this is recovered, that is, 6·63cwt. of sulphur (pyrites 49 per cent. being worth about 16s. 4d. per ton for sulphur), this 6·63cwt. is worth about 11s. There is also saved the cost of removal of the waste, amounting to about 3s. per ton on the ash. Therefore we have a saving to the ammonia process of 8s. 9d. per ton 58 per cent ash, and in the Leblanc process of 14s. per ton 58 per cent. ash, and since

*Messrs. Schaffner & Helbig proposed in 1882 to combine the Leblanc and ammonia-soda processes by treating the ammonium chloride liquors from the latter with magnesia, distilling off the ammonia and adding waste to the solution of magnesium chloride left, thereby producing sulphuretted hydrogen, magnesia, and calcium chloride. The magnesia is left ready for use again.

Digitized by Google

the quantity of ash made by each process is the same, the result is a saving of 11s. 4½d. on each ton of ash made. Against this saving of 11s. 4½d. per ton of ash there are the following expenses: The extra cost incurred in treating the ammonium chloride liquors with waste over the same with lime, as there is 18 or 20 per cent. of insoluble matter in the waste which must be removed from the decomposing vessel; the cost of filtering the ammonium bicarbonate (made to produce pure carbonic acid), of heating this bicarbonate, collecting, and then forcing this carbonic acid through the ammonium sulphide liquors, also collecting the sulphuretted hydrogen, and freeing it from carbonic acid and ammonia; treating the sulphuretted hydrogen with sulphurous acid and collecting the sulphur, also the production of the sulphurous acid and increased loss of ammonia over the ordinary ammonia process. These expenses would in all probability be amply covered by the 11s. 4½d. before mentioned, and if the recovered sulphur could be produced without much extra cost in such a form as to compete with Sicilian brimstone, there would be added to this a further working margin of from 17s. 9d. per ton on the total ash made, taking brimstone as worth £5. 17s. 6d. per ton.

This process, therefore, seems to have substantial prospects, and should it prove workable it would do much to encourage the drooping spirits of the Leblanc soda makers. The Leblanc process can still make caustic soda, which the ammonia process cannot do (at least, at a profit), and with that and the bleaching powder it should manage, even without the sulphur recovery process, to hold its own. But there are signs that in the near future this staff, on which the old soda process has been leaning so long, will be removed, and that bleaching powder will be made from the residual ammonium chloride liquors of the ammonia process. It is a fact that MM. Pechiney, at Salindres, can produce chlorine from their magnesium chloride liquors (obtained in their salt gardens) at a price equal if not lower than it can be produced by Leblanc soda makers, and therefore the only difficulty seems to be in the decomposition of the ammonium chloride liquors by means of magnesia to form a not too dilute solution of magnesium chloride. This seems a difficulty to be easily surmounted after those which MM. Pechiney & Cie. have conquered.

We are also threatened with entirely new processes for making soda and chlorine directly from common salt. Of course, if any of these are successful, both the Leblanc and the ammonia-soda processes may hide their heads. But until either bleaching powder can be made by the ammonia-soda process sufficiently cheaply, or the whole trade is revolutionised by some new process, this means for the recovery of sulphur by Messrs. Parnell & Simpson may fill up the gap, and bring more grist to the mill of the alkali trade.

A NEW OXYHYDROGEN LIGHT.

An application of the oxyhydrogen light to general illumination purposes has been introduced by Messrs. Georges Delaporte & Co., of Paris, and was recently on view at Dashwood House, 9, New Broad-street, London. In this application a special burner is employed, in conjunction with an ordinary gas burner. In the case of Argand burners, the special burner is placed in the centre of the ring of lights; in the cases of fishtail or batswing burners, the special burner is placed close to the ordinary burner. The supply of gas to either of the burners is controlled by a three-way cock, the turning of which determines whether ordinary or oxygen gas is to be used, or the light extinguished altogether. The difference between the two lights is very striking, the change from the dull light of the ordinary gas to the brilliant illumination of the oxyhydrogen allowing colours which are not distinguishable by the former to be readily distinguished by the latter. For the production of the oxyhydrogen light, oxygen and ordinary gas are burnt together in the special burner, the best results being obtained when the ordinary gas is carburetted, which is done by passing it through gasolene. Messrs. Delaporte & Co. employ steel reservoirs 8ft. long by 5in. diam., with hemispherical ends. The oxygen is forced into these under a pressure of about 120 atmospheres, each reservoir containing gas equal to 125 cub. ft. of gas at atmospheric pressure, the supply being stated to be sufficient for one burner for 125 hours. The reservoirs are charged at Brin's Oxygen Company's Works, Westminster (see *Industries*, Vol. III., page 457), and as they become exhausted are changed for others fully charged. The light of one special burner is said to be equal to that given by seven Argand burners, each burning 5 cub. ft. per hour; and the consumption of 28 cub. ft. of carburetted gas with 16 cub. ft. of oxygen is stated to equal in illuminating power 140 cub. ft. of ordinary gas.

The system requires two sets of pipes, one to carry oxygen from the reservoir to the burners, and the other to convey ordinary gas. When carburetted gas is used, a third pipe is necessary in addition. The idea of the firm introducing this method of using oxyhydrogen gas, or "electric gas," as they call it (which, by the way, is a misnomer, as it has nothing whatever to do with electricity), is that many large shops and houses whose proprietors do not care to incur the expense of dynamos, steam engines, and boilers, are desirous of having a better light than the ordinary gas gives them at special times, and that a system which enables them to change quickly from cheap, economical gas to a brilliant light equalling the electric light, will find favour. Whether this advantage is sufficient is open to doubt, as the expense of duplicate or triplicate pipes must be considerable. The changing of reservoirs must also be a costly item, besides entailing a certain amount of inconvenience which, we think, many consumers might object to. We shall watch with some interest the introduction of this system of illumination, should the promoters be successful in establishing it in this country beyond the experimental stage. We are informed that it is being introduced with success in Paris.

Notes.

AMERICAN RAILWAY BRIDGES.

One of the characteristics of the railways of the United States is the large number of accidents which occur annually by the failure of bridges. In a review on the past year, the *Railroad Gazette* of New York states that the railway companies, as a body, have not only improved their permanent way, but largely substituted iron and stone for wood in bridges. Our contemporary continues: "The year has been remarkable for the number of short spans replaced by plate girders or iron trusses. This is one of the most important changes in practice. The long span bridges are reasonably sure to be built with some approach to the best usage, and it is the little ones that are most pernicious. A further notable advance in this direction is that of the Pennsylvania Railroad Company in the use of stone arches for short spans."

MINING IN VENEZUELA.

The richest mining properties in Venezuela are the gold mines in the State of Bolivar and the copper deposits in the State of Lara. The United States Consul at La Guayra states that gold and silver are also found in the States of Carabobo, Lara, and Bermudez; gold, copper, and kaolin in the State of Guzman Blanco; coal, pitch, and sulphur in the States of Zulia and Bermudez, and petroleum in the State of Los Andes. There is also a pitch lake at the mouth of the Pedernales River, on the Gulf of Paria, that is quite as extensive and valuable as that of the island of Trinidad. All these mineral deposits are as yet undeveloped, except the gold of Bolivar and the copper of Lara. The gold mine "El Callao," Guayana, State of Bolivar, is, so far as is known, the only important and valuable one, which, from its opening in 1871 to 1884 inclusive, has yielded £2,961,585. In the latter year the product amounted to the sum of £659,141. No later statistics can be obtained, but its reputation is fully maintained. The copper mine of Aroa, State of Lara, like the "El Callao" mine, is directed by an English company, and the ore is exported to Swansea. The only available information shows that from 1880 to 1883 inclusive the product amounted to 75,200 tons of ore, of the value of £622,925. The yield from October 1st, 1883, to September 30th, 1884, was 26,261 tons.

A NEW STORAGE BATTERY.

M. Carrière has taken out a patent in France for a new method of constructing the electrodes of storage batteries. The object of his improvement is to reduce the weight of lead required for a given capacity, and to make the plates absolutely rigid, so that no short circuit can occur through buckling. In his patent the inventor points out that in batteries of light weight the lead frame of the plates must necessarily be mechanically weak, and if made sufficiently thick to resist transportation and rough usage, the battery becomes too heavy. Moreover, the frame is continually subject to oxidation, and just when the battery gets into the condition of maximum capacity the plates are near mechanical destruction. Whatever may be the scientific value of these arguments, the inventor has certainly produced an ingenious combination, which is not open to the same objections, though perhaps practical use may reveal other and possibly more important faults. The support of the active material in M. Carrière's battery is formed of carbon plates. The material of the plate need not be pure, and, in fact, the inventor uses a mixture of two parts of common retort carbon and one part of lamp black or charcoal ground up together, and mixed with a little flour paste. The plastic mass is rolled into slabs, cut into the desired form with a projecting tag for the connections, and then baked at a temperature of 1300°C. After this it is slowly cooled, and both sides are covered with a layer of litharge from 1 to 1½ millimetres thick. By a peculiar process the litharge is made to adhere firmly to the surface of the carbon plates. The inventor claims that these batteries require no process of forming, and give a current after the first time they are charged; also that the supports are mechanically perfect, and are not attacked by the acid solution, whilst the whole of the lead is actually available for storage.

THE ALUMINIUM COMPANY, OLDBURY.

The works at Oldbury, near Birmingham, for the manufacture of aluminium and sodium on a large scale, by the Castner process, are rapidly approaching completion, and it is expected that sufficient progress will have been made to start about March 1st. The works cover an area of six acres, and are calculated to give employment to a hundred men, working night and day. They adjoin Messrs. Chance Brothers' alkali works, and the muriatic acid required in the Castner process will be delivered by a pipe from the alkali works direct to the aluminium works, whilst the caustic soda employed in the production of sodium will also be obtained from Messrs. Chance's works. Thus on two of the materials for the manufacture there will be no carriage to pay. The whole of the fuel employed will be gas, made in eight of Wilson's gas producers. The furnaces, of which there are forty, are calculated to produce 300lb. of aluminium and 1000lb. of sodium per day; but as 900lb. of sodium are required to produce the aluminium, there will only be 100lb. of sodium available for sale. The aluminium will be produced in pigs, weighing about 2½lb. each. As the present production of aluminium is probably only about 100lb. per day, it will be seen that the Aluminium Company are taking time by the forelock in endeavouring to be prepared for the increased demand which will follow on the reduction in price of this metal. In the production of aluminium bronze for telegraph and telephone wires, and in the manufacture of "Mitis" wrought iron castings, and in producing soundness in steel ingots, the use of aluminium has probably a future before it. Plant for the manufacture of chlorine by the Weldon process is also being erected on the works.

BASIC STEEL ABROAD.

The statistics of the production of steel and ingot iron from phosphoric pig in the year ended 31st October present two salient facts which cannot fail to arrest attention. First we have the unquestionable evidence of officially verified figures to prove that the basic process is making constant and rapid progress; and, next, we learn from the same source that our rivals abroad are making much better use of the process than we. The total production of Europe in the year 1886-87 amounted to 1,702,252 tons, against 1,313,631 tons in 1885-86, an increase of 29·6 per cent. But of the former quantity Great Britain produced only 364,526 tons, or scarcely more than one-fifth, a relatively insignificant quantity when we regard it in connection with the total make of iron in this country. The production of Germany, Luxemburg, and Austria is given as 1,102,496 tons; but as the output of the two latter countries is very small, it is practically the make of Germany which is presented in these figures. Thus absolutely the Germans have made in the last year some three times the quantity of basic steel that we have produced, while relatively the difference is much greater in favour of our Teutonic rivals. The question which naturally suggests itself is—Who is at fault in this matter? Clearly we must have a good reason for neglecting this process, or we must admit that our foreign rivals are more apt than we are to profit by the discoveries of science, and that they have stolen a march upon us to our serious disadvantage. Probably the only legitimate reason we can assign for our rearward position in this matter is the action of Lloyd's in condemning basic steel for shipbuilding on account of the imperfections which revealed themselves in the product in the early days of the manufacture. This condemnation was doubtless a serious obstacle to the development of the process. The obstruction, however, no longer exists, the report of their surveyor and that of the Admiralty, on which we commented some time ago, having practically withdrawn the condemnation. We see already the stimulating effects of these reports in the latest statistics issued, which show the increase in the out-put of basic produce in the year to be 41 per cent. for England and only 27 per cent. for the rest of Europe. In comparing these figures, we must bear in mind that 41 per cent. represents for us only 106,060 tons, while 27 per cent. for the rest of Europe amounts to 282,561 tons. The advantages of being enabled to utilise our phosphoric ores cannot be less for us than for our neighbours, and it is certain that if we are to keep the lead in the iron trade, we cannot afford to be wasteful of our opportunities.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

13th January, 1888.

535. Brown, J. ..... Screw gill machines.
536. Clegg, A. ..... Underpick looms.
541. Gill, J. E. ..... Mechanical navvies.
543. Rawstron & Chapman. Sewing machine.
545. Turner, C. ..... Chaff cutters.
580. Sack, H. ..... Rolling mills.
581. Thickpenny, T. E. ..... Washing machines.
585. Hoeborn, H. ..... Paper making machines.
587. Becker, W. ..... Casting of metal ingots.

14th January, 1888.

594. Thwaite, B. H. ..... Steam generators.
597. Moulton, G. ..... Engraving machines.
600. Johnson, J. Y. ..... Hot air engine (*Genty*).
612. Wright, S. ..... Machine for shaping heads of casks.
619. Böttcher, E. ..... Sewing machines.
620. Böttcher, E. ..... Sewing machines.
629. Mayer, M. ..... Calculating machines.
632. Mannlicher, F. ..... Magazine fire arms.
634. Parker, W. W. ..... Lifeboat.
636. Simpson, W. S. ..... Movable crucible for conveying molten glass.
638–9. Pinkney, C. W. ..... Punching, riveting, and shearing machines.

16th January, 1888.

645. Mathieson, J. ..... Looms.
651. Parker, J. B. ..... Edge planing machines.
653. Evans, R. ..... Machine guns.
654. Marshall, J. ..... Looms.
655. Skipton & Rhodes ..... Coal getting machinery.
656. Hargreaves, J. ..... Thermo-dynamic engines.
660. Briggs, J. W. ..... Rotary pumps and engines (*Barber*).
669. Ide & Love ..... Machinery for rolling and figuring glass.
681. Lake, H. H. ..... Type writing machines (*Allen*).
685. Watson & Starkey ... Machines for pressing vegetable matter.
686. Lake, H. H. ..... Casting of metal ingots (*Illingworth*).
688. Abel, C. D. ..... Gas motor engines (*Gas Motoren Fabrik*).
680. Aniello, J. A. ..... Lifeboat.

17th January, 1888.

699. Hay, W. ..... Machinery for the manufacture of groats.
701. Stuart, H. A. ..... Driving mechanism to obtain continuous rotary motion.
710. The Arracan Company and Dale ..... Rice hulling and cleaning machinery.
716. Noble, J. ..... Regenerative furnaces.
719. Boult, A. J. ..... Mining machines (*Westbrook*).
721. Thompson, W. P. ..... Roller mills (*McAnulty*).
725. Hearn, M. ..... Type writing machines.
730. Weidenbusch, A. ..... Machinery for making paper bags.
731. Rickard & Rickard... Tip waggons.
745. Brab, A. ..... Manufacture of casks or barrels from paper.
749. Lake, H. H. ..... Spooling machines (*Wilkins*).
755. Stubbs & Stubbs ..... Winding yarns or threads.
756. Prenez, J. E. ..... Apparatus for treating crushed grain.

18th January, 1888.

763. Watts, W. ..... Wire rolling.
764. Munro, G. ..... Hydraulic apparatus for testing the working pressure of steam boilers.
766. Anderson, A. ..... Sewing machines (*Singer Manufacturing Co.*).
768. Duncan, R. ..... Bending iron or steel bars.
773. Justice, P. M. ..... Triple expansion steam engines (*Davidson*).
774. Yeadon, J. ..... Loom reeds.
775. Willis, J. ..... Improved steam wheels as motors.
776. Bowman, W. ..... Propulsion of ships.
777. Smith, G. ..... Machines for combing wool.
783. Smith, J. ..... Gas engines.
787. Myers, F. ..... Machines for forming the heads of nails.
790. Blum, J. ..... Rotary engine.
792. May & May ..... Self acting mules.
793. Webster, G. T. ..... Mitre planing machine.
794. Pickles, J. H. ..... Apparatus for punching holes through the crowns or sides of hats.
807. Hacking & Hacking ... Rag engine.
814. Jensen, P. ..... Manufacture of plates of copper. (*Martin*).
818. Anderson, W. ..... Disappearing mountings for guns.
824. Sharpe, A. H. B. ..... Apparatus for drying leaves of the tea plant.

19th January, 1888.

831. Baird, R. ..... High pressed steam engines.
844. Lindley, H. ..... Compound steam engines.
846. Groth, L. A. ..... Knitting machines (*Grosser*).
856. Herbertz, F. A. ..... Furnaces.
859. Struthers, A. ..... Cloth steaming machines.
863. Bernhardt, G. ..... Spinning machines.
869. Hooper & Moore ..... Polishing and grinding machines.
872. Simon, H. ..... Circularly moving sieves.

ELECTRICITY.

13th January, 1888.

549. Blackburn, J. ..... Dynamo-electric generators.
584. Madgen, W. L. ..... Electric railways.

14th January, 1888.

609. Berghausen, A. ..... Apparatus for determining the poles of electrical circuits.
616. Brookes, A. G. ..... Phonographic apparatus (*Jacques*).
623. Gülcher, R. J. ..... Thermo-electric piles.
633. Coerper, C. ..... Dynamo-electric machines.

16th January, 1888.

664. Lovett, F. J. ..... Electrical lamp for bicycles.

17th January, 1888.

698. Cornthwaite, R. ..... Electric lamps.
705. Percy, L. E. ..... Telephone mouthpiece.
713. Coad, T. ..... Galvanic batteries.
718. Guitton, E. ..... Electric batteries (*Suppey*).
727. Kennedy, R. ..... Thermo-dynamo electric machines.
729. Urquhart, D. ..... Electric batteries.
734. Noad, J. ..... Galvanic batteries.
750. Lake, H. H. ..... Electric railways (*Weems*).

18th January, 1888.

789. Kingdon, J. A. ..... Distribution of electricity.
791. Scott, R. A. ..... Junction boxes for electric conductors.
804. Pulverman, M. ..... Electric clocks (*Bohmeyer*).

19th January, 1888.

873. Hen & Weinmann ..... Electric igniting apparatus.
874. Judson, F. H. ..... Electric incandescent lamps.

CHEMISTRY.

13th January, 1888.

571. Seaver, F. I. R. ..... Manures.
582. Redwood, T. H. ..... Photographing by artificial light.

14th January, 1888.

607. Rave, C. ..... Acid residuums from the refining of mineral oils.
614. Brown, J. ..... Camera dark slides.

16th January, 1888.

676. Paul, L. ..... Disulpho and dicarbo acids of the diamidoazo-benzidines.
678. Nipper, J. ..... Distemper colours.
687. Abel, C. D. ..... β-naphthylamine-λ-sulphonic acid from the so-called β-naphthylamine β-sulphonic acid (*Actiengesellschaft fur Anilinfabrikation*).
692. Clark, A. M. ..... Cobalt and nickel ores (*La Société Anonyme*).

17th January, 1888.

700. Claus, C. F. ..... Phosphates of alumina.
708. Wyley & Wyley ..... Chlorate of potash pellets.
728. Grimshaw, H. ..... Recovery of sulphur from black ash waste.

18th January, 1888.

767. Andria, M. N. d' ..... Recovering tin from tinned metal.
788. Tipping, H. ..... Production of oxygen.

19th January, 1888.

826. Kington, W. ..... Improved combination of metals.
857. Ellice-Clark & Chapman ..... Production of oxygen.
870. Crossley, A., & others.. Oxide of iron pigment.
871. Crossley, A., & others.. Evaporation of ferrous sulphate solution.

MISCELLANEOUS.

13th January, 1888.

538. Mullineux, M. ..... Cartridge cases.
539. Fletcher, J. M. ..... Spurs.
540. Needham, T. ..... Electric balloon carriages.
542. Shand, F. J. ..... Safety fuse for blasting.
544. Oxley, J. ..... Curing stinking casks.
547. Hunt, R. ..... Cotton seed oil foots.
550. Hunt, R. ..... Purification of cotton seed oil.
551. Morris & Small ..... Asbestos tipped lamp wicks.
552. Fletcher, J. H. ..... Hoods for vehicles.
553. Johnson & Boots ..... Coupling gear for railway trucks.
554. Burns, D. ..... Chimney cowls and ventilators.
558. Hornby, F. ..... Apparatus for recording numbers and fares.
559. Ivatt, H. A. ..... Apparatus for supporting windows of railway carriages.
560. Barthel & Möller ..... Projectiles.
562. Free, R. ..... Kilns for drying malt and hops.
564. Bodenham, W. ..... Indicating the strength of brine.
566. Poidevin, T. le ..... Springs for locks.
569. Hedick, W. ..... Gas and dust recorder.
570. Stains, V. D. de ..... Propulsion of carriages.
573. Pyne, R. W. ..... Adjustable horseshoe.
574. Balk, W. J. ..... Street gullies and traps.
577. Cheswright, C. ..... Capsules for the necks of bottles.
578. Moore, F. ..... Speaking tubes.
579. Walkden, S. ..... Eccentric adjustable as regards throw and angle.
583. Hughes, G. R. ..... Facilitating the composing of printing type.
588. Gries, W. ..... Buckles for straps.

14th January, 1888.

591. Sargeant, T. C. ..... Belt fastener.
593. Johnson & Green ..... Controlling the supply of steam to compound locomotive engines.
598. Jones, R. ..... Stoppering bottles.
601. Hallam, S., & others ... Valve gear.
603. Dames, C. R. ..... Preparing fuller's earth.
604. Dolman, F. H. ..... Hoof picks.
606. Nicholl, W. A. ..... Filters.
608. Stubbs, D. H. ..... Clutch.
610. Morecroft, S. ..... Metallic coffins.
613. Trench, C. ..... Kerosene lamps.
615. Tabrar, J. ..... Stoppers for bottles.
618. Fraser, W. ..... Air cushion water tap.
621. Jewell & Mark ..... Joining lead pipes.
622. Jones, A. ..... Ornamenting vitreous surfaces.
624. Chinnery & Tarbutt... Combustion of liquid hydrocarbons.
625. Moore, T. W. ..... Tricycles and bicycles.
626. Stobbs & Grant ..... Dating and numbering stamp.
628. Walker, C. M. ..... Gas lamps.
630. Andersen, W. K. ..... Valves.
631. Thorne & Burr ..... Lamps for railway purposes.
641. George & Armstrong.. Fuses for projectiles.
642. Easton & Hoyland..... Extracting juice from sugar canes.

16th January, 1888.

643. Robinson, A.S., & others. Stoppers for bottles.
644. Wetherell, F. W. ..... Rope wheels.
646. Pickard, W. ..... Metal perforated liners adapted for sewing on a covering of material.
648. Dimitry, C. P. ..... Indelible ink.
650. Crabtree, J. ..... Couplings for railway vehicles.
652. Herbert, F., & others .. Cast iron flange pipes.
658. Jackson, J. O. ..... Valves or taps.
659. Dunn, H. P. ..... Pneumatic speaking tubes.
660. Briggs, J. W. ..... Rotary pumps and engines (*Barber*).
661. Lugrin, A. ..... Repeating watches.
665. Dick, G. A. ..... Manufacture of metal stampings.
666. Bennetts, W. ..... Safety fuses.
667. Mackay, M. ..... Fusible cements.
668. Christopher, G., & ors.. Preparations of extract of tea.
671. Clay, R. ..... Lock nut.
672. Newton, H. E. ..... Life saving rafts (*Allmann*).
673. McClellan, E. S. ..... Air inlets for sewers.
675. Morgan, D. J. ..... Pistons for steam engines.
677. Quick, G. ..... Cartridges.
679. Haley, J. ..... Manufacture of glass tiles.
680. Sears & Kelley ..... Snap hooks.
683. Holzapfel, W. C. A. ... Anti-corrosive composition for steel vessels.
691. Martinson, O. ..... Apparatus for measuring and drawing off liquids.

17th January, 1888.

693. Blizzard, W. ..... Disposal of sewage.
695. Fenby, H. P. ..... Corrugated boiler flues.
696. Varley, T. ..... Propellers for ships.
697. Sisson, W. ..... Valve gear of oscillating engines.
702. Schott, G. A. J. ..... Apparatus for measuring oils and other liquids.
703. Oldfield, G. ..... Ratchet brace for giving a continuous motion to drills.
712. Brookes, J., & others.... Driving chain for bicycles, tricycles, &c.
714. Harrison, J. ..... Compensating roading used on railway points, for contraction and expansion for same.
715. Noble, J. ..... Gas producers for the generation of steam.
717. Jardine, J. W. ..... Railway fog signalling.
723. West, J. ..... Charging and drawing gas retorts.
724. Higham, A. ..... Marking strip for the use of boiler makers.
733. Sanderson, J. ..... Channel bar for ships' keels.
735. Melhuish, R. ..... Tool cabinet and bench.
736. Worssam, C. S. ..... Cutter block for wood planing.
737. Schoop, E. ..... A new agglomerated fuel (*Jouannique & Co.*)
738. Smart, H. R. ..... Ventilating apparatus.
739. Suart & Hanwell ..... Roofing tiles.
740. Grosjean, J. E. ..... Roofs.
741. Gear, H. G. ..... Improvement in wood laths (*The Coleman Grooved Lath Syndicate*).
742. Groth, L. A. ..... Tanning hides and skins by the aid of electricity.
744. Wright, R. ..... Posts, and securing them to the ground.
746. Perkins, A. B. ..... Pulleys and drums.
752. White, T. R. ..... Heating railway carriages.
754. Hawley, C. P. ..... Fastening devices for packages.
760. Smith, W. H., & others Fire lighter.

18th January, 1888.

761. Rayner, T. J. ..... Refrigerators.
762. Birley, W. ..... Railway signalling.
765. Gyde, E. L. ..... Night clock.
770. Woodhead, T. ..... Bolts, rivets, and screws.
771. McDonald, T. ..... Manufacture of cake from oil seeds.
772. Comings, W. R. ..... Dies for cutting and forming sheet brass.
778. Metcalfe, G. F. ..... Printing frame.

Digitized by Google

779. Jutson & Poupard..... Shoes for horses.
784. Dutton, T. ..... Automatic sprinklers.
785. Hurst, S. ..... Automatic lock.
786. Buckland, F. ..... Portable conservatories.
796. Reade & Shaw..... Bottles.
801. Smith & Smith ..... Twist lace fabrics.
802. Winfield, F..... Ventilating sewers.
803. Nicholls, A..... Balance rifle and gun sights.
808. Hinks, J. ..... Extinguisher mechanism for lamps.
809. Tonks & Burn..... Latches.
810. Chatwin, J. ..... Screw spanners.
815. Defries, H. ..... Ships' signal lamps.
821. Rose, J. H. ..... Railway signalling apparatus.
822. Haddan, H. J. ..... Power storing brakes (*Reimer, Reimer, & Koenecke*).

19th January, 1888.

825. Hudson, S. ..... Taps.
829. Wylde, A..... Fire escape.
830. Peyton, W. ..... Automatic tilter for beer.
833. Newcombe, H. J..... Abatement of smoke.
837. Hibbert, F. ..... Railway signals.
838. Sayer, R. C..... Filtering and storing rain water.
839. Robertson, A. W. ..... Hinges of furnace doors.
841. Lind, J..... Tubular lanterns.
842. Dale, T..... Feed valves for steam boilers.
845. Samuel, S. I. ..... Velocipedes.
847. Restall, G. F..... Disinfectant for drains.
850. Tulley, J. S..... A wheel guard.
852. Reed & Kennedy..... Manufacture of fenders.
853. Thuron & Renard..... Apparatus for transmitting motion.
855. Fox, W..... Guards for revolving shafts.
860. Conacher & Williams Production of ice.
861. Joice, J..... Carriages.
862. Leeman, E. G..... Automatic extinguishers for lamps.
866. Lingley, G. ..... Permanent way of tramways.
875. Gledhill, M. ..... Projectiles.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

21st January, 1888.

613. Boult, A. J. ..... Boring and tapping mains (*Clausolles*).
1013. Yeadon & Middleton. Apparatus for the manufacture of artificial fuel.
1270. Lake, H. H. ..... Pulverisation of mineral substances (*Raymond & Raymond*).
1784. Griffin, J. ..... Saw sharpening and saw setting apparatus.
2838. Rose, A. T. F. ..... Machinery for turning oval shaped discs.
2920. Rylands & Potter..... Regenerative gas furnaces.
3439. Campbell, C..... Washing machine.
3692. Smith, P. ..... Trap levers of twisting frames.
3820. Laing, W. R..... Frames for spinning flax, hemp, cotton, worsted, &c.
3836. Heggan, J..... Sewing machinery.
3879. Benson, G..... Machinery for slotting.
3885. Jepson, H..... Machinery for hardening felt hats.
3934. Griffin, S. ..... Gas motor engines.
3954. Rowley, J..... Canal locks.
3957. Hart, W. F. ..... Sewing machines (*Larrabee and Fischer*).
4004. Haworth & Mason..... Water heaters for steam boilers.
4006. McCorkindale, D. ..... Preparing malleable iron for making tubes.
4025. Anderson & Pollock... Sewing machines.
4115. Rogerson & Downie... Rapid-firing guns.
4140. Gover, H. C..... Apparatus for stamping.
4172. Roberts, R. R..... Machinery for opening and spreading the twist in fabrics.
4191. Lysaght, J., & others... Rolling thin gauges of iron and steel sheets.
4197. Milne, W. L..... Boilers.
4476. Lloyd, S. ..... Appliances for transferring boats from one level to another on canals.
4591. Brook & Vickerman ... Sizing, drying, and warping machines.
4601. Marshall, R. ..... Steam boiler furnaces.
4641. Holderness, W. ..... Improved ship.
4806. Halliwell, J..... Manufacture of laces.
4889. Tomlinson, T..... Apparatus for cutting sugar cane
6911. Beaudry, A..... Punching and shearing metals.
11142. Lake, H. H. ..... Casting of metal ingots or bars (*Atha*).
11455. Cooper, G. P. ..... Reaping machines.
12900. Morris, T. E. ..... Slate working machinery.
13059. Tongue, J. G. ..... Machine for cleaning leaves containing fibre (*Hemphill Fibre Machine Co.*).
15239-40-42-43-44. Cochrane, W. F..... Roller mills.
16497. Thwaite & Noble ..... Manufacture of steel.
16738. Gibbs & Olson..... Manufacture of horseshoe nails.
16745. Noble & Thwaite ..... Ingot and crucible heating arrangement.
16983. Lake, H. H. ..... Turning lathes (*Hoopes*).
17142. Jensen, P..... Nail punches (*Cowl*).
17159. Johnson, J. Y..... Machines for planing metal (*Sellers & Bancroft*).
17211. Schmidt & Spiegel..... Machine for distributing fertilisers.
17289. Tomlinson, T. ..... Apparatus for cutting sugar cane.
17295. Wilcock & Pearson ... Roving machines.
17414. Lake, H. H. ..... Machines for attaching buttons to leather (*Saunders*).
17451. Ridgway, W. H. ..... Cranes.
17486. Boult, A. J. ..... Manufacture of water proof fabrics (*Sinsabaugh*).
17531. Schott, J. C..... Button making machines.

ELECTRICITY.

21st January, 1888.

563. Leigh, H. H..... Dynamo-electric machine (*Clerc*).
701. Ferranti, S. Z. de ..... Electrical meters.
702. Ferranti, S. Z. de ..... Dynamo-electrical machines.
717. Sayers, W. B. ..... Disc dynamo-electric machines.
800. Willis, J. B..... Telegraph apparatus.
831. Immisch, M. ..... Converting alternating currents into continuous ones.
2390. Liepmann, H. ..... Electrolytical treatment of ores.
2959. Chocqueel, H. C..... Automatic switch for electric alarms.
3605. Selden, C..... Simultaneous telegraphy and telephony.
3878. Boardman, H. ..... Electric alarm clocks.
3943. Douglas, W. H..... Measuring electric currents.
4138. Cockburn, A. C. ..... Safety devices in electric circuits.
4153. Churton, T. H. ..... Mechanical telephone.
8329. Langdon, W. E. ..... Electrical signalling apparatus for railways.
11923. Menges, C. L. R. E..... Electrodes for batteries. (Received 2nd September, 1887. Ante-dated 19th February, 1887, under International Convention).
14768. Dorman & Smith..... Electric switches.
16376. Noble & Noble ..... Electric arc lamps.
17157. Lake, H. H. ..... Batteries (*Whitten*).

CHEMISTRY.

21st January, 1888.

9948. Watson, T. P. ..... Photographic cameras.

MISCELLANEOUS.

21st January, 1888.

14899. Gare, T. ..... Apparatus for copying designs.
497. Warner, A., & others... Registering mechanism.
951. Enright, J. ..... Regulating the supply of gas.
1515. Schlichter, H. ..... Lighting by means of gas.
1843. Kirk, A. C. ..... Supply of distilled water for marine boilers.
1955. Mathey, A. ..... Alarm communication for railway trains.
2043. Stickings, G. F. ..... Coupling railway rolling stock.
2252. Stevens, T. G. ..... Brake for railway trains.
2379. Crastin, C. ..... Gas burners.
2418. Moorwood, H. S. ..... Fire grates.
2484. Thornton & Walker. Straightening steel wire.
2517. Wilson, D. ..... Telegraph poles, &c.
2727. Roberts, S., & others... "Foundations" of cards for carding fibres.
3012. Keeling, T. ..... Permanent ways of railways.
3301. Lockerbie, T. ..... Pipes for conducting acids, alkalies, &c.
3387. Mills, G. E., & others... Discharge pipe, &c., of street gullies.
3475. Augé, E. J. B. ..... Chains for transmitting motion.
3532. Leynen-Hougarets, J. A. H..... Lamps.
3580. Comrie, J. S..... Torpedo indicating light gear.
3849. Meyer, B..... Preventing the explosion of steam boilers.
3859. Lovibond, J. W. ..... Apparatus for estimating the colour of liquid bodies.
3860. Golding, H..... Treating leather.
3861. Betjemann, S. ..... Appliance for attaching and releasing objects when held at a tension.
3901. Hickey, M. ..... Machines for cleaning bottles.
3909. Collier, J. L. ..... Machine for splitting almonds.
3912. Bourne, J. J. ..... Locks.
3940. Defries, H. ..... Railway lamps.
3942. Bayliss, A. A. ..... Lock bolt.
3982. Tandy & Tandy ..... Velocipedes.
4034. Killey, J. G..... Pipes of earthenware.
4040. Shaw, G. H..... Guard for drums employed in thrashing machines.
4065. Prosser, J..... Extinguishing oil lamps.
4066. Davy & Benton ..... Valve gear of steam hammers.
4079. Enright, J..... Burglar alarms.
4089. Attree, G. F. ..... Fog signalling apparatus.
4095. Phillips, R. E..... Velocipedes (*Overman*).
4119-20. Spencer, A. ..... Chains for sprocket wheels.
4160. Beechey, C. G..... Gas bags for gas engines.
4203. Kerfoot, T..... Dry saccharated extract of tea.
4246. Reed, J. W. ..... Apparatus for cutting button holes.
4295. Maynes, J. ..... Manufacture of fire lighters.
4487. Lindsay, W. H..... Utilisation of cinder waste.
4541. Dutton & Cay..... Railway lamps.
4704. Noble, A..... Gas checks for the joints of jointed guns.
5464. Bertling, L. ..... Lithographic process.
5962. Holland, H. W. ..... Counter for guns for recording the number killed.
6893. Downie, T. ..... Copying presses.
9097. Stone, L. W..... Creasing cardboard.
14023. Willway & Moon ..... Apparatus for regulating temperature.
15364. Mason, D..... Treating wool (*Schlamm and Brassard*).
16372. Sayer, R. C..... Filtering and storing rain water.
17029. Vanzini, J. M..... Lubricators.
17239. Taylor, W. ..... Locking device for the covers of rotating shafts (*Lejeune*).
17328. Schubert, J..... Locks.
17342. Finch, W..... Fumigating apparatus.
17452. Kennedy, De L. ..... Projectile.
17458. Horne & Hollyman ... Chimney top to induce up draught.
17467. Bosch & Kumpfmiller. Sheets of metal combined with rubber or analogous gum.
17483. Boult, A. J. ..... Concrete pavements (*Barber*).

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(To the 14th October, 1887, inclusive.)

Year 1883.

4766. Jameson, J. ..... Coke ovens.
4767. Twigg, G..... Cap for teeth of horse clippers.
4772. Davison, J. S. ..... Stoppers for bottles.
4773. Robbins, E. ..... Cements, &c.
4776. Bartlett, W. A. ..... Controlling gases for motors (*Haight & others*).
4779. King, J. T. ..... Metallurgical furnaces (*Bissell*).
4791. Kenyon, J. ..... Permanent ways of railways.
4793. Justice, P. M. ..... Railway signal systems (*Cutala*).
4795. Clark, A. M..... Fire escapes (*Zerr*).
4796. Clark, A. M. ..... Bottle washing (*Cowles*).
4797. Potter, C. W. ..... Compressors and engines.
4800. Johnson, J. H..... Electromagnets (*Recordon*).
4802. Haddan, H. J. ..... Velocipedes (*Overman*).
4804. Haddan, H. J. ..... Nails (*Tenney*).
4805. Lake, W. R. ..... Bearings for journals, &c. (*Traylor*).
4809. Dey, D. P., & another... Hydraulic steering.
4814. Richardson, J., & ano.. Picking motion for looms.
4816. Williamson, T. M. & ors. Gas motor engines.
4817. Sibree, J. T., & another Propelling velocipedes.
4819. McHardy, J..... Sewing machines.
4821. Glaser, F. C. ..... Railway brakes (*Bolzano*).
4823. Wesselmann, B. ..... Snap hooks.
4835. Bonson, M. ..... Magneto generators (*Stabler*).
4838. Kerfoot, J..... Piston rings.
4839. Sturge, E. ..... Generating motive power.
4844. Gedge, W. E. ..... Purifying lighting gas (*Secrel*).
4851. Price, A. P..... Extraction of precious metals from their ores.
4852. Davis, T. ..... Compressing, &c., packets of substances.
4853. Pieper, C. ..... Solidifying liquid acids (*Vorster and another*).
4854. Sackur, H. ..... Grinding machine.
4856. Redfern, G. F. ..... Gas (*Giraudon*).
4863. Vallet, L. ..... Internal stoppers for bottles.
4865. Muir, A. ..... Coupling shafting.
4871. Simon, H., & another... Ammonia.
4876. Briggs, J..... Kilns.
4878. Jacobsen, C. ..... Steam engines.
4880. Anders, G. L. ..... Telephonic apparatus.
4884. Wrild, E..... Ticketing bobbins.
4885. Benton, C. H. ..... Dynamo-electric machines.
4888. Greig, A..... Street sweeping.
4891. Kinder, W. J..... Spinning, &c., textile materials.
4894. Williams, S. de la G... Kilns.

Year 1882.

4803. Britain, W. ..... Bicycles.
4806. Hornsby, J., & others... Harvesting machines.
4814. Motherwell, W. ..... Moulder's nails.
4817. Dowrie, T. ..... Transparent block ice.
4854. Wise, W. L. ..... Transmitting heat to fluids (*Röber*).

Year 1881.

4410. Morgan-Brown, W. ... Planing wooden hoops (*Campbell*).
4452. Wise, W. L. ..... Frictional couplings (*Mégy and another*).
4455. Swan, J. W. ..... Secondary batteries.
4474. Wise, W. L. ..... Motors (*Mégy*).

Year 1880.

4094. Elmore, W. ..... Extracting copper from its ores.
4097. Webb, H. C..... Producing coloured patterns.
4098. Dick, G. A. ..... Furnaces.
4116. Lake, W. R. ..... Transmitting electrical currents (*Maiche*).
4125. Mathewson, J., & ano... Coal plates.
4175. Gallie, S..... Bolt making.
4185. Marshall, F. C. ..... Valve gearing.

Year 1879.

4080. Lindsay, R. B. ..... Ashes lifters.
4117. Alexander, J., & ano... Utilising gases of blast furnaces.
4141. Clark, A. M. ..... Steel (*Launay*).

Year 1878.

3966. Wilson, J. W. ..... Bobbins, &c.

Year 1877.

3722. Rodger, G. ..... Producing vacuum in condensers, &c.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

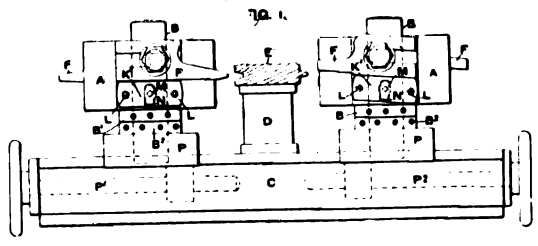
Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Hydraulic Riveting.—*H. T. Shaw & C. Chittick, London.*—The object of this invention is to provide machinery by which hydraulic punches can be shifted readily whilst forming holes in girders, &c. The work to be riveted is erected between gantries set at a distance apart. A traveller resting on rails at the top of the gantries bridges over the space between them. This traveller carries the tools, and also has a roof suspended from it, under which the men can work in any weather. The traveller consists of girders crossed with purlins, on which is carried a corrugated iron roof. A beam extends transversely to the girders, and is suspended from wheels which run on the bottom flanges of the girders. This beam carries the riveting tools, which can thus be moved from place to place. The inventor claims the combination of traveller and gantries for the purpose described.—No. 2743. February 22nd, 1887. 8*d.*

Mowing Machines.—*S. S. Bromhead, London.* (*G. A. Weaver, Newport, U.S.A.*)—The object of this invention is to provide means for adjusting the pivots of the rollers placed between the finger bar and the sliding cutter bar. The rollers are journalled in blocks, which are provided with slots diagonal to the direction in which the block is moved during adjustment. Bolts or screws pass through the blocks and finger bar, and secure them in position. The adjustable blocks are provided with an extension, which projects over the knife bar, and prevents it springing from its seat. Five claims are made for the improvements described.—No. 15349. November 10th, 1887. 6*d.*

Planing and Chipping Machines.—*S. Bastow, Leeds.*—This invention introduces certain improvements for facilitating the correct setting and adjustment of the knives and cutters of moulding, planing, and chipping machines. Fig. 1 represents a front elevation, and Fig. 2 a plan of the improved cutter heads. A are the loose heads, which may be either square or hexagonal, and the cutter blocks are placed upon spindles B, which are adjustable by means of the screws P^1 and P^2. The bed D holds the board which is required to be operated on, and the lock



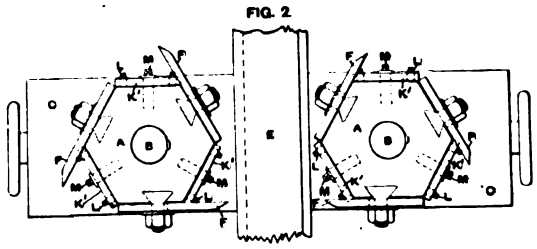


FIG. 2

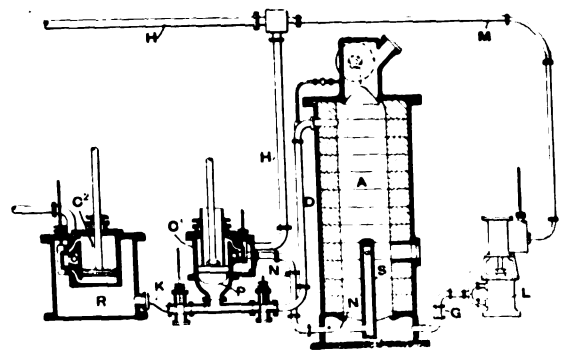
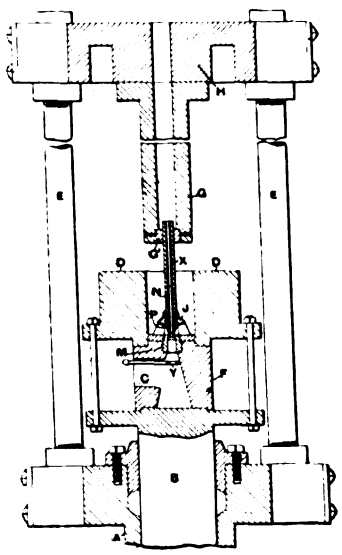


nuts B^1 B^2 allow the spindles B to be raised or lowered. For the adjustment of the knives a pivoted plate K^1 is employed, which is provided with screws L; a centre pin M with a square neck is tapped into the cutter block, and radiates to any angle in the slot N of the pivoted plate. By slackening the screws L the plate can be made to move on its pivot, and to slide up and down on the square of the pivot. The plate may be again secured by tightening the screws L, and the knives bearing against the plate can be taken off and put on without disturbing the angle of the plate. There are two claims made.—No. 6913. May 11th, 1887. 8*d.*

Calcining Furnaces.—*F. M. Spence & D. D. Spence, Manchester.*—This invention relates to furnaces for heating, drying, and calcining mineral substances, and has for its object the performance of the usual operations with greater efficiency and economy. An annular rotating dry-luted furnace is employed, having fixed sides and roof. Across the bed of the furnace are placed two vertical diaphragms at such a distance from each other as to allow between them the feeding apparatus and discharge plate. The bottoms of the diaphragms extend to the surface of the layer of material on the bed of the furnace. The heating gaseous medium enters through apertures on one side of the diaphragm, and passes through and leaves the furnace on the other side. A number of flues are arranged over the annular bed for the purpose of leading away the waste gases from the bed. The material is placed on the floor forming the covering of the flues before being put on the annular bed, and is thence fed continuously to the revolving floor of the furnace. The apparatus used in feeding the material consists of a plate on the right of the left hand diaphragm and at a short distance from it, the space between the plate and the diaphragm thus forming a hopper, which is supplied continuously with the material. To secure the proper confinement of the gaseous medium, a roof is provided; and through the side wall of the furnace are apertures through which the workmen can inspect the progress of the operation. The inventor makes four claims for the combinations.—No. 2119. February 10th, 1887. 8*d.*

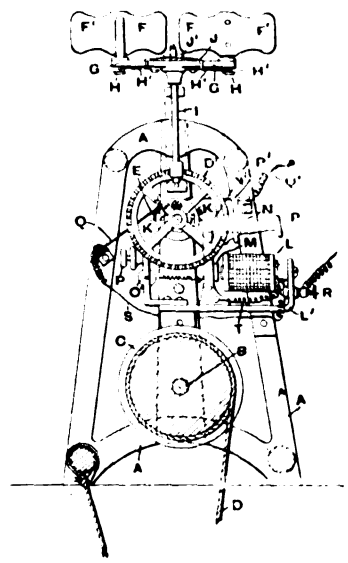


Cold Drawing Machines.—*E. Sandkuhl, London.*—This invention relates to machines for cold drawing and compressing metal bars, rods, tubes, and wires, and to hydraulic apparatus for actuating the same. The die is made with its exterior surface slightly coned, and the internal surface of the die holder is made to correspond therewith. As a better support is given, a lighter die may be used than is usual. The grippers in the cross head are also provided with conical surfaces. The die holder is placed on a spherical seat in the head of the drawing machine so as to form a universal joint. The slide valve of the hydraulic mechanism is provided with a lever, which is drawn over and allows the water to enter the cylinder. Upon the completion of the stroke, the lever is operated by any part of the mechanism, and the machine is stopped. The inventor makes five claims for the improvements described.—No. 13506. October 5th, 1887. 8*d.*

Steam Engines.—*M. P. W. Boulton, Tew Park, Oxford, and E. Perrett, London.*—In this engine the chief agent employed is steam, but a certain quantity of hot gases resulting from combustion are at some stage of operations introduced into the apparatus, and mixed with the steam. The principal service of these gases is to superheat the steam, but they also assist the steam in the performance of work by their own expansion. One of the forms of apparatus designed according to this method is shown in diagrammatic manner in the annexed figure. A steam boiler of ordinary construction supplies the high pressure steam

through the pipe H. The steam passes through the valve case at the upper end of the cylinder C^1, and acts on the annular area on the upper side of the differential piston P^1. The exhaust steam passes by the pipe N to the combustion chamber A, in which the steam mixes with the products of the combustion therein maintained. This mixing causes the steam to be superheated, and the resulting mixture of gas and steam is led by the pipe D to the lower end of the cylinder C^1, and there acts on the full area of the under side of the piston P^1. The exhaust from the lower end of the cylinder C^1 passes by the pipe K to a reservoir R, from which both the ends of the low pressure cylinder C^2 are supplied. The superheater A is supplied with the air required for the combustion of the liquid fuel by a pipe G from an air compressing pump L, which may be worked as shown by an engine supplied with steam from the boiler by the pipe M. In another form of this invention the superheating chamber is constructed for the combustion of solid fuel. The vessel is lined with refractory material, and has in the middle of its height a grate, on which such fuel as coke or charcoal is placed. At the higher end of the vessel is a valve, like those which are used for feeding fuel to hot air engines, and the pressure on this valve is balanced, when it has to be opened, by admitting steam above it. Air for the support of combustion is forced in underneath the fire, and steam from the boiler is introduced above the fire in quantity regulated by a valve. The inventors make five claims.—No. 459. January 11th, 1887. 11*d.*

Apparatus for Covering Electrical Conductors with Lead.—*R. W. Eddison, Leeds.*—The diagram represents a transverse section of the press, and shows the improvements introduced. The invention refers to machines of the type described in Tatham's Patent No. 11879 of 1885, and has for its object the



prevention of injury to the insulated covering of the conductor whilst it is being covered with hot lead. A is part of the hydraulic cylinder of a lead pipe press, and B is part of the plunger which carries the lead reservoir D. The interposed column F contains a lateral passage C, and the upper fixed ram G is bolted to the cap H, which is secured to the cylinder by means of the pillars E. The block J has a central chamber and opposite lateral passages; and into a threaded opening in the bottom of the block is screwed the die M, the projecting portion of which is contained in a recess in the column F. A threaded opening in the top of J admits the hollow core N, the upper end of which fits in a block G^1 in the lower end of the ram G. The core N has a detachable end P, which is held in position by a set screw. The insulated wire is drawn through the cap H, the ram G, the hollow core N, and out through the lateral opening C. The core and its projection are lined with asbestos as at X, in order to protect the insulating material from the injurious effect of the heat of the core; and an internal shoulder is formed in the tube close to the nose to keep the lining in its place. A perforated pipe Y is placed beneath the die so as to throw jets of water on to the covering of the insulated conductor directly it issues from the die. The inventor makes four claims for the combinations of reservoir, ram, and die, with the hollow core and its shoulder.—No. 15329. November 9th, 1887. 8*d.*

Compound Steam Engines.—*R. R. Bevis, Birkenhead, and J. D. Churchill, London.*—This invention is designed for the object of more perfectly controlling and governing multiple expansion engines. A double beat throttle valve is placed in the pipe which conducts the exhaust steam from the high pressure cylinder to the expansion chamber of the second cylinder. The same governor is made to operate this valve simultaneously with the usual valve in the steam supply pipe. The result of this arrangement is to cut off the supply of steam to both cylinders, and to cause the exhaust steam from the first cylinder to exert a back pressure. This extra throttle valve is connected to the governor by a gear, which, however, allows the valve to open temporarily when the pressure against it exceeds a certain limit. This locking gear is enclosed in a pipe which is carried in suitable brackets. The inventor makes five claims for the placing of the throttle valves and the details of the locking gear for the object described.—No. 2432. February 16th, 1887. 8*d.*

ELECTRICITY.

Electric Unison Motors.—*A. J. Boult, London.* (*J. F. McLaughlin, Philadelphia.*)—These instruments are designed for the purpose of synchronously revolving two or more separated shafts, one of them being placed at each end at the extremities of a line circuit. In the accompanying diagram, which represents a vertical sectional view, are shown the essential features

of the instrument. A train of wheels, comprising a clock movement, is operated by a weight attached to the cord D, which is wound on the drum C. The governor wheel D^1 transmits motion to the governor F, and also to a vertical shaft, by means of bevel wheels, which are not shown in the drawing. The revolution of this vertical shaft is controlled by the devices which are the subject of this invention. The governor F consists of two adjustable wings F^1, vertically pivoted in the adjustable cross bar G. Two curved springs H^1 are secured each to the under side of the cross bar G, and at their bifurcated extremities press down upon the bolts H, so that their tension will exert sufficient pressure on the pivot pins to prevent the resistance of the air from displacing the set position of the wings. A spring friction clutch J is secured to the shaft I by a pin J^1, and bears equally on either side of the cross bar, thereby preventing the cross bar from being dislodged by the revolution of the wings. The contact wheel E is fixed to the same shaft as the governor wheel D^1 by a pin K, which passes through an insulated traverse aperture. This contact wheel is insulated by a sleeve of hard rubber from its shaft, and upon its periphery is embedded a platinum contact pin K^1. The electromagnet L, provided with a yoke piece, is supported by the bracket L^1, and the armature M is fastened to the lever N, and is provided with a platinum point N^1 to engage with the pin on the contact wheel. O is a retracting spring fastened as shown, and P P are adjustable screws to limit the play of the lever N. P^1 and Q are two metallic contact brushes which are fixed to and insulated from the frame work, and they bear respectively at their inner free ends upon the contact wheel E. The brush P^1 is in circuit with a battery by the wire Q^1, and the brush Q is in circuit with the line and electromagnet L through the binding posts R and the wire S. The inventor makes nine claims for these improvements.—No. 11200. August 16th, 1887. 8*d.*

Electric Furnace.—*S. Z. de Ferranti, London.*—According to this invention, the current which circulates in the crucible is not conducted there from the outside, but is to be induced in it by a varying magnetic field. In one form of apparatus designed according to this principle, the crucible is of an oblong annular shape, and magnet core pieces rise up through the open space in the centre and outside each of the two longer flattened sides of the crucible, and an insulated conductor is wound between the pole pieces below the crucible. The

Digitized by Google

central and outer pole pieces are connected at the bottom so as to form two horseshoe magnets embracing the two longer sides of the crucible respectively. Removable connecting pieces are also placed over the tops of the pole pieces. The crucible forms a continuous trough open at the top, and a suitable lid is provided by which it can be covered over when the surface is in operation, while the whole furnace may be mounted on trunnions. In another form of the furnace, a coil of insulated conductor is placed above the crucible as well as below it, and the pole pieces by which each side of the crucible is surrounded are formed from concentric rings of sheet iron, each formed of a bent iron sheet. The inventor claims an electric furnace in which the material is heated by currents induced directly in it. —No. 700. January 15th, 1887. 8*d*.

ELECTROLYSING BLEACHING SOLUTION.—*E. Hermite, E. J. Paterson, & C. F. Cooper, Dalston, London.*—This invention relates to the construction of the electrolysing apparatus and connected with the method of bleaching described in Patent No. 13929 of 1884. The material to be bleached is acted on by a solution of magnesium chloride which is subjected to electrolytic action. In communication with the bleaching vessel is placed another vessel, through which the bleaching liquor is caused to circulate in contact with the electrodes. The improved electrolysing apparatus is shown in elevation and plan in Figs. 1 and 2. The object of the improvement is to increase the surface exposed

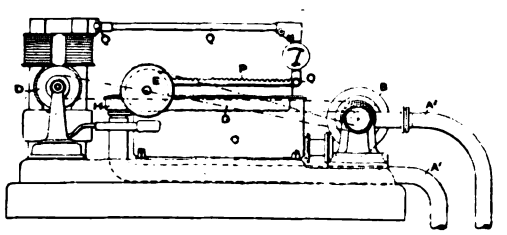


FIG. 1.

to the liquid, and to render the apparatus accessible for repair. The rotary pump B draws the liquor from the tank A and discharges it into the electrolysing cell C, while the pipe A^1 allows the electrolysed liquor to flow back to the tank A. The dynamo D, the shaft E, and the rotary pump B are all driven by belt gearing from one motive shaft. The liquor enters C through a perforated pipe which lies at the bottom of the cell; and after rising between the negative and positive elements overflows into side channels G and end channels H, and thence to the descending pipe A^1. The cell C is partly divided by a longitudinal partition, and in each of the compartments so made are journalled the shafts K, which are caused to revolve by worm

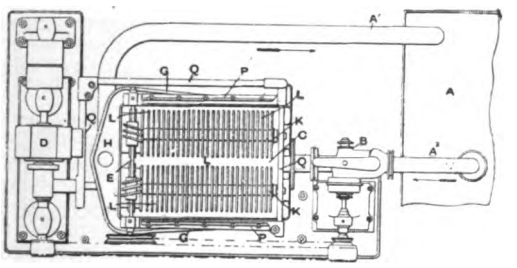

FIG. 2.

gearing on the shaft E. Zinc discs L are fixed to these shafts, and between each pair of discs is placed a platinum plate. Each of the platinum plates is held in a frame, from one corner of which projects an arm carrying a bolt. These bolts are all held in the notches of the rack P, which is insulated from the cell and connected with one pole of the dynamo by the rods Q. The other terminal of the dynamo is connected directly to the metal of the cell C. On the partition, which partly divides the cell, the inventors place inclined scrapers, which scrape the discs L and the shaft K as they revolve. There are five claims for this improved apparatus, together with certain alternative modifications.—No. 1993. February 8th, 1887. 11*d*.

CHEMISTRY.

CYANOGEN COMPOUNDS FROM COAL GAS.—*O. Knublauch, Cologne.* —In the improved process the gas mixtures are passed through a liquid containing alkaline earths and oxides or hydrates of iron suspended in it. The cyanogen is thus brought into closer contact with the iron and alkali, and the resulting ferrocyanogen salt, being immediately dissolved on its formation, does not form an obstruction to the further combination of the iron, alkali, and cyanogen. If there is any sulphuretted hydrogen in the gases, the prussic acid combines with it, and thus the amount of ferrous sulphide formed is small. The inventor makes two claims.—No. 15184. November 7th, 1887. 6*d*.

SULPHATE OF ALUMINA.—*J. J. Hood & A. G. Salamon, London.* —These improvements relate to the separation of the iron salts from crude sulphate of alumina. The ferrous salt is first oxidised and brought into the ferric state by adding a certain quantity of potassium chlorate to the solution. The precipitation of the iron is then effected by the gradual addition of sodium tungstate. The inventor makes two claims.—No. 2966. February 25th, 1887. 4*d*.

PURIFICATION OF ALCOHOL.—*T. G. Bowick, Harpenden, Hertfordshire.*—The essential feature of the combination of operations described in this invention is that alcohol is brought in an atomised condition into intimate contact with certain hydrocarbons, and that this mixture forms an emulsion which is separated by osmotic action. The carrying out of this process involves the use of a series of cylinders, each of which is jacketed for the circulation of warm water. The cylinders are made about 7ft. high and 2ft. in diameter, and are all filled to a height of 2ft. with pure alcohol, except the last of the series, which is completely filled. Six inches from the bottom of the cylinders are placed diaphragms of some filtering material. The upper 5ft. of the cylinders are filled with well refined hydrocarbon, preferably that known as "intermediate oil" in the refining of petroleum. A similar diaphragm is also placed 6in. from the top of each of the series of vessels which contain the hydrocarbon and the alcohol; and each of the cylinders is provided internally with a four bladed turbine or sparger, which revolves on a tubular vertical axis. The blades of the turbine are hollow, and are provided with roses at their ends, which are so placed that, when liquid is forced through the axis and through the blades and roses, the whole turbine revolves rapidly. Two series of pipes connected with a supply of hydrocarbon and alcohol respectively admit these two liquids to different ends of the vertical tubular axis of the turbine, and when pressure is exerted by pumps these liquids are forced together through the roses and become intimately mixed. The alcohol falls through the pure hydrocarbon contained in the cylinders, and the diaphragms filter it, and abstract all its hydrocarbon and impurity by osmotic action. This action takes place through the whole succession of cylinders until the alcohol arrives at the end of the series in a purified condition. The inventor makes eight claims for the process described.—No. 14737. October 29th, 1887. 8*d*.

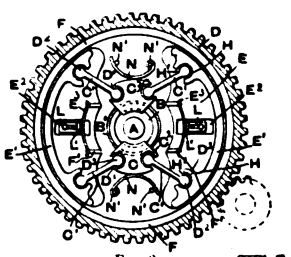
ARTIFICIAL MANURES.—*A. Campbell, London.*—This invention involves the mixing together of a phosphate of alumina or iron, such as Redonda, with low class phosphates of lime. The phosphates of alumina or iron are calcined and ground to a fine powder. By calcination the phosphates lose their water, and the percentage of phosphoric acid is thus increased and rendered soluble in citrate of ammonia. By virtue of the latter property, these phosphates are suited to mix with low class superphosphates of lime, thus furnishing manures soluble in water and citrate of ammonia, which is capable of dissolving any desired percentage of phosphoric acid. The inventor makes two claims.—No. 2459. February 17th, 1887. 6*d*.

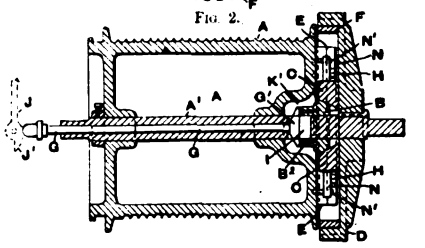
SOAP.—*S. S. Sugden, Woodford, Essex.*—The inventor takes fatty matters and treats them with oxide of lead, so as to produce the usual soap with a lead base. As soon as saponification is complete, the glycerine is removed by means of hot water, and soda lye is run upon the lead soap. By the application of heat a rapid decomposition takes place, the fatty acids relinquishing union with the lead base and combining with the soda base. The saponaceous paste floats on the surface, and the lead subsides to the bottom of the vessel. After the precipitated lead has been washed, it is mixed with oil, and can be used as a pigment; while the glycerine produced is decolourised with charcoal. The inventor makes three claims.—No. 1033. January 22nd, 1887. 6*d*.

MISCELLANEOUS.

FRICTION CLUTCH.—*I. G. Hooper, Newark, New Jersey, U.S.A.* —In the accompanying drawings the improved clutch is shown as applied to the drum of a hoisting machine. Fig. 1 represents a section through the clutch, and Fig. 2 a longitudinal section of the barrel. At one end of the drum A is a recess K^1, in which is arranged a sliding collar B. This collar has a bevelled surface B^1, which engages with a correspondingly inclined surface on the blocks C. The rods C^1 are pivotally attached to these

FIG. 1.





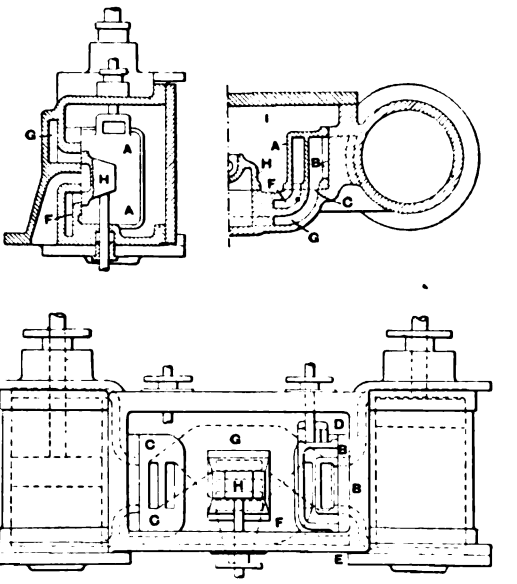


FIG. 2.

blocks C, thus forming an elbow joint. The segmental expanding plates E are provided with broadened flanges F^1 on the outside, which form frictional surfaces. When the plates are thrown outwardly, these surfaces engage with the inner peripheral surface of the gear wheel D. In the segmental plates are slots E^2, in which are arranged slotted angle plates L, secured to the recessed face of the hoisting drum. These plates serve to cause the segmental plates to turn with the drum, while permitting their necessary outward movement. The projecting part L^1 of the angle plates provides a fixed stop, against which the springs E^3 bear at their central point. The springs N, secured to the drum by pins N^1, bear against the top of the blocks C, and the rods C^1 are secured to the plates and the blocks C by forming annular recesses F^1 and C^2 therein. Springs are also arranged between the end of the driving collar and the gear wheel, and upon the release of the collar these springs force the collar backward away from the blocks, and thus co-operate with the springs E^3 and N in returning the several parts of the clutch to their normal disengaged position. The mechanism for producing the forward motion of the collar against the inclined surface of the blocks consists of a rod G arranged within the hollow shaft A^1. One end of this rod bears against a plate G^1 moving in a slot I, and the opposite end projects from the shaft and is provided with an adjustable cap. An arm and cam lever J engages the said cap when the lever is depressed, and forces the rod G forward, causing the sliding motion of the collar and its engagement with the blocks C. The inventor makes two claims for the combinations of various parts.—No. 14817. October 31st, 1887. 8*d*.

SLIDE VALVES.—*C. H. Thompson, Gateshead.*—The novelties introduced by this invention are that the steam face of the cylinder has two admission ports but no positive exhaust port, that the steam pressure is always upon the outside of the slide valve, and that the regulating valve for reversing the motion works upon a steam face which has two admission and one exhaust passages. The accompanying figures show sections of the apparatus in the three principal directions. The slide valve A slides against two surfaces B C, one at the side and one at the bottom of the valve. In the side face of the steam chest there are only two ports D E, one leading to each end of the cylinder. In the bottom face C are two ports F G, which communicate with the two passages leading to the regulating valve H. The valve A is so constructed that the fluid medium, air, steam, or water, can only enter the cylinder by means of the two pipes communicating with the valve H, although the slide valve works inside the steam chest in the ordinary way. In

the side face B of the valve an exhaust recess is made with an opening leading into it from the bottom face C, and communicating with the passage G; and the edges of the recess regulate the admission and exit of steam in the usual way. The edges on the ends of the valve A act in the same way as the steam edges of the D shaped slide valve. Thus as regards the admission and exhaust of steam directly to the cylinder, the inventor has an ordinary slide valve; but he carries round the back or top of this D valve a covered passage, and makes a port leading out of this passage through the bottom of this valve to communicate with the other passage leading to the regulating valve H. If the regulating valve H is placed so as to allow the steam to flow through the passage G to the exhaust recess of the valve, the passage F will act as an exit passage for the steam, and the exhaust edges of the valve will be turned into steam edges and *vice versa*. If the valve H be moved so that the steam is allowed to flow through the passage F to the ports or outside edges of the slide valve, the action will be immediately changed, the steam going past them in the usual manner, and the exhaust steam going through the passage G, thus allowing the steam to flow into the opposite end of the cylinder, and so reverse the engine. The inventor makes one claim for a two-faced D valve, each face being provided with two ports supplied with the motive agent through a regulating valve for determining the action of the main pistons, as described.—No. 2054. February 9th, 1887. 8*d*.

DIFFUSING APPARATUS FOR TREATING SUGAR CANE.—*H. H. Lake, London.* (*Compagnie de Fives-Lille, Paris.*)—This invention introduces improvements for operating the doors of cylindrico-conical diffusers of great capacity. The movable bottom of the diffuser constituting the discharge door is articulated at the centre of its height, and is provided with a counterweight for the purpose of balancing the door in any position. The opening of the bottom is effected by means of two rods supported in sockets which are attached to the shell of the apparatus between the hinge of the door and the axis of the diffuser. Each rod is screw threaded at its lower part, and carries a nut which slides freely in a guide fixed to the diffuser. To each nut is articulated one end of a rod, the lower extremity of which is connected to the door of the diffuser, so that when the screwed rods are turned in one or other direction, the nuts are moved upwards or downwards, the doors being consequently opened or closed. These two opening rods are connected with each other at their upper ends by a shaft and bevel wheels, and are operated by a single crank. The movable bottom when closed is secured at points diametrically opposite to the opening rods by the following means: Two locking rods, screw threaded at their lower ends, are supported in bearings upon the shell of the diffuser; and each of these screw threads carries a nut, to which are articulated two connecting rods united at their lower extremities to a link having a counterweight. These connecting rods are guided in grooves in the sides of the bearings supporting the locking rods. A small rod pivoted upon each locking rod socket has a slot in its lower part, and limits at a certain moment the vertical descending motion of the closing link, and afterwards causes it to describe an arc of a circle upon the lower axis of the small rod, and disengages this link from the catch riveted to the door. The two locking rods are connected at their upper

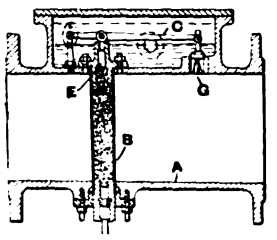
Digitized by Google

part by a shaft and gear wheels, which are actuated by a single crank. The door is thus supported at four points, and the operation of opening and closing can be performed from the top of the whole apparatus. The inventor makes three claims.—No. 2905. February 24th, 1887. 8*d*.

Apparatus for Mixing Granular Materials.—*J. Crosfield and E. Beck, Warrington.*—The object of this invention is to mix two or more granular or pulverulent materials in definite proportions. The materials are placed in separate hoppers, which empty themselves into the mixer. The feed apparatus consists of a feed wheel with a screw-regulated slide below it. The wheels are placed in the necks of the hoppers, and are preferably of the form of spindles with arms placed thereon. The spindles are geared together by pitch wheels and chains, which are driven from the mixer shaft, and the diameters of the pitch wheels are regulated according to the required proportions of the constituent materials. The mixer made use of is a horizontal cylinder, revolving on a central shaft, which is provided with stirrers of the form of Archimedean blades. The inventors make three claims for these combinations. —No. 2231. February 12th, 1887. 8*d*.

Adjusting Apparatus for Carding Engines.—*G. Ashworth and E. Ashworth, Manchester.*—This invention provides means for adjusting and levelling the side frames of carding engines. Instead of using wedges and other temporary apparatus, the inventors make use of a jack, which consists of a flat metal plate recessed to contain an anti-friction bowl projecting slightly above the level of the plate. The jack plate is provided at each end with set screws having thumb or other heads to facilitate their being turned. When in use the plates are put beneath the frames and between the feet, the conical ends of the set screws bearing upon smaller counter-sunk plates laid directly upon the floor. By turning the screws the frame may be raised entirely from the floor, and as it then rests on anti-friction bowls it may be easily moved in either direction and adjusted longitudinally or perpendicularly. In a modification of this invention the set screws are employed to slide wedges which raise or lower the frame, and cams also may be used to serve the same purpose. The inventors make three claims.—No. 1762. February 4th, 1887. 8*d*.

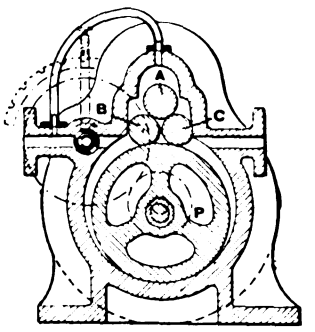
Lubricators.—*H. Bamford, London.*—These lubricators are more particularly applicable to gas engines, but may be used for other purposes. A glass vessel or reservoir contains the oil, and from its lowest part a pipe communicates with the cistern of the lubricator. The orifice at the lower end of the pipe must be in such a position that the oil covers it when at the desired level, thus preventing the return of air up the pipe when the surface of the oil is lowered. No air can enter the lubricator except through this pipe. For the purposes of filling, the upper part of the reservoir is perforated with an opening, which is made air tight by a valve on the inside of the case. A spiral spring keeps the valve in its seating. This valve is attached to a spindle, which projects downwards and carries another valve, for the purpose of opening and closing the orifice in the upper end of the pipe communicating with the lubricator. The spindle is also carried through the opening in the upper side of the reservoir, and terminates in a button which can be pressed down by hand. The position of these valves on the spindle is such that when the upper valve is opened for filling by pressing down the button, the lower valve closes the orifice in the upper end of the pipe, and prevents the oil escaping into the lubricator. When the pressure on the button is removed the upper valve is returned to its seating by the spiral spring, which at the same time lifts the lower valve and establishes the communication with the lubricator. The inventor claims the arrangement of parts for the purpose described.—No. 2236. February 12th, 1887. 8*d*.



Manufacture of Explosives.—*H. S. Maxim, London.*—The object of this invention is to diminish the liability to accidental explosion of dynamite, blasting gelatine, &c. One source of such danger is that dynamite and blasting gelatine contain a large proportion of air between their particles, and when a sudden impact is imparted to the compound, the compression of this air generates sufficient heat to cause an explosion. In order to eliminate the air from dynamite, the inventor places it in a vacuum, and then compresses it into a solid inelastic mass; or by filling the interstices between the grains with water, drives out the air hitherto located there. The apparatus used consists of a cylinder provided at one end with numerous perforations; a piston works in the cylinder, whose perforated end is connected with a chamber in communication with an air pump. The explosive material is placed in the cylinder between the piston and the perforated end, and is forced through the holes in fine threads into the vacuous chamber, where it is completely exhausted of air, and while in that condition is compressed into blocks. To eliminate air from blasting gelatine, the material is placed under water or in a vacuum, and is there subjected to the action of rotating and stationary knives or other suitable mixing and kneading apparatus. The inventor claims: (1) The method of decreasing the danger of explosives by eliminating the air therefrom; and (2) the apparatus for pressing the material through the fine holes into a vacuous chamber for the above purpose.—No. 2628. February 19th, 1887. 8*d*.

Agitators.—*W. Creswick, Wakefield.*—The improved apparatus is employed for turning over, agitating, and propelling forward substances in a powdered, broken up, or semi-liquid state, over floors the temperatures of which are raised or lowered according as the substances are to be heated, dried, or cooled. Endless bands or chains are passed round pulleys or drums mounted at the ends of the floor, and carry sets of ploughs or scrapers which act upon the material spread over the floor and gradually move it from one end to the other, at the same time turning it over. Two claims are made for the improvements described.—No. 15590. November 14th, 1887. 6*d*.

Manufacture of Ropes.—*G. H. Hebblethwaite, Huddersfield.*—The inventor proposes to construct ropes for the transmission of power by rope and pulley gearing, without twisting or folding the strands. Either cotton, flax, worsted, or hemp may be employed, and the fibres are so woven as to form a solid belt or strip of a certain width. Several widths required to form a sectional rope of V form are secured together by means of rivets or wire stitching, in order to fit the V groove in the rim of the pulleys. The top and bottom layers may be made of leather. The inventor claims the manufacture of ropes as described.—No. 2592. February 19th, 1887. 4*d*.



GERMAN PATENT ABSTRACTS.

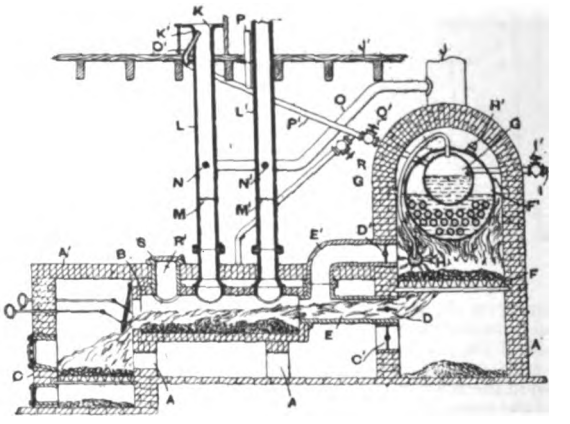
Superheating of Steam.—*Max Gehre, Düsseldorf.*—This invention relates to an apparatus for regulating the superheating of steam. A tube B is inserted into the steam pipe A and filled with quicksilver. The end of B is closed by a piston E, which actuates a lever C, carrying on one end a valve G. As soon as

the temperature in A exceeds a certain limit, the quicksilver expands and lifts the piston E, thereby raising the lever C and opening the valve G, which admits water into A until the temperature has again become normal.—No. 41473. May 4th, 1887.

Rotary Pump.—*L. Neut & Co., Paris.*—A drum P is attached in such a manner as to move freely round the crank of the shaft fixed in the centre of the circular casing shown in section in our illustration. This shaft is actuated by two toothed wheels. The rollers A B C are pressed against P and the inside

of the casing by the water flowing through the small pipe connecting the suction pipe with the upper part of the casing. The rollers A B C take the place of a valve, and prevent the water from running back. The supply is cut off by a valve in the suction pipe.—No. 41438. January 22nd, 1887.

UNITED STATES PATENT ABSTRACTS.



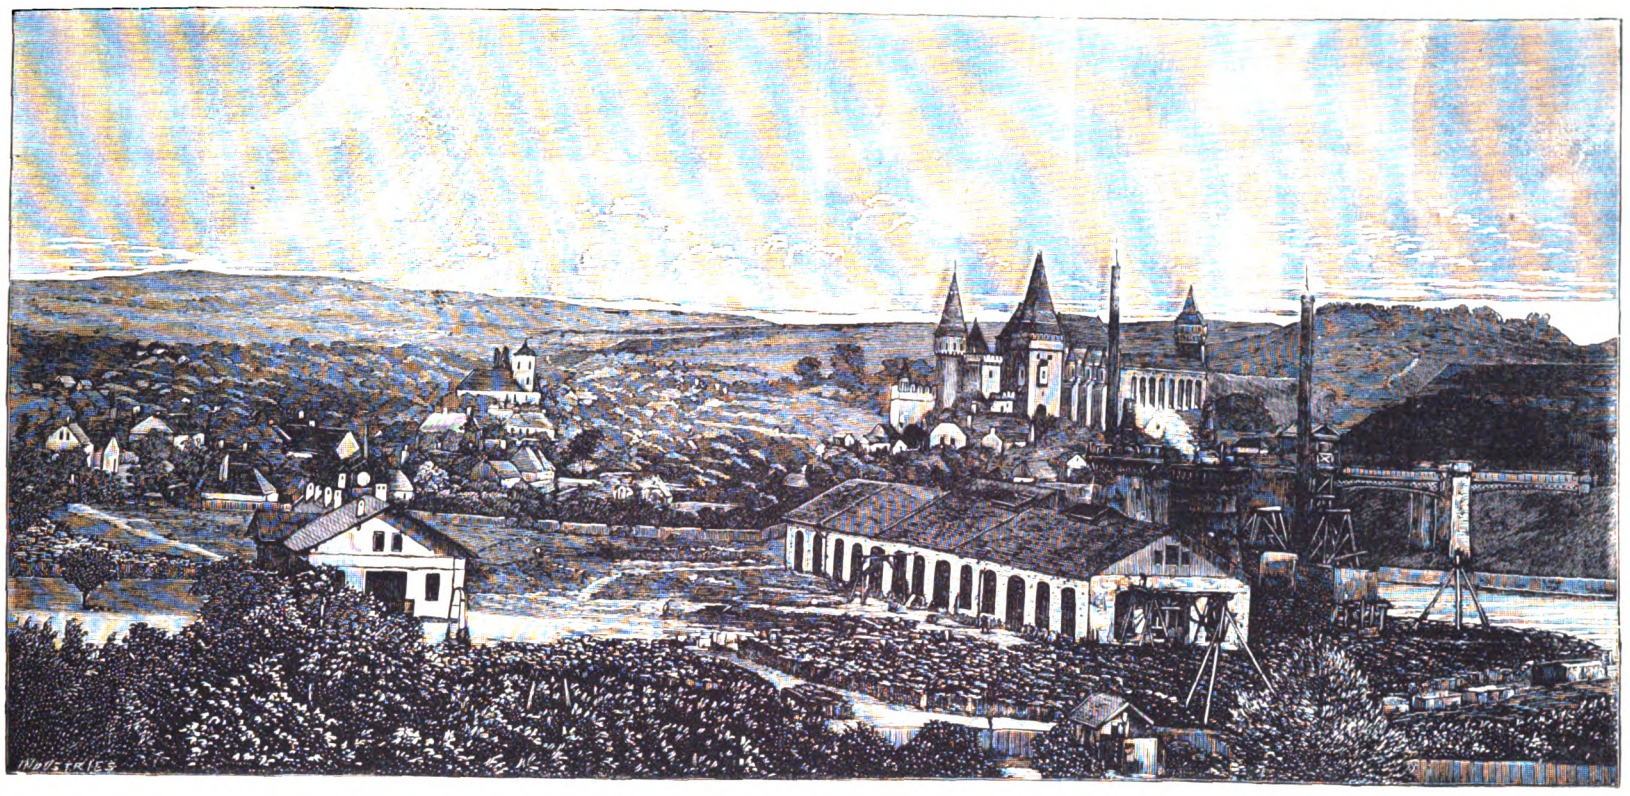
Machine for Shaping Heads of Screws.—*C. F. Roper, Cambridge, Massachusetts.*—This invention consists essentially of a race way to contain the screws, the heads of which are to be shaped, a cut-off slide, and ejector, combined with an intermittently rotating holder, provided with jaws to hold the screws, and with a rotating head shaping tool. The improvements refer to a machine described in Letters Patent No. 162665, granted to the same patentee. The holder is rotated intermittently by a gear wheel, which has three teeth missing at different points of its periphery, so as to place the clamps of the holder in position to have a screw placed therein by the ejector. The holder is composed of a hub, slotted in the direction of its length to receive a series of clamp jaws. A number of punches are pivoted inside the hub, and act by gravity as the holder rotates. The ends of the punches tap against the ends of the screws, and knock them out of the holder. The head shaping cutter is pivoted loosely by a pin in a socket piece. The cutter has attached to it a guide, which is made to pass round the head of the screw before the toothed end of the cutter meets it. The ejector places a screw between the ends of the clamp members while they are separated under the action of a spring, and while the screw is being so placed another pair of clamps, closed firmly upon the shank of another screw, holds it while the cutter finishes the head, the screw so operated on being subsequently discharged from between the clamps before the clamp in the intermittent rotation of the holder again arrives in position opposite the hub of the race way and ejector. The inventor makes six claims for the various combinations of holder, clamps, cutter, and ejector.—No. 372276, dated 25th October, 1887.

Stone Sawing Machine.—*G. M. Viernow, St. Louis.*—This machine is intended more especially for use in cutting solid rock in the quarry, where it is desirable to have a saw which is operated from one end only. The chief improvements introduced consist of the means of driving the saws, and of the manner of feeding as the saw advances in its cut. The two pitman rods are attached to one end of a frame which carry the saws, and the other ends of the rods are geared to cranks which are fitted one at each end of the driving shaft. On the middle of this shaft is a pulley, round which passes the driving belt. In order to increase the grasp of the belt, an attachment is made on the shaft of two arms held together by a spiral spring, with idlers at their ends which press on the two branches of the belt. The feed motion for lowering the saws and their driving mechanism is constructed as follows: Vertical screwed shafts pass through threaded apertures in blocks which support each end of the driving shaft, and rest at their lower ends in bearings in the frame. At their upper ends are bevel wheels, which gear into similar wheels placed on another horizontal shaft. This horizontal shaft carries another bevel wheel, which meshes into a wheel on a hand-rotated shaft, and also a chain wheel, which, by means of a chain, causes a drum to revolve. On this drum is wound a rope, which, passing over a pulley on the end of a crane beam, serves to raise and lower the saws and the ends of the pitman rods nearest to the saws. A handle on the hand-rotated shaft before mentioned is operated by the workman, and serves to lower both ends of the pitman rods simultaneously. The ropes lower one end of the rods, and the other end of the rods is lowered by means of the bevel gear, which causes the upright screwed shaft to turn in the blocks, and in their descent these blocks carry the driving shaft and cranks along with them. The inventor makes nine claims for the improvements.—No. 372996, dated 8th November, 1887.

Converter.—*S. C. Collin, Braddock, Pennsylvania.*—This invention consists of a form of tipping converter, which is so constructed as to dispense with the ladle. The converter is provided with trunnions, by which it is journalled in bearings. One of the trunnions is hollow, and a pipe serves to convey the blast through the trunnion to the end of the converter at which the tuyeres are situated. A crank is fitted to one of the trunnions, and is connected by means of a link to a mechanism which supplies motion to the crank in order to tip the converter when required. A tramway is formed underneath the foundations, and the moulds and waggons for slag run on these rails, and in that position receive their contents directly from the converter. The inventor makes two claims for this form of tipping converter. —No. 372302, dated 1st November, 1887.

Oscillating Engine.—*F. L. Wheeler, Southington, Connecticut.*—The trunnions which support the cylinder are fixed in the middle of its length, and their central line forms a tangent to the circular cross section of the cylinder. The cylinder itself thus supplies the requisite oscillatory motion for the circular slide valves which the inventor makes use of. Steam is admitted to the valve box through one of the trunnions, and leaves the engine through the other on its exhaust. There is also a special system of levers attached to the valve gear for reversing the engine. The inventor makes twelve claims for these combinations of steam chest, valve ports, reversing gear, and the position of the trunnions.—No. 372348, dated 1st November, 1887.

Sewage Furnace.—*A. Engle, Barter, Iowa.*—This furnace is designed for volatilising and burning wet and offensive substances in such a manner as to cause them to furnish fuel for their own disintegration. The annexed diagram represents a longitudinal section of one form of furnace described in the specification. The invention consists of the combination of the fire places C and F with the boiler F¹ and retort G and oven B, for the purposes described. The pipes L L¹ R¹ supply solid garbage for combustion in the oven B, and the pipe K¹ P¹ separates the liquid refuse and conducts it to the retort G. The supply valves and the valves D D¹ being closed, and the valve C¹ being open, the fires are lit at C and F. The flames pass round the oven B, and volatilise the garbage. The resulting



steam and gases pass over the fire place C, and along with the smoke of that fire place through the fire burning at F. During this time the heat of the flames in F has been communicated through the water in the boiler F¹ to the retort G. The refuse therein contained is evaporated, and the gases are conducted by the pipe G¹ to the nozzle H, where they are consumed by the furnace F. When this process has been continued for a time sufficient for the drying of the garbage in the oven B, the valve C¹ is closed and the valve D opened. The flames of the furnace C then pass through the oven B and ignite the refuse. Any unconsumed products of combustion are finally destroyed in the furnace F. The liquid refuse may be sent directly to an oven alongside the oven B, instead of being disintegrated in the retort G, or part of it may be destroyed in the oven, and part in the retort, as in the arrangement shown in the figure. By this invention only a slight sediment is left behind in the retort G. The inventor makes seven claims for the combinations described. —No. 372305, dated 1st November, 1887.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE INDUSTRIAL RESOURCES OF TRANSYLVANIA.

The Government Iron Works at Vaida-Hunyad, Transylvania.

THE INDUSTRIAL RESOURCES OF TRANSYLVANIA.

One of our correspondents, who has travelled in Transylvania with the special object of acquiring a knowledge of the capabilities of the district for industrial development, sends us the following account:—

There are countries in Europe of which much less is known than of South Africa, or any other distant region. Such is the case with Transylvania, a country full of natural resources, waiting to be explored, and practically utilised. Transylvania was the California of the Romans—whose traces we find everywhere in the country—and gold mining is still carried on to a large extent, but as far as I could gather, with very little profit, a result which is natural if we consider the peculiar form and manner of the occurrence of gold in the Transylvanian gold district. Far more important, however, than these gold mines (which have been brought under the notice of the English public, at the time of the gold mining rage in 1881), are the other mineral resources of this country, of which nobody ever speaks, but which I shall now try to enumerate, so far as they have come under my notice during a professional tour through Transylvania last summer.

The basis of all industrial enterprises, cheap fuel, abounds in Transylvania, both in the shape of wood and coal. The whole country is densely wooded, especially the western part of it, where I traversed over a great many square miles of virgin forest. Giant trees of more than 6ft. diam. are very common, but nobody uses them. They die and fall, and on their decaying trunks new life springs forth. Most of these virgin forests consist of pine trees, but there are also many magnificent oak and beech forests. Many of these forests are Government property, others are owned by the aristocracy of the country, who derive a very small income from them. The only reason which can be given for the almost total absence of any attempt to utilise these enormous quantities of timber is the rough and hilly character of the country, and the absence of navigable streams, which renders the removal of the trees from the place of their growth a matter of great difficulty. No attempt seems to have been made to introduce the manufacture of wood cellulose by the sulphite or any other rational process, although I am of opinion that good profits could be realised from such an enterprise in a country where the value of pine wood is next to nothing. The beech forests are utilised for producing charcoal in a very rough and irrational manner. This charcoal is delivered at a ridiculously low price to some of the iron works, of which I shall speak presently.

Coal occurs in very large quantities and in thick strata in several places. Of these, the most important one is Petrozsény, near the Roumanian frontier. Here there are eighteen beds of coal, one overlying the other; and of these, four or five are sufficiently thick to be worked profitably. The greater part of this mining district is the property of the Hungarian Government, who tried to work the mines. This, however, proved a signal failure, so the Government leased their mines to the Kronstadt Mining and Smelting Company, who are also the owners of the mines adjoining the Government property, and who now work the combined coal mines, to considerable advantage, supplying fuel to the Hungarian, Servian, and Roumanian railways, and to some extent also to the Danube steamers. Petrozsény coal is of excellent quality, burning with a long and good flame, and leaving very little ash. It has, however, the drawback of yielding a very inferior coke. Experiments have been carried on for several years to improve the quality of the coke; they have resulted, however, in failure. An iron works with two Scotch blast furnaces, which was built by the Kronstadt Company, at Kalan, in the hope of utilising the Petrozsény coke for the production of pig iron, proved a failure, and is lying idle at the present moment. Petrozsény is connected both with Kalan and the main line of the Transylvanian Railway by a branch line, which leads through one of the most picturesque mountain districts of Europe. Recently, a new bed of tertiary coal was discovered in the north-east of the country, in the neighbourhood of Bistritz. The quality of this new coal is said to be very good, but the nature and extent of the occurrence is as yet hardly known.

The mineral wealth of Transylvania is astonishing, and probably superior to that of any other European country. The frequent occurrence of gold has already been mentioned; it has been an object of industrial enterprise ever since the times of the Romans. The gold occurs both in a free state and in combination with silver, lead, and tellur. The peculiarity of Transylvanian gold is that it is not contained in quartz, as in many other gold bearing districts; nor is it mixed with the sand of streams which spring from auriferous quartz mountains; but the gold occurs in the shape of sublimed crystals in fissures of volcanic rocks, especially trachyte. These fissures have subsequently been infiltrated with carbonate of lime, which encloses the gold crystals. The fissures never exceed 5in. or 6in. in thickness, and generally they are much thinner. In order to get at the auriferous calcite, large quantities of trachyte, which contain no trace of gold, have to be removed; consequently, gold mining in Transylvania is connected with an unusual amount of work, and cannot leave the result profitable. Besides the Government mines, there are also a few gold mines belonging to companies or private individuals. Of the Government mines, the most important one is Nagyag, situated at the summit of a very steep mountain. There the gold occurs only in combination with silver, lead, and tellur, in the shape of sylvanite and nagyagite. Nagyag is the only place in the world where tellur is found in quantity. All the gold ores, from Nagyag as well as from the other gold mines (where gold occurs in the metallic state), is brought together to Zalatna, where the gold is extracted and refined. The tellur is volatilised during the operation of extraction, and is deposited in the shape of crude tellurous acid in certain chambers connected with the furnace. If tellur should, as it seems likely to, be capable of finding a useful application in electricity, then Zalatna would probably be the only place in the world where it could be obtained.

Silver and lead occur, as I have already mentioned, in combination with the gold at Nagyag; but they are also found in the shape of argentiferous lead ore, which is worked up together with the gold ore at Zalatna. There is also a lead and silver smelting works at Deva. Manganese ores are very plentiful, and magnificently crystallised pyrolusite occurs in various places. I am not aware, however, of the existence of any manganese mines. The same is the case with certain minerals of baryta and arsenic. Iron ores occur in many places in great quantity and of excellent quality. Transylvanian iron ores are remarkably free from phosphorus. Several works exist in which these ores are worked up in charcoal blast furnaces. The pig iron obtained is of excellent quality, and quite as good as the best Styrian iron. It used to find a ready market for the manufacture of steel and wrought iron. At present, however, iron smelting in Transylvania is no longer profitable, because the introduction of the Thomas-Gilchrist process has considerably lowered the value of pig iron free from phosphorus. The largest Transylvanian iron works is that of Vaida-Hunyad, and is Government property. At the time of my visit to this works, a stock of pig iron was to be seen which no private company would dare to accumulate. Even the Government engineers seemed to be uneasy about it, and a steel making plant was being put up, so as to utilise this enormous quantity of pig iron. The above engraving, which is prepared from a photograph, shows these iron works. The low, long building in front is the foundry, and behind it are two blast furnaces. The establishment is connected by an overhead steel rope way, with the collieries nineteen miles distant; and the iron ore mines are situate on the same track, at a distance of six miles from the furnaces. The building at the end of the foundry contains the blast engines, and the offices are on the opposite side of the yard. The building on the hill is the famous castle Vaida-Hunyad—built by Johannes Corvinus—the birth place of Matthias Corvinus, and for centuries the residence of the Grand Dukes of Transylvania. It is now the property of the Austrian Emperor, who received it as a free gift from the Hungarian nation.

Digitized by Google

Another iron works is that of Roskitza, which belongs to the Kronstadt Company. Its produce is transformed into wrought iron at Ferdinandsberg, another of the same company's works. Ferdinandsberg wrought iron is generally known and liked all along the Danube, in Servia, Roumania, and even in Turkey. The Ferdinandsberg puddling furnaces are heated by gas, obtained in a peculiar generator from beech wood. Both at Hunyad and Roskitza the iron ore occurs in the immediate neighbourhood of the works. I have already mentioned the blast furnaces at Kalan, which had to be abandoned, being constructed for the use of coke, and situated in a valley where charcoal made from beech wood cannot be obtained as cheaply as in Hunyad and Roskitza. There is, however, still some iron casting carried on at Kalan. Domestic iron stoves are produced, which find a ready market in the neighbourhood.

Large quantities of china clay occur in two extensive beds in the neighbourhood of Deva, but nobody thinks of using them. Ordinary clay occurs everywhere, and yields the raw material for a rough kind of pottery carried on by Wallachian peasants, who have, in the shape of their productions, most faithfully preserved the Roman traditions.

There are beds of rock salt of astonishing size and depth in various places. The most important of these is the one situated at Maros-Ujwar, where the colour of the rock salt is almost white, and large transparent cubes of salt are of common occurrence. The salt mines I visited are those of Viszakna, in the south of Transylvania, and in the immediate neighbourhood of Hermannstadt, a city of 30,000 inhabitants of Saxon origin. At Viszakna the Romans have left evidence of rock salt mining. Their pits were of a conical shape, enlarging as they descended. The natural consequence of this irrational mode of mining was, that the pits fell in after a while, forming very deep funnel-shaped holes, which becoming filled with rain water were in the course of time transformed into small lakes of saturated brine. These lakes are now used for bathing, and wonderful cures are said to have been effected by the brine in cases of severe rheumatism and gout. No other use is made of this brine, although it would be a suitable raw material for the manufacture of soda by the ammonia process, with the use of cheap coal from Petrozsény or Bistritz. In the immediate neighbourhood of these lakes is a modern salt pit, worked by the Hungarian Government, who have made the mining of salt a State monopoly. This mine descends to a very great depth (there are some 350 steps leading down into the main gallery), and then widens out into a succession of halls with galleries hewn into the solid rock salt. The mine is only worked during winter time, when it gives employment to the agricultural labourers. The salt is hewn away in the shape of large rectangular blocks, which are hoisted up by means of buffalo hide bags, attached to a long rope. There is a primitive mill connected with the mine, where the rock salt is ground into a powder, which is sold for domestic purposes. The Transylvanian salt mines seem to supply all the salt used throughout Hungary, and in the shape of ground rock salt. Crystallised salt, prepared by the evaporation of brine, seems to be an unknown luxury throughout the kingdom, and even in first class hotels only the ground rock salt is to be found.

In the immediate neighbourhood of Transylvania, in the famous Tömös valley, in Roumania (where the king's well known summer residence, Sinaia, forms an attraction for tourists), petroleum was discovered a few years ago, and it is more than probable that it will also be found on this side of the frontier. At present it is brought over from Roumania by rail, in a crude state, to Kronstadt, where two or three small refineries are employed in its purification. The rectified oil is sold for domestic purposes throughout Hungary. Kronstadt is a city of about 35,000 inhabitants, and the only place in Transylvania where some attempts at industrial enterprise are made. Besides the petroleum refineries mentioned, there are two large distilleries and a paper mill. The latter is said to use, amongst other raw materials, the straw of Indian corn, which is grown in extraordinary quantity everywhere in the south of Hungary and in Transylvania. There is quite as much, if not more, Indian corn grown in the country as there is wheat. Indian corn forms the chief and favourite food of the Wallachian peasants, who make a peculiar kind of yellow bread from it, which tastes very unpleasant to a civilised palate. Indian corn is also, as has been shown in the United States, an excellent raw material for the manufacture of starch and spirit.

From the above sketch it will be seen that Transylvania is full of industrial opportunities, which, hitherto, have not been utilised. There are various reasons for this. The most important one seems to be the total absence of capital. I have met with very little poverty during my voyage in Transylvania; neither have I met with or heard of a single rich man. The aristocracy of the country are certainly very rich, if we consider the extent of the land they own; but their income derived from this property is barely sufficient to keep them. Moreover, they are all Magyars, a race whose want of industrial enterprise is almost proverbial. The Wallachians, who form by far the majority of the inhabitants of Transylvania, are all either peasants or agricultural labourers. They are good natured and hard working, but almost invariably illiterate and wanting in intelligence. The most intelligent race in Transylvania are the Saxons, who form three separate large colonies, Kronstadt, Hermannstadt, and Bistritz. They are leading a quiet and happy life, having enough for their wants, but nothing to spare. They do not seem to understand the importance of industrial enterprise; and being in constant opposition to the Hungarian Government, they have very little inducement to go in for work in which they would be largely at the mercy of that Government.

Another reason for the absence of industrial enterprise in Transylvania is its comparative remoteness. It is true that Transylvania is connected with the surrounding countries by railways. But, on the other hand, the rates for goods traffic to great distances are anything but encouraging, whilst the once existing outlet for Transylvanian goods into the adjoining kingdom of Roumania is at present entirely blocked by the "zollkrieg," a system of prohibitive tariffs enforced by Roumania upon Hungarian goods, and *vice versa*. Ever since the existence of this "zollkrieg" the commerce of Transylvania has been in a ruinous condition. Finally, it must be mentioned that the peculiar geological formation of Transylvania is such that there are very few important water courses in the country. The absence of water in the otherwise most magnificent mountain scenery of the South Karpathic range is quite striking to anyone conversant with other European mountain districts. On the summit of some of the highest mountains there is generally one or a couple of small but very deep lakes, without visible outlet; but even in the deepest ravines and valleys there is frequently a mere suspicion of a brook, where, in a similar locality in Switzerland, there would be a raging torrent. This scarcity of small water courses in the mountains very naturally results in a corresponding insignificance of the streams in the plains. This is an item to be considered by all who intend to go in for industrial undertakings in Transylvania.

At present the Hungarian Government are the only proprietors of industrial enterprises in Transylvania worth mentioning, excepting the Kronstadt Company, which is in the hands of a few large Vienna capitalists. It is difficult to state how these Government enterprises prosper. On an average they may be assumed to fairly pay their way. It is, however, generally acknowledged that Government enterprise is almost the worst method to utilise natural opportunities. Even the most zealous and intelligent Government officials will always lack that enterprising and active spirit which is the first condition of industrial success, whilst the unavoidable red tape stifles even the last trace of a pushing spirit which might now and then actuate the officers in charge of the works.

UNIVERSITY EXTENSION AND TECHNICAL EDUCATION.

By Henry Dyer, C.E., M.A.

II.

(Continued from page 78.)

In this country opinion has been almost unanimous against attempting to teach trades in schools, and has insisted on these being taught in actual workshops or manufactories. In some trades, however, especially those requiring a high degree of manipulative skill, the practice in the workshop may with advantage be supplemented in evening classes; but the expense of these should be borne by those most interested in them, and not either by local rates or Imperial grants. Professor Fleeming Jenkin, speaking on this subject, said: "If you mean by technical education, attempting to teach a man his business by a college course, I think it is a very mischievous delusion indeed; but if you mean by that, in addition to his practical training, you would give him some theoretical training, some technical courses, I think it would be very useful indeed." If, then, we define technical education as a training in the applications of science to special departments of industry, and, of course, presuppose that the students have had fair opportunities of obtaining a knowledge of the theoretical principles involved, we see at once that it falls within the legitimate sphere of university work, not only in its higher but also in its most elementary departments. The universities have for some time held local examinations in the elementary departments of literary and scientific subjects, and there are no reasons why these should not be extended to applied science, as a sufficient board of examiners might be appointed which would be competent to deal with all the subjects required in the districts covered by its operations. The Victoria University has made arrangements for undertaking work of this kind, and has opened a register for technical schools, mechanics' institutes, and the like, so that their students may be examined in the different departments of applied science; and no doubt the movement will extend, as it has done in the case of the literary and scientific subjects in Cambridge, so as to lead to the recognition of the work done in the local institutions for a part, and possibly in the not very distant future, for the greater part of the degree examination. This step taken by the Victoria University is another illustration of the fact that the newer institutions are more anxious to keep themselves up with the spirit of the times than are the older. In this matter the authorities concerned, in formulating their scheme have acted upon the advice of practical men, and men who were best competent to give counsel on the subject, an example which might with advantage be followed by the older institutions.

We have throughout the country an extensive system of teaching and examination in connection with the Science and Art Department and the City and Guilds of London Institute, which ought to be utilised and improved as far as possible. I do not wish to deny that some good work has been done by both of those systems during the past few years; but even their warmest admirers admit that there has been a great deal of very bad work. Both systems labour under all the disadvantages of what is known as "payment by results," but should be called "payment by passes," which is quite another thing. These disadvantages are evidently realised by those in charge of the arrangements, for at the last meeting of the British Association I heard Sir Philip Magnus, the Director and Secretary of the City and Guilds of London Institute, say, when asking his audience to consider the proposals of the Technical Schools Bill, that he hoped that nothing would be done to extend the fetters of the method of payment by results, while the examiners of the Science and Art Department have always tried to minimise the evils connected with it. The whole system, however, must be changed, for the principles on which it is founded are unsound. There must, of course, be payment by results, but not by the results of individual students, but rather of the average work done in a district; and moreover there must be a decentralisation of examination, or the present system will break down through sheer weight. Want of space in the meantime, however, prevents me from entering into details of this part of the subject, and I would simply indicate that the different Universities should be made the centres of educational districts, and the local examinations be conducted from these centres, aided, of course, by the most competent persons in the different localities. The subjects in the syllabuses of the Science and Art Department and the City and Guilds of London Institute represent very fully those for which classes should be instituted; but each educational centre should issue its own syllabus. Even these should not attempt to bind the teachers as to the details of subjects and methods of teaching; but considerable latitude should be given, so that variety of treatment might be possible and the originality of the teachers and scholars developed, as well as modifications introduced to suit local circumstances.

The unit of the organisation required should be the public elementary school, in which would be laid the foundation for technical subjects in as good a general education as could be given within the limits of age prescribed. In the evening classes of these, in the secondary schools, and in special scientific institutions, such as technical schools and colleges, more advanced classes would be formed. Under the Technical Schools (Scotland) Act, the Scotch School Boards will have extended powers for organising and maintaining such classes, and it is probable that in a short time English School Boards will have similar powers. The most promising students would pass from the evening classes to the day classes of a College or University, which would also be attended by some of the best students from the secondary schools. Those who had gone through a full course of study in the evening classes should be allowed to proceed to a degree after a comparatively short attendance at the day classes, on condition, of course, that they passed all the examinations required. This they would have no difficulty in doing, as those who had ability and perseverance enough to complete the evening classes curriculum would be far above the average College or University student who attended the classes by his father's orders, and not because his heart was in his work.

This outlined scheme is no mere dream, for in the West of Scotland we are within a short distance of making it a reality, if only a few more comparatively simple steps were taken. The constitution of the Glasgow and West of Scotland Technical College is such that it allows students to pass from the most elementary to the highest classes. At present, its evening classes are conducted according to the requirements of the Science and Art Department; but it is to be hoped that these will ultimately be modified in the direction I have indicated. For these classes, complete courses of instruction extending over four years have been arranged in the following

Digitized by Google

departments: (1) Mechanical engineering; (2) naval architecture; (3) electrical engineering; (4) architecture; (5) building construction; (6) chemical industries; (7) metallurgy; (8) mining; (9) agriculture; (10) textile industries; and students who complete them will receive the College certificate, while those who take an additional year at the day classes will obtain the College diploma, which can also be got after three years' attendance at the day classes alone. For both the day and evening classes certificates of attendance are accepted from any properly organised institution, or from teachers of known ability. The College, which was formed by the amalgamation of Anderson's College, the College of Science and Arts, and Allan Glen's School, has just been inaugurated, so that as yet no arrangements have been made for the institution of branches in Glasgow and the West of Scotland; but throughout that district numerous classes already exist in connection with the Science and Art Department and the City and Guilds of London Institute, and it is probable that these will be extended, and many more founded. It is to be hoped that, instead of working as isolated units, these will be formed into one system, in which the great body of the students will obtain all they require, but from which the most promising would pass by means of bursaries or otherwise to the day classes of the College, or of the University.

It will be observed that only one further step requires to be taken to make the system reach from the lowest class in the elementary school to the highest class in the University, and that is the recognition by the authorities of the University of the attendance required for the diploma of the Technical College, as equivalent to the greater part of what is required for a degree, and it is to be hoped that they will see that it is their duty to take this step at the earliest possible time. It may be argued that such a step is still premature; but all educational history shows that unless the highest institutions take the lead, and encourage and maintain a good standard of teaching and examination, the lower have a sickly existence. The possibility of obtaining a degree would infuse life and energy into the students, and give them an object in their studies, which would be the means of doing more good to the local institutions than a large addition to their endowments. No favour is asked, as the students would in all cases be required to attend systematic and lengthened courses of instruction, and to pass whatever standard of examination might be decided upon, and that being so, and the Universities being public institutions for the advancement and spread of learning, it is evidently their duty to lead the new educational movement which is everywhere rapidly developing. In these democratic days privileged monopoly cannot exist, and the Universities must clearly recognise that they cannot retain at the same time the positions of national institutions and private establishments. I do not think that there will be any wish to lower the standard of work in the Universities, or to make the position of professor any less honourable. On the contrary, I believe the educated public will see the necessity for giving encouragement to every department of learning in all stages, of making the professors independent of competing for fees or grants, and of making their position as honourable as possible; but it will insist as a return for all this on them efficiently meeting the demands of the times in every department of education, and it will expect those who occupy high educational positions to lead and guide public opinion in all educational and social questions, and not simply allow themselves to drift before it.

(To be continued.)

THE INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting held on the 24th of January, a paper was read on "The Erection of the 'Jubilee' Bridge carrying the East Indian Railway over the River Hooghly, at Hooghly," by Sir Bradford Leslie, K.C.I.E., M.Inst.C.E. The author stated that this bridge carried a double line of railway, of 5ft. 6in. gauge, over the Hooghly River, which, at the site of the bridge, was 1200ft. wide, with a depth of 86ft. at high water spring tides in the flood season. The bridge had a clear headway of 33ft. 6in. above the highest tides, or 54ft. above low water in the dry season. Excepting in the deep channel on the right side, the river flowed over a bed of silt, which was very unstable and subject to scour. This, together with the strength of the tidal flow, and the periodical floods, five or six miles an hour, was very unfavourable to the use of any kind of temporary staging in the river bed. Taking into account the danger of any such staging being carried away by the unwieldy country craft navigating the river, it was considered advisable to dispense, so far as possible, with the use of staging or false work for the erection of the superstructure of the bridge, and the general design was arranged accordingly. A central double cantilever, 360ft. long by 52ft. high over all, was supported by two piers 120ft. 6in. apart from centre to centre. The piers were 66ft. long by 25ft. wide, with semi-circular ends and flat sides, and were sunk by means of iron caissons of the same dimensions, and each 108ft. high, 70ft. into the river bed, and rested on a stratum of hard yellow clay, into which they penetrated 12ft. The caissons were divided by four cross partitions into three excavating chambers, open from bottom to top, and two intermediate water tight compartments. They also had lateral water tight compartments in the central excavating chamber. The weight of iron work in each caisson was 453 tons. They were built in rings 4ft. deep, connected by internal angle irons. The lower length of 16ft. of each caisson was built on shore, and was launched and floated into position at the site of the pier. Here the caissons were moored by chain cables and anchors, with the assistance of a pair of coupled pontoons occupying the space between them. These pontoons formed a working platform for the erection, pitching, and sinking of the caissons. The caissons were built up of the 4ft. rings, and weighted with brick work and concrete until the lower edge approached the river bed at low water; they were then adjusted exactly true to position, and pitched by admitting water into the water tight compartments, which were afterwards filled with cement concrete and brick work. The caissons, when pitched, were sunk into the river bed by removing the earth from the interior through the excavating chambers, by means of special boring apparatus similar to that used at the Gorai Bridge on the Eastern Bengal Railway. When sunk to the full depth they were filled with cement concrete and brick work, and the piers were built of brick work up to a height of 34ft. above high water. Upon the brick piers, and connected with them by holding down bolts and anchor castings bedded in the brick work, were erected cellular steel standards 30ft. high, each weighing 205 tons. These completed the piers up to the under side of the cantilever girders. For the erection of the central portion of the cantilever, 180ft. long, a staging constructed of timber and rails, and springing from the brick work of the river piers, was constructed. Upon this staging the cantilever was erected by means of derricks 70ft. to 90ft. long, guyed from the pontoons, which were moored to the piers, and from buoys laid for the purpose. The end portions of the cantilevers, projecting 90ft. beyond the timber staging, were erected by first placing in position a 30ft. length of bottom boom with gusset plates attached, and suspending it temporarily by tackles to the completed portion of the cantilever, then raising and fixing the inclined suspension bars, and afterwards the vertical struts and sections of the top boom, thus completing the 30ft. panel or bay. The erection of the cantilever complete, including riveting, weighing 1465 tons, occupied six months, and was carried on while the river was in full flood. The two side abutments of the bridge were built of brick work and concrete; they were rectangular in plan, 65ft. long by 28ft. wide at the base, reduced to 42ft. long by 15ft. wide at the top. They were founded by means of wrought iron curbs, 8ft. deep, divided by cross partitions into three excavating chambers, with openings 6ft. by 12ft., through which the earth was removed from inside the curb. The right abutment was sunk through clay to a depth of 40ft. below ground level. As but little water leaked in, the material was excavated by hand digging. The left abutment was sunk through silt to a depth of 84ft. below the ground level. The borings showed no better foundation, even at a depth of 140ft., and as further sinking would have required an enormous weight to overcome side friction, it was stopped at this depth. The water percolated freely through silt, in which this abutment was founded; it was therefore excavated by Bull's dredgers, worked by steam winches. When sunk to the full depth, the excavating chambers of both abutments were filled with concrete and brick work. Approach viaducts, 450ft. long, were built of brick work on both sides of the river. The piers of these viaducts were 4ft. 1in. thick, 15ft. apart from centre to centre, the intervening spaces being spanned by semi-circular arches. The viaducts were 37ft. 9in. wide at the top over all. In rear of the left abutment of the main bridge, the ground had been disturbed by the excavation of the silt from the chambers of the abutment curb, drawing in the stuff from the back and undermining it. To bridge over this disturbed area, it became necessary to have recourse to a block foundation 60ft. square, with twenty-five excavating chambers, from which the earth was removed by dredging. This 60ft. block was sunk to 20ft. below ground level, and the excavating chambers having been filled with concrete, the approach viaduct was built upon it. Upon the spandrel or side walls of these viaducts, the steel girders of the main side spans, 420ft. long by 47ft. deep, of a weight of 1000 tons per span, were erected and riveted up complete. For launching them into position, four flat footed or Vignoles rails were laid in juxtaposition on three longitudinal balks of timber on the viaduct walls under the centre of each of the main girders. These lines of rails extended the whole length of the viaduct and over the abutments, projecting 3ft. beyond the face of the same. The shore or rear ends of the main girders, weighing 250 tons each, were carried on trollies by means of the end bearing pins. The trollies distributed the weight over a wheel base of 22½ft. A roller platform, resting on fourteen 3¾in. round iron rollers, was inserted under each of the main girders at a distance of 60ft. from the outer or river end, the girders being stiffened, by temporary counter-struts in two bays, to sustain the abnormal strains due to their being supported 60ft. from the end. The main girders, thus carried on the roller platforms and trollies in the rear, were then hauled out until they overhung or projected beyond the abutment 51ft. The two pontoons used in sinking the caissons of the river piers, each 225ft. long by 26ft. 6in. wide by 9ft. deep, with a combined displacement of 300 tons per foot of immersion, were closely coupled together and rigidly connected by a strong staging of timber and rails, designed to carry the girders of the main side spans, supporting them at the outer end and at a point 30ft. from the end, at a height of 48ft. or 50ft. above the water level. The pontoon staging thus prepared was floated under the projecting ends of the main girders at low water on a suitable tide, and the packings having been adjusted to distribute the weight equally on the two pontoons, the outer ends of the girders were lifted by the rising tide, and the shore ends being carried on the trollies, the girders were hauled across and deposited on their seat at the cantilever ends. The pontoons with the staging were removed at low water. The operation of launching or floating out each main side span occupied about an hour and a half. The hauling out gear consisted, first, of two three-fold 1in. chain tackles, made fast to the outside of the abutments and hauling on the shore end of the girders, operated by a pair of semi-portable engines fixed on the approach viaduct in rear of the girders; and secondly, of three double steel 4in. wire ropes (six parts altogether) attached to the deck of the outer end of the main girders, hauled on by rope tackles ranged on the cantilever deck, and worked by powerful steam winches. During the operation of floating out the main girders, the pontoons were guided in a straight line, and prevented from drifting sideways by up and down stream warps made fast to barges moored at a suitable distance above and below bridge; the warps were hauled in or paid out from capstans on the pontoon decks. After the main girders had been placed in position, it was necessary to remove the launching trollies from the shore ends, and to transfer the girder ends to the pendulum suspension links by which they are permanently carried, and which allow of expansion and contraction of the girders due to variations of temperature. The first caisson was launched on the 2nd of March, 1884. The second side span was floated into position, and the shore ends were suspended by the pendulum links to the saddle castings on the abutment, thus practically completing the bridge, on the 22nd December, 1886.

NOTES ON SCREWING APPLIANCES.

(Continued from page 80.)

Gas Master Taps.—These taps are only used for finishing the dies of screwing machines or of guide screw stocks; their outside diameter is exactly twice the depth of the thread greater than that of the ordinary gas tap, for reasons already explained.

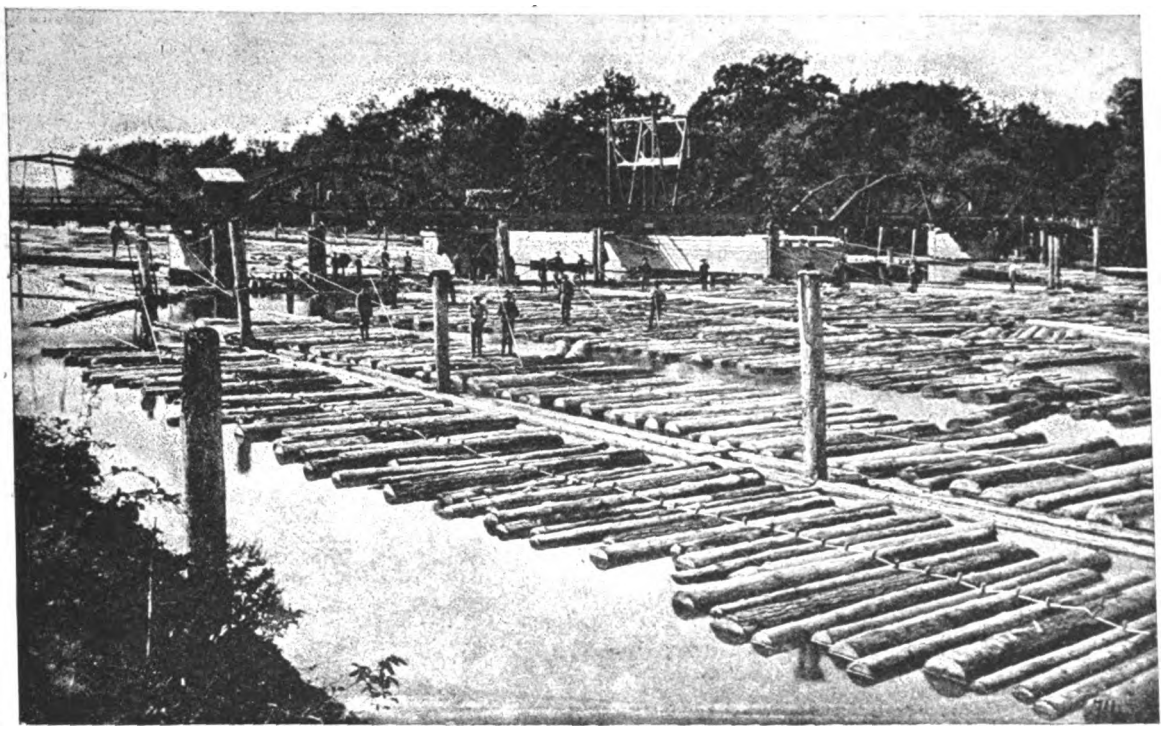
Manufacture.—The first step in the making of taps is to heat the steel bars and saw them off to the required length; the necks are then forged to the required size, and

Digitized by Google

LOGGING IN CANADA.



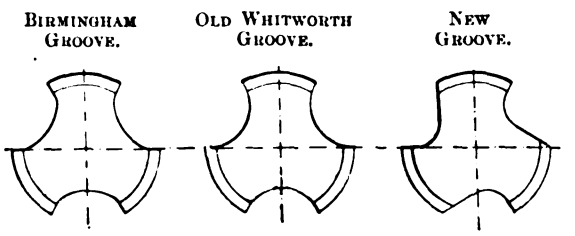


FIG. 8.—A SORTING BOOM.

the forgings carefully annealed to soften and make them easier to cut, and to relieve any strains induced in the outer skin of the steel by forging, so that they may be less likely to warp or bend in hardening. It does not follow that the higher a piece of steel is heated the softer it will be when cooled, no matter how slowly it may be cooled, therefore there is nothing to be gained by heating a piece of steel hotter than a bright cherry red. On the contrary, it would be rendered brittle and liable to crack in hardening, and the threads would, after hardening, not be nearly so durable as if it had been annealed at a lower heat; in fact, the steel has lost that almost undefinable property called "body." For the purpose of annealing the taps should be placed in a furnace and raised to not more than a cherry red heat, and then slowly cooled. After this they are centred by one boy and passed on to another, who turns them to the proper length, after which the part to be screwed is rough-turned; they are then laid aside to be inspected for seams or "roaks,"—those taps which are defective in this respect being turned down to make smaller taps, and if they will not do this, they are sent back to be re-melted. The next operation is to turn the neck of the tap to the proper diameter and length, and cut a fine line as a guide for length of square. When this is done, the taps are placed in an automatic centreing and gripping chuck on a small shaping machine (no setting is required), and the thread end is placed in the chuck and forced into it by a loose headstock; each side of the square is then cut at one operation, and the machine stopped automatically at the proper point; in this way the length of each side of the square is made precisely the same without any attention on the part of the boy in charge of the machine. The taps are then screwed to slightly below the standard gauge and passed on to the grooving machine.

TAP GROOVES.—The grooves of any tap should always be of uneven number, so as to keep the tap steady in the hole, and they should obviously be of such a form and size that the least possible force may be expended in tapping a hole and withdrawing the tap. The grooves should contain all the cuttings without wedging the tap. There are three distinct forms of groove cut by different makers, as shown in Figs. 5, 6, and 7. That shown in Fig. 5 has the cutting edge a radial line, and so far is a very good one; but it frequently happens that on withdrawing the tap the cuttings get jammed, and it has the objection that it will not easily contain all the cuttings; this latter defect could be remedied by making the grooves deeper, but then the tap would be rendered too weak for its work. Fig. 6 shows a groove which has been in use for many years, and is such that it leaves little room for improvement. This is a segment of a circle, and the circumference of the tap is divided equally into six parts, the widths of thread and groove being equal. The diameter at the bottom of the grooves is $\frac{9}{16}$ths the diameter of the tap; this groove contains all the cuttings without difficulty, and being symmetrical, the force necessary to withdraw the tap is comparatively small, and much less than for a tap grooved as in Fig. 5. The only objection is that the cutting edge, though radial at the top of the thread, is an obtuse angle at the bottom of the thread, and consequently not the best for easy cutting. The groove in Fig. 7 has this defect remedied, for the cutting edge is radial from top to bottom of the

FIGS. 5, 6, AND 7.—WORKING TAPS.

thread; it also gives more room for the cuttings without perceptibly weakening the tap, and may fairly be considered the best groove possible. Years ago, the three grooves were cut at one operation by a machine specially constructed for the purpose; but it has been abandoned by most tap making firms, and now each groove is finished separately, and the three-groove machine used only for roughing out. The thread is then backed off with the file, and the taps are ready for hardening.

HARDENING AND TEMPERING.—This is an operation requiring some care, for if the taps are too hard they break in use, and if too soft they do not wear well. Again, if proper care is not taken in the hardening, the taps may be bent, and once bent, they are not easily straightened. They should be uniformly heated in a coal or gas fired furnace, preferably enclosed in a box of charcoal to protect them from the action of the air, and so prevent scaling. If, however, the furnace is properly managed, there will not be much trouble; they must be left in the furnace for a short time after they have attained the proper heat on the surface, so that they may be of the same heat all through, as any inattention to this point may result in cracking. The heat to which the steel should be raised will vary slightly for different steels, and must be determined by experiment; but in no case should they be made hotter than a full red. When ready for slacking they should be lifted separately by a pair of tongs, and held in a vertical position whilst plunged screwed end first into a tank of water at 80°F., and held there until quite cold; if they are taken out before this there is a great risk of water cracking, and if they are plunged into this tank in any other position than a vertical one, they will almost certainly be bent, owing to irregular cooling and contraction. If moved about in the tank to hasten the cooling, they should be moved up and down and not sideways. It is of the utmost importance that the water should be warm, as probably more taps are cracked along the grooves from inattention to this point than from all other causes put together. Before tempering, one of the grooves is polished on a leather buff, coated with emery powder. If there are not many taps to temper, the best way of heating them is to hold them in a red hot iron ring and move them about along the tube to heat them slowly and regularly, and when the polished groove becomes light straw colour, plunge them in water as before. If there are large numbers of taps to harden, they may be heated in a lead bath or in an oil bath to which a pyrometer is attached, and when they have been heated to the proper temperature as indicated by the pyrometer, they are plunged into water; but for the latter process it is not necessary to polish the grooves. The latter methods do not, however, give the same general satisfaction as when the taps are heated separately, but are often preferred on account of the saving in time and fuel. The squares of the taps are always tempered at a blue heat, to give them greater toughness, and so prevent fracture in the corner of the square. Some steels expand more than others in hardening, and thus cause trouble in getting all the taps of the proper size; it is, however, very easy to test a piece of each batch of steel delivered for expansion, and allow for it in cutting the thread; but in works where large numbers of taps are made, this gives rise to considerable inconvenience, and generally, if all the steel is carefully annealed before use, there will be very little trouble from different amounts of expansion in hardening. After tempering, the tap grooves are polished on a leather buff coated with emery, and the necks and ends in a small polishing lathe, when they are ready for sale.

STEEL FOR TAPS.—The selection of steel for any cutting tool is a matter of great importance, and cannot be too carefully attended to. There are several kinds in use for taps, and of these there is none better than good crucible steel, which has been carefully melted and had sufficient work done on it under the rolls or tilt hammer. A large amount of Siemens steel is used for taps, and also some Bessemer steel. A special soft centre steel is also greatly used for taps. It is made by placing soft ingots in a cementation furnace until the outside has absorbed sufficient carbon—about $1\frac{1}{2}$ per cent.—to make it hard enough for its purpose; the centre of the steel is softer than the outside, and is said to increase the strength of the tap after hardening. The first thing to be careful about is that the steel is of the right "temper," that is, that it contains the proper amount of carbon to fit it for the work it has to do, as nothing is more common than for steel to be rejected as bad in quality, because it has been used for a purpose for which its temper was unsuitable. The treatment of the steel from the ingot to the rod is also a matter of the highest importance; it should never be made too hot, a suitable amount of forging should be done on it at each heating, and as the forging of round bars under the hammer has a tendency to produce rottenness at the core and subsequent cracking in hardening, the steel for taps should always be rolled to size.

(To be continued.)

LOGGING IN CANADA.

IV.

(Concluded from page 81.)

WHEN the timber, after being driven down a side stream, as described in the last chapter, reaches the main river, it falls in, and becomes mixed, with logs belonging to other firms, which have arrived from the numerous tributaries. All the logs are allowed to float along indiscriminately until they reach a point where they are to be sorted previous to delivery. To this end, they are gathered into a "boom," which is merely a water enclosure formed by timbers strung together endwise, and held in position by piles driven into the bed of the river at suitable intervals. The boom is sub-divided into several smaller enclosures, designated "pockets." These are ranged usually on either side of the boom, each having an opening towards the centre of the main enclosure. Down this centre channel all the logs are floated as they arrive, and men stationed at the opening of each pocket examine the logs, and after indentifying them by the marks (made by the log makers, as previously explained) pass them into the pockets apportioned to the firm or company to which they belong. Fig. 8 illustrates such a sorting boom. In such a vast accumulation of logs, it naturally happens that a considerable number arrive which cannot be identified, on account of their marks having been obliterated during their long journey. These are put into a special pocket set apart for "stray" logs, and sold once a year to the highest bidder on account of the boom company. After being sorted the logs are formed into rafts, and towed down the river by steamers to the various saw mills, where they are to be converted. These rafts are sometimes made by simply enclosing the loose logs by a string of timbers joined endwise, thus forming a sort of movable boom; but more often each log is made fast to the next one by means of a sort of wooden staple, called a "rafting pin," through which a

Digitized by Google

LOGGING IN CANADA.

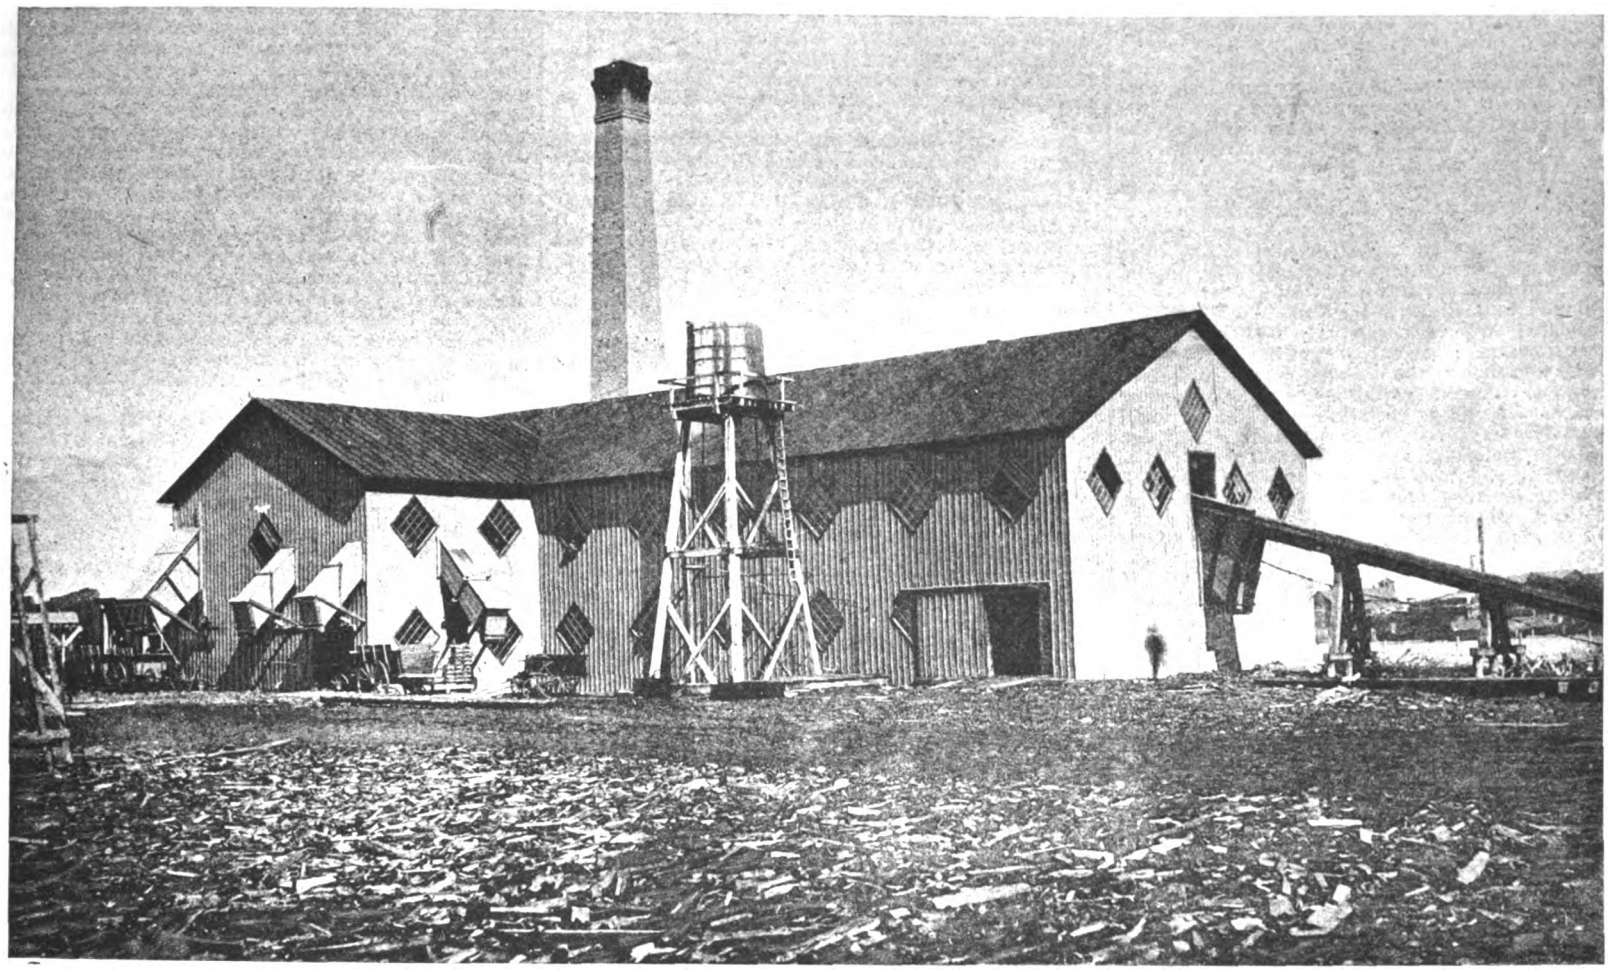

FIG. 9.—A SAGINAW SAW MILL.

rope is passed. This latter plan is preferable to the former, as the logs being individually fastened, they would, at all events, keep more or less together in the event of a rope breaking, whereas, in the other case, if the enclosing ring were to be broken, the logs would be all liberated, and would cause much trouble and expense to collect again.

One steamer will tow a number of rafts simultaneously, and men ride down on the latter for the purpose of detaching and delivering them at their respective destinations, which they do without stopping the progress of the main body of timber. After safely placing the consignment in the hands of the saw mill men they catch up the remainder of the raft by boats. A raft containing 1,000,000ft. of timber is looked upon as one of ordinary dimensions, but rafts made up of three or four times that quantity are found quite convenient to manipulate, although they cover, perhaps, 8 or 10 acres of water. As far as the writer knows, the largest raft ever floated contained about 8,000,000ft., and occupied a water area of 25 acres. It is, however, as a rule, considered not to be a profitable business to raft such a quantity of timber in one mass, as rafts beyond 3,000,000ft. or 4,000,000ft. become very cumbersome. The United States are great consumers of Canadian pine, and such being the case the log traffic across Lakes Huron and Superior is very considerable. The transport of sawn timber, or "lumber," is carried on by boats specially constructed for conveying large quantities; but the logs themselves are merely towed across the lakes, after having been made up into rafts, as explained. This importation of foreign wood by America is not due entirely to there not being enough home grown timber to satisfy the demand, but it is in a great measure owing to the fact that a great proportion of the pine growing districts in Michigan is in the hands of a few wealthy men, who, knowing that the value of timber must increase yearly as the supply diminishes, are in no hurry to dispose of them except at their own prices, and consequently lumbermen are driven into seeking their timber in Canada, notwithstanding the extra cost of transport, &c. The result is that a great many of the Ontario timber limits are being run by Americans. A good instance of this is that of the Saginaw Salt and Timber Company, whose saw mills are in Michigan, U.S.A., while their timber is derived from three large tracts of forest land situated not far from Lake Wannapitae, in Canada. The logs have to be driven down two rivers into the Georgian Bars, and then rafted across Lake Huron, a distance in all of close on 350 miles. Stormy weather during transit over the lakes is by no means uncommon, and the effect of a high sea on a huge timber raft is very remarkable. The outside logs only get tossed about by the waves to any extent, and they form such an efficient breakwater to the rest of the raft that 50ft. from the edge the swell is scarcely felt. The centre of this floating island is perfectly quiet, and to leeward the logs are as free from motion as if they were in a river.

We have now followed the course of the timber from the forest to the saw mills, and have seen it pass through a good many hands during its journey by sleigh, river, and lake; but these articles would hardly be complete were they to be closed without some reference to the saw mills themselves, since the latter play so important a part in the timber industry. Being both constructed and worked in a different way to what is usual in England, a brief outline of their *modus operandi* will probably be of interest. The saw mills in Michigan and Ontario bear a striking resemblance to each other, which is not surprising considering the proximity of the two places, and the constant interchanging of ideas arising from the business transactions, which bring a great many men from one country to the other. Consequently Fig. 9, which is in reality taken from a Saginaw saw mill, is typical of the ordinary saw mill of either Canada or America. The situation chosen for the erection of a mill is usually on the water's edge, at a spot where the logs can be floated right up to the foot of the incline shown on the right hand side of the illustration. Up this incline they are conveyed by means of an endless chain furnished with projecting dogs at suitable intervals along its upper surface. The lower part of this chain works below the water level, so that a man with a pike pole can readily guide the logs within range of the dogs, which take them up on to the mill floor.

The sawing machines are always placed on the first floor, and this is a very practical arrangement, for several reasons. Firstly, it is a great safeguard against injury from floods; secondly, it permits of the shafting being placed below the mill floor, which keeps the belts out of the way, leaving more space between the machines; thirdly, it enables the men whose duty it is to look after the shafting, to do so without danger to themselves, as they have plenty of room to move about, and can see what they are doing when approaching a revolving shaft for lubricating the bearings, or putting on a belt. This last point is one the importance of which is too often under-rated in England, where accidents frequently occur, owing to the shafting being fixed in narrow and obscure pits, only just large enough for the pulleys to revolve in, which obliges the men to climb in between running belts, a highly dangerous proceeding, especially if the light is imperfect. In North American mills everything is sacrified to quantity, whilst quality of work and waste of wood are but secondary considerations. A few years ago waste of wood was hardly considered at all, as will be readily understood from the fact that the rack bench was the only saw machine used, even for planking. However, since the price of wood has gone up, the band saw is replacing the rack bench in cases where a number of cuts are required in a log. The saving effected by this change can be realised by the following figures: The saw cut (or "kerf") of a circular saw, as used in rack benches, is $\frac{5}{16}$in., and of a band saw blade $\frac{1}{8}$in.; so that by the use of the latter a saving of $\frac{3}{16}$in. per cut is effected. This would show, in the case of a log in which twelve cuts were taken, no less an economy than 2$\frac{1}{4}$in. of wood.

In American mills nearly all the shifting of the timber is done by mechanical appliances, a system which obviates a great deal of hand labour, and which might be used to advantage also in England. The sawn lumber is passed out of the mill on trucks, and the refuse is shot down the diagonal shoots shown in the illustration. The lower extremities of these shoots are at a sufficient height to allow of carts being drawn up under them. In the whole of Canada there are between five and six thousand saw mills, employing collectively about forty-five thousand men, and the value of their annual output is stated to be very nearly £8,000,000. Many of the mills are working only six months of the year. The total number of factories in Canada dependent on the timber industry—that is to say, turning out wood, or articles made from it—may probably be put at twenty thousand, and the number of hands employed in them amounts to at least one hundred thousand.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 31st January, 1888.

The Iron Market.—The business of the iron market grows steadily. The revival evidently is not due to transient influences, and there is a constant development in progress, proceeding from a gradually increasing consumption. There is an expanding tendency, too, in the export trade, clearly shown in the Customs returns for the month of December. Thus the improvement is likely to continue. The Paris merchants persevere in the attitude which they assumed at the end of the last year relatively to the manufacturers of the North, whose movements they now follow closely. During the last week a fair amount of business has been transacted at firm prices. The abolition of the traffic in *acquits-à-caution*, that is, permits to temporarily import pig iron duty free, has given satisfaction to the manufacturers of the North and North-East, and stimulated business in that locality; but it has occasioned something like consternation in the centre and South, where manufacturers are henceforth deprived of the advantage afforded by the system of temporary admission. The necessary consequence will be to direct the foreign business to the Northern districts. An effect of this change is already to be seen in the blowing in of more blast furnaces in the Meurthe-et-Moselle. Prices of pig iron in the latter departments are steadily rising. The value of the exports of iron and steel of all sorts in the year 1887 amounted to £689,920, against £304,400 in the previous year.

State of Trade.—The Customs returns for the last month of 1887 show a marked revival in our foreign trade. Relatively to December of 1886, exports have largely increased. The expansion is especially noticeable in manufactured goods, showing a revival in the home industries. This greater activity has naturally rendered necessary larger purchases of raw materials, and accordingly we find a notable increase in the imports of such commodities. The railway accounts for the last year also reveal a better state of trade. The Lyons railway has gained in receipts, relatively to the preceding year, 2·37 per cent.; the Northern line has gained 2·06 per cent.; the Western 0·30 per cent.; and the Midi 0·75 per cent. The Eastern and the Orleans show a small deficit.

Alcohol Manufacturing Company.—An important industrial affair has just been brought to a satisfactory issue. M. Philippart, well known for his achievements in company promoting, obtained control of the patents granted to MM. Bang & Ruffin for the rectification of alcohol; but falling out with the patentees, he took the matter into the Law Courts. But time brought wisdom, and the litigants arranged their affairs outside. The result was that these valuable patents were sold to the firm of Dansaert & Loewenstein, of Brussels and Paris. The latter have now transferred their rights to a company founded for the purpose, and called the Société Universelle de la Fabrication des Alcools Chimiquement Purs. This will be the parent company, from which we may expect a numerous offspring; the first, to be launched in a few days, will be called the Société Française pour la Fabrication de l'Alcool. The capital for these companies, in each case 3,000,000fr., has, it is said, been already subscribed. As soon as the French companies are fairly afloat, the Société Universelle, which, by the way, is controlled by the Comptoir Industriel, founded last year by M. Philippart, will give its attention to the foreign patents, of which the German and the English are likely to be the first dealt with.

BERLIN, 30th January, 1888.

The Iron Market.—Up to the present time Government has not taken any decided position either for or against the various syndicates in the iron trade; but owing to the latest action of the Blast Furnace Owners' Union, which determined to boycott all those merchants who do not conform to their rules, it is quite possible that the intervention of the State will be invoked by the merchants and by others interested, so that the irksome restrictions which the syndicates endeavour to place upon the home trade may be removed. If the opposition party are successful in this matter, it is quite possible that the whole artificial fabric of syndicates may tumble to pieces. Up to the present the market remains exceedingly firm. Blast furnaces and rolling mills in the Silesian district are overwhelmed with orders, and stocks are constantly diminishing. The demand for sheets has also risen to such an extent that quick delivery cannot be guaranteed. Considerable impetus has been given to the wire trade by the formation of a syndicate of wire nail makers, to which I referred two weeks ago, and the production of most wire works is already sold up to the end of the current quarter.

Importation of Petroleum in Bulk.—German importers of petroleum are devoting increased attention to the employment of tank waggons and tank vessels. Messrs. W. A. Riedemann & Co., of Geestemünde, and Messrs. N. Schutte & Son, of Bremen, have given an order to Messrs. Armstrong, Mitchell, & Co., of Newcastle, for a new tank steamer to carry 4000 tons of petroleum. The steamer is to be delivered by the 1st September next. With this addition the two firms will own five tank steamers and one tank sailing vessel.

The Chemical Industry.—The general management of Count Guido Henckel von Donnersmarck's chemical works in Neudeck, Upper Silesia, propose to erect in connection with their ovens for the roasting of zinc-blende a factory for the working up of calcination gases into liquid sulphurous and sulphuric acid. It is hoped that by this process the calcination gases will be completely freed from sulphur, and will then have no injurious effect upon the neighbouring vegetation: whilst the value of the acid produced will cover the working expenses. A chimney 190ft. high is now being built to discharge the purified calcination gases.

Lubricants.—Messrs. Born Brothers, of Ilversgehofen, near Erfurt, are introducing a kind of mustard oil which has been found to be exceedingly suitable for lubricating purposes, and which may be used to advantage where no other lubricator can prevent the heating of bearings. It has proved especially suitable in those cases where either speed or pressure is great, as for instance in turbines, rolling and crushing mills. The new lubricant has recently been tested at the Machinenfabrik Geislingen on the testing machine of Messrs. W. H. Bailey & Co., of Salford, when for purposes of comparison tests were also made with the best olive oil, and a mixture of olive oil and mineral oil. The results obtained showed that compared with olive oil the lubricating value of mustard oil is as 263 to 168, and as compared with a mixture of olive and mineral oil the lubricating value is as 263 to 125. A further advantage of mustard oil is its low freezing point. This oil solidifies at a temperature of from 7°C. to 8°C. below zero, so that even in cold weather it still retains its lubricating value, while olive oil, as is known, solidifies at a temperature slightly above zero.

The Spirit Industry.—Since the Excise duty on spirits came into operation, business in the better qualities of spirits has considerably declined. Previous to its imposition, both retailers and large householders bought largely in anticipation of the increase of duty, and consequently business during the last quarter of the year, when it is generally pretty brisk, is this year very quiet. The consumption of the ordinary class of spirits has also decreased. A tax of 20 per cent. is now imposed on methylated spirit, but notwithstanding its moderate price the consumption remains low.

VIENNA, 30th January, 1888.

The Coal Market.—With the exception of some lines in Eastern Galicia, traffic has again become regular on all the Austrian railway lines, and the coal trade is very brisk. This is partly owing to a good demand for household coal, but chiefly to the arrears accumulated during the interruption of traffic, which lasted for nearly a month.

The Iron Market.—The spring trade is developing very slowly indeed, and in many centres which are usually animated at this season of the year, no transactions of importance have taken place during the week. Notwithstanding this dulness in the general trade, prices are maintained without difficulty; and the organisation of the iron masters' syndicate, which I reported in my previous letters, has given an unusual firmness to the Austrian iron market. Engineering works and foundries in Bohemia are well supplied with orders, but in Hungary there is scarcity of work. The makers of such tools as spades, picks, and shovels specially complain of insufficient orders. Under these circumstances the action of the Hungarian Government in dismissing the board of management of the State iron works, which I reported in a previous letter, appears fully justified. What little business there is done in these works is now superintended by two civil servants of the Minister of Finance; but the Government has some difficulty in obtaining offers from private firms for taking over the works. Iron masters in Austria contend that the rent stipulated by Government could only be paid if the quantity of iron produced and sold at these works were in excess of last year's returns; but as there does not seem much prospect of trade reviving to any large extent, these works will probably remain idle. At the principal works in Vaida Hunyad enormous stocks of pig iron have accumulated during last year, and the Government have sent down a commission of experts to report on the best way of utilising these stocks. The commission are of opinion that the crude iron would be eminently suitable for the manufacture of Bessemer steel, and the Government, acting on their advice, have transferred 100,000 tons of this pig iron to the Dyosgyor works, to be converted into steel rails for the State railways.

The Hungarian Small Arms Factory.—The first general meeting of the shareholders in this enterprise took place last week. According to the statutes, the total capital amounts to £240,000, divided into 30,000 fully paid up shares. The company has been formed for the manufacture of rifles and ammunition, and negotiations have already begun with the Hungarian Government for the supply of 180,000 rifles and a corresponding quantity of ammunition.

Portable Electric Light Plant.—Since you recently published particulars of the portable electric lighting plant made by Messrs. Siemens & Halske for the North-Western Railway of Austria, it may perhaps interest your readers to learn what has been done in Hungary in the same direction by Messrs. Ganz & Co., of Buda-Pesth. Their electric light plant has been tried in various parts of the country, having been transported in all over a distance of 1600 miles without any breakdown. The general arrangement is very similar to that of the plant illustrated by you, but in the details the two differ. Messrs. Ganz & Co. employ an alternating current dynamo, and put all the eight arc lamps in series. For incandescent lighting they employ a small transformer. Power is supplied by an 8 h.p. portable engine working at 60lb. pressure, and making 130 revolutions per minute. On a platform projecting back over the fire box, and therefore over the driver, is mounted an alternating current machine, driven direct from the fly wheel at 750 revolutions per minute. The engine and dynamo are protected by a roof against the weather. The car contains eight alternate current arc lamps, suspended from flexible bars so as to protect them against jolting on the road; also a small four-wheel trolly, on which are mounted two drums containing a mile and a quarter of suitable wire; also two water butts, insulators, earth anchors, a screw jack, and an assortment of tools. The lamp posts are of wood, and fixed on brackets fixed to the outside of the car. The total cost of the plant was about £830. All the circuits are carried overhead, and at a recent trial one superintending engineer, one driver, one lineman, and eight labourers erected the plant and began lighting up in seven hours, reckoned from the time when the engine and car were unloaded from the railway trucks. After finishing work the whole of the material was again replaced, and the engine and car loaded in four and a half hours.

Safety in Mines.—Some time ago the owners of the Ostrau-Karwin coal mines offered a prize of one thousand ducats (about £500) for the best method of rendering shots in fiery mines safe, or for substituting some other method of breaking down coal for shot firing. None of the proposals were considered to be sufficiently meritorious to obtain the prize; but as two of them were yet of considerable utility, an award has been given to these, Lieutenant-Colonel Lauer obtaining 300 ducats for a special fuse, and Herr Walcher 150 ducats for his mechanical coal breaker, which was illustrated in *Industries*, Vol. I., page 372.

BRUSSELS, 31st January, 1888.

The Coal Market.—The situation of the market continues firm, and with the exception of household coal, the tendency of prices is to advance. Steam coal, coal for metallurgical purposes, and nuts have risen. Important contracts for coke have been made up to the end of June at 10s. 9d., but no business is being done for the third quarter of the year. Dross is exceedingly scarce. Unscreened coal is quoted at 8s. 5d. to 10s., cobbles at 13s. 7d. to 15s. 2d., and small coal at 5s. to 6s. 2d. Several collieries which could work seams of coking coal decline to do so, as they consider that the price at present obtainable would not be remunerative. The Sambre coke furnaces have been rented and re-lighted.

The Metal Market.—Although more blast furnaces have been re-lighted, the price of pig iron has not been affected. Other metals, however, are fluctuating. Rolling mills are somewhat less busy, but there is a good demand for sheets; and girders are also in request. The State railways will shortly contract for 2000 trucks and thirty to a hundred passenger coaches. Fifty locomotives will also be ordered, and there is some talk of forty being required for the economic railways. Ten third class carriages for the new train-tramways have been ordered, which will be ready by May. This order has been obtained by the Société des Ateliers de Malines at £1,878, as well as one for fifteen small baggage vans at £1,860. The firms of Veuve Frédérix, of Liège, and the Dyle-Bacalan Company have received commissions for bridge work for the Dutch colonies, and the Malerie Works for mail vans for the Italian railways. During this week tenders will be opened by the State railways for 167 passenger coaches, 287 trucks, and thirty-nine baggage vans. There is therefore good business for our works in prospect. The erection of iron buildings is making much headway, and the Société des Forges d'Aisneau are making a specialty of this branch. M. Villut and the representative of the Biesme works are putting up a number of iron buildings for the Brussels Exhibition. The whole of the material for a railway, about fifteen miles long, to be laid from the Caspian Sea to Amal, has been ordered from the Cockerill Company, who will also supply the locomotives and trucks. The gauge of the line is 4ft. 8½in. The rails are to weigh 47lb. per yard, the total weight of rails required being about 1200 tons. The Committee on the Metal and Coal Exchange consists of Messrs. Herpegnies, managers of the Jeneppe collieries; Ch. Semal, manager of the Montigny-sur-Sambre colliery; M. Delaive, of the Louvière works; A. Roubert, A. Passelecq, and E. Kelecom. M. Valère Mabille, the president, is not eligible for re-election, and a meeting will shortly be held to elect his successor.

Glass Works.—Although the prices of all kinds of glass have been reduced, very few orders are received; but the demand is always small at this season.

The Lighting of the Exhibition.—The executive committee are making arrangements for the division of the lighting of the Exhibition, the total light required being about 600,000 c.p., distributed among 1200 glow lamps and 350 arc lamps. English and Belgian electricians are taking the principal part, French and German firms being less prominently represented. The motive power is supplied free, 500 h.p. being available for the buildings and 500 h.p. for the gardens. For the illuminated fountains, there will be a separate installation, with 100 h.p. M. Pieper, with Mr. Sennett, will take up this section. The Thomson-Houston, Edison, and Bernstein companies, M. Bouckaert, and M. Dulait will undertake portions of the

Digitized by Google

lighting, for which very advantageous offers have been received. Paris and Brussels firms have undertaken the gas lighting on almost gratuitous terms.

THEATRE LIGHTING BY ELECTRICITY.—The Molière Theatre at Ixelles, a suburb of Brussels, is entirely lighted by electricity, small glow lamps being used in the auditorium, on the stage, and in the rooms, and an arc lamp being placed in the chandelier. The atmosphere of the house has been much improved since gas was done away with. The price charged for the electric light is the same as was previously paid for gas. The generating plant is placed in the basement at the back of the theatre, a 35 h.p. Meunig engine and two Thomson-Houston dynamos being employed. Steam is supplied from a De Naeyer boiler.

HELIOGRAPHY.—During trials with an ordinary heliograph made by the special army corps, some difficulty was experienced in interpreting the signals. It was found that the bright image of the luminous point was, with some individuals, prolonged on the retina, causing them to confuse dots and dashes. To overcome this difficulty an improvement has recently been tried by which the distinction is not made by the time of the flash, but by its colour, red being used for the dashes and green for the dots. The trials were made at Mont-sur-Marchienne over a distance of 1¼ miles, when inexperienced operators were able to send three twenty-word messages in twenty-eight minutes. When the heliograph was worked by expert Morse telegraph operators the same messages were sent in eight minutes.

DÜSSELDORF, 30TH JANUARY, 1888.

THE IRON MARKET.—We have had another busy week in iron. Judging from their eagerness to transact business, buyers appear to have still unshaken confidence in the near future. The demand for crude iron is a remarkable feature of the present time. In spite of high prices and a consequently failing export trade, it tends to increase rather than diminish. Some of the blast furnace owners have sold the whole of their make until the end of May, and all have their order books well filled. The demand for forge pig has this week been so great that prices have further advanced, Rhenish-Westphalian white forge being now quoted at 52s., and Luxemburg forge at 49s. to 50s. Spiegel pig, for which a brisk foreign demand has sprung up, has advanced by leaps and bounds. It is hard to ascertain the price at the present moment; but it is about 58s. for the 10 to 12 per cent. quality. This sensitiveness of the market is in part due to the reported purchase, by a large share company established for the purpose, of all the limestone quarries from which the blast furnaces are supplied. An event of this sort cannot but have a pernicious effect upon the iron industry, which seems to be destined to be controlled by "rings." The markets for finished iron have followed those for crude. Bars are in better demand for home consumption. All manufacturers are sufficiently provided with work for the first quarter of the year, and some have booked orders much farther forward. There is, however, much complaining concerning the prices, the advance in those of the raw material having seriously diminished the margin for profits. It is certain that a further rise must shortly be declared all round; that in boiler plate is expected to be as great as 20 per cent. The business in common plates steadily increases. Wire is now the cheapest class of goods. The rail market has been stimulated by a victory gained over the English makers in Chili, where a contract for 7500 tons has been secured for the Rhenish-Westphalian works.

THE PRODUCTION OF CRUDE IRON IN 1887.—The make of pig iron in Germany, including Luxemburg, in the month of December amounted to 359,867 tons. This brings the total for the year 1887 up to 3,907,364 tons, an increase of 17 per cent. on that of 1886, and 4·15 per cent. on that of 1885, which was the highest ever previously reached. The make of the first quarter of the year, consisting of ninety days, amounted to 880,318 tons; that of the second quarter, of ninety-one days, to 962,663 tons; that of the third quarter, of ninety-two days, 1,011,010 tons; and that of the last quarter, of ninety-two days, 1,057,873 tons. Hence it will be seen that the daily make rose from 9781 tons in the first quarter, to 11,499 tons in the last quarter of 1887, an increase of 17·6 per cent. In view of the present large production of crude iron and the blowing in of fresh furnaces, it is hard, despite the heavy demand which now characterises the markets, to avoid the conclusion to which these figures seem to point, that we must soon reach a stage where production will begin to exceed consumption. Of the quantity manufactured last year 48·7 per cent. was forge and spiegel pig, 11·1 per cent. Bessemer pig, 27·5 per cent. Thomas pig, and 12·6 per cent. foundry pig.

CANAL EXTENSION.—Vigorous and persistent efforts have for several years past been made, chiefly on the part of colliery owners and iron masters, to obtain an extension of the canal system. It is generally perceived that the future development of the staple industries of Germany depends largely upon the cost of transport, and as water carriage is still the cheapest available, it seems desirable to increase the navigable ways. The subject was earnestly discussed at a recent meeting of the Miners' Association at Dortmund, where it was announced that the project for connecting Ems with Dortmund was making steady progress towards realisation. Dr. Natorp directed attention to the movement in progress in France for the further development of the waterways, and showed that in five years, from 1881 to 1886, the traffic on the existing canals had increased from 15,000,000 tons to 23,900,000 tons, or fully 53 per cent.

THE PETROLEUM TRADE.—An attempt to syndicate the petroleum trade has proved abortive. Prices have risen notwithstanding, though not in the degree contemplated by the speculators, who thought to corner this commodity. A change is being effected in the mode of dealing with American petroleum in this locality. At Rotterdam, the port of delivery, two large iron reservoirs are in course of construction of sufficient capacity to hold 1,250,000 gallons, or about 30,000 casks. The oil will be brought from the United States in tank vessels, and discharged into these reservoirs, from which it will be pumped into casks and transported by river boats to this district. The same casks will be used over and over till they become unsound. The system will put an end to the importation of American casks, a matter of considerable importance to the coopering industry, which here is of some magnitude.

LILLE, 31ST JANUARY, 1888.

TEXTILE MANUFACTURES.—The last two weeks have been marked by activity in the linen goods trade. Our markets have been visited by buyers from Paris and the West, who have dealt largely, but who cannot be said to have purchased freely; since they have sought to depress prices, and have, in most cases, driven hard bargains with the manufacturers. The latter have with difficulty obtained a small advance for goods woven wholly or partly of jute yarn. The present activity seems likely to last for at least a few weeks. The establishment of a wool market at Havre and Antwerp has induced the principal merchants of Roubaix-Tourcoing to provide a similar market for that wool manufacturing centre. Steps have been taken in conjunction with some of the first banking houses of Roubaix to carry the project into effect as speedily as possible. The matter is in the hands of a commission of twelve members, of whom six are merchants of Roubaix and six merchants of Tourcoing, all men of great influence. The woollen goods trade is growing more animated. For "fancy" goods, the season promises to be very satisfactory. Judging from present indications, we are approaching a period of general activity. For Rouen cotton goods there is also a fair prospect. Manufacturers regard the future more hopefully, and the tone of affairs throughout is decidedly stronger.

FLAX AND YARN MARKET.—The demand for home grown flax is still strong. Walloon is specially inquired after. A large quantity of produce has changed hands this week at full prices. In some cases there has been a slight movement in favour of sellers. Russian has been bought in large quantity for future delivery. Prices are very firm. There is nothing new to report concerning yarns; the demand continues active, and spinners are easily able to maintain the recent advance. Jute yarns command a ready sale at full prices. During the week 52 tons of linen yarns and 19 tons of jute yarns were shipped from Dunkirk to Leith. The market here, both for raw flax and for yarns, has been favourably influenced by reports of activity in the market at Ghent.

THE IRON MARKET.—The iron market remains unchanged in its general features. The tone of business is strong. A further advance in prices being expected, both consumers and merchants are buying freely. The decision come to at the beginning of the week, to abolish the traffic in *acquits-à-caution*, has occasioned much rejoicing among manufacturers of this and the South-Eastern department. An immediate result will be the blowing in of four blast furnaces in the Meurthe-et-Moselle.

MARGARINE.—At a meeting of the Société des Agriculture du Nord, held last week, it was stated by one of the speakers that not less than 33,000lb. of "margarine butter," containing from 80 to 90 per cent of margarine, are brought every week into Lille. This is sold as butter from our best dairies. It would be interesting to know how much of "best French butter" manufactured in this way is exported.

MADRID, 30TH JANUARY, 1888.

PIG IRON.—The three makers of pig iron at Bilbao have for some time worked under an agreement as to prices, by means of which they were enabled in their home sales to obtain the full benefit of the high duties charged on pig iron imports. These firms have been selling foundry pig in the home market at 56s. per ton, and forge pig at 52s. per ton. Owing to some misunderstanding, this syndicate has now been broken up, and Spanish consumers will, in consequence, obtain their supplies in future at lower rates. The excess of the production of pig iron over the home consumption is at present about 120,000 tons per annum.

THE PYRITES FUMES.—Although the general question regarding the fume nuisance has not been settled, a decision has been come to by the Home Minister in the case of the Calanas mine. The municipal authority, on the plea of sanitary requirements, prohibited the burning of pyrites in the open air, but the governor of the province thought himself authorised to suspend the order until a decision was arrived at by the Central Government. The Minister has now decided that the governor had no right to reverse the order of the municipality of Calanas. It is very difficult to say what will come next, because there is a very warm controversy over the various points of the question, both on legal, economical, and technical grounds. To my knowledge the fact is that the open air burning is not necessary, nor even convenient, and that the improved method of roasting, as adopted at the Cuchichon mine and at St. Domingo, can be equally employed by Rio Tinto, Tharsis, and the other works with great advantage. A foreign engineer has assured me that copper can be produced £5 per ton cheaper without the open air burning of the pyrites.

QUICKSILVER.—The Almaden mines produced last year 53,109 flasks of quicksilver. This quantity could have been very easily increased to 60,000 or more; but either the Government, or the London agents under the contract of the loan extending to 1900, have the idea that the output ought to be kept low, so as to increase the price. Last year's statistics show that a larger profit can be made out of 53,000 flasks at present prices, than out of 80,000 at the rate prevailing at the commencement of 1887.

NEW YORK, 21ST JANUARY, 1888.

THE METAL MARKET.—There has been but little change in the condition of the market since the beginning of the month. Merchant iron is but little sought after, but there is a good demand for plate and tank iron and steel. Tin is not much in request, lead is steady, and copper has dropped during the past week. There were in blast on January 1st 341 furnaces having a weekly output of 140,690 tons, and out of blast 246 furnaces capable of an output of 61,020 tons; at the same date last year there were 332 furnaces in blast with an output of 127,660 tons. The building of cars during the past year has been active, and prospects are good for continued prosperity in this line. The Missouri Car and Foundry Company did business to the extent of £550,000 in 1887, and are now working at their full capacity, turning out twenty-five cars a day, and having orders ahead for 1000 cars. The wire cables in use on the Chicago street railways are being made by the John A. Roebling's Sons Company, of Trenton, New Jersey. They are of cast steel wire, having an outside diameter of 1¼in., and guaranteed to stand 194,000lb. per square inch. The strike of the miners and railroad men has not yet been adjusted, and the price of fuel will advance if the strike continues. As many of our manufacturers are dependent on the Reading companies for their supply of fuel, the prices of pig iron must advance or the cost of production must be lowered, neither of which seems possible at present, for an increase of price will open the market to competition from other sources.

STEEL RAIL PRODUCTION.—The production of steel rails by our Bessemer steel works during last year amounted to 2,049,638 gross tons, an increase of 487,228 tons over the previous year. The New Year, however, does not open very auspiciously, as many large orders are still withheld, and the works which closed down in December continue idle.

THE CALUMET AND HECLA MINE.—The copper produced from this mine during last month was 1503 tons, making a total for 1887 of 31,373 tons, against 30,700 in the previous year. Part of the mine was closed owing to fire from August 4th to September 12th, and from November 20th up till now. The present output is all from the South Hecla location.

PHILADELPHIA, 21ST JANUARY, 1888.

COPPER.—A petition is being circulated for signature by manufacturers who use copper, asking Congress to remove the 4 per cent. duty on copper. It states that there are over 10,000,000lb. of ingot copper used in the United States per year, that the home supply exceeds the demand, and that the present duty is not needed to protect home production, but simply benefits speculators, allowing them to export copper at a less price than is demanded for home consumption. It is probable that the petition, which is being extensively signed, will result in the removal of the duty.

THE USE OF STEEL FOR STREET PAVING.—A new pavement for use in streets subjected to heavy traffic is being laid in Chicago. It consists of steel rails, each 16ft. long, having corrugations on the top, laid a few inches apart, with a patent composition between. The first order for 50 tons of these rails has just been completed.

THE COST OF GAS AND ELECTRIC LIGHTING.—The following figures are taken from a report made by Professor Barret to the City Council of Chicago on the relative cost of lighting the city by gas and electricity. The cost of maintenance, interest, deterioration, repairs, and all other charges which can be properly placed against the systems of lighting have been taken into account in estimating the cost:—

	Number of lights.	Candle power.	Cost per year.
Gas	3,273	52,368	£12,351
Incandescent lights	3,273	98,190	£9,346
Arc lights	750	1,500,000	£7,180

THE PROGRESS OF THE SOUTH.—The last year has seen wonderful mechanical progress throughout the South. In Georgia, Alabama, Tennessee, and Kentucky furnaces and manufactories of all kinds are being erected, and cities are being built. In the city of Birmingham alone, which had at the beginning of 1887 ten blast furnaces, with a total daily output of 850 tons of pig iron, there have been erected fourteen new furnaces. When all are in blast the total daily output will reach 2000 tons.

HEATING BY PETROLEUM.—The Bethlehem Iron Company have been experimenting for some time on the use of petroleum. The apparatus used is what is known as the Archer gas fuel process. Their experiments were made with two ingot re-heating furnaces, and were so successful that two additional plants have been contracted for, and are now in course of erection.

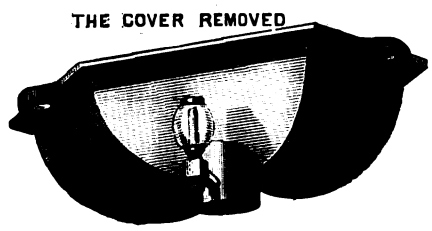
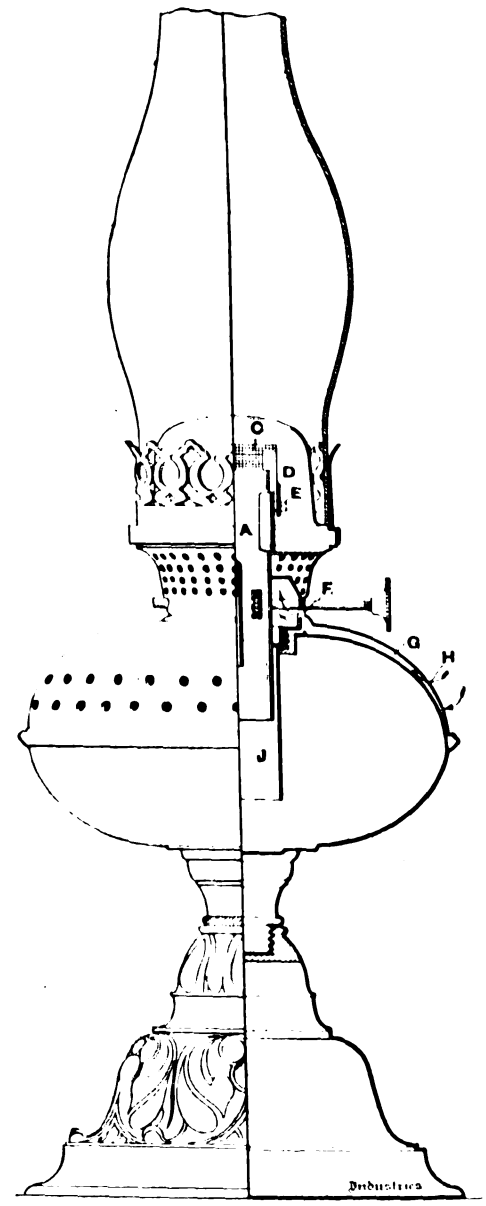
DALETT'S BOILER SHELL DRILL.



ALMOND'S COUPLING.

ATTEMPTS have from time to time been made to substitute some other gear for the usual bevel wheels employed to communicate motion between two shafts crossing each other at an angle. At the Inventions Exhibition a very ingenious gear was exhibited, in which two right angle

THE COVER REMOVED



shafts terminated with perforated discs, the latter being connected by a set of steel rods joined at right angles to each other, and sliding in and out of the holes as these come nearer and further from each other whilst the shafts rotated. Another type of angle gear is illustrated in the above engraving. It is the invention of Mr. Almond, an American engineer, and is now being introduced into this country by Messrs. Clark & Wellington, of 73, Queen Victoria-street, London. Motion is supplied to the coupling and taken off from it by two belts running in planes at right angles to each other. The coupling consists of a cast iron box secured to an overhead beam, and containing two bearings with special lubricating arrangements. A short length of shaft is laid through each bearing, carrying outside the pulley and inside a peculiar crank resembling somewhat a toggle joint. In the centre of the casing is fixed a steel stud, the lower end of which is secured in the centre of the cover shown removed in our illustration. Upon the stud slides a sleeve, having two cross arms at right angles to each other, in which slide steel pins, each terminating in a ball. This ball engages in a socket at the extremity of each toggle crank, and as one wheel is revolved this crank imparts an oscillatory motion to the sleeve on the central pin, at the same time carrying it up and down. This motion is transmitted by means of the other arm and ball and socket joint to the crank of the other pulley. As far as can be judged from an inspection of this coupling, and from turning it by hand, motion is transmitted very evenly and silently, there being no backlash or dead point in this gear. The gear is lubricated by pouring oil into the box, and as the cranks revolve they dip into the oil and gradually distribute it over the whole of the working parts. The oil can be drawn off from time to time by a gun metal plug, to which is attached a glass vessel showing the amount of oil contained in the casing. These couplings are at present made in three sizes, viz., for 1¼in. shafting to run at five hundred revolutions per minute, the pulleys being 12in. diam. by 4in. wide; for 1½in. shafting to run at three hundred revolutions per minute, with pulleys 16in. by 6in.; and for 1 $\frac{15}{16}$in. shafting to run at 250 revolutions, with pulleys 20in. by 9in.

DALETT'S BOILER SHELL DRILL.

WE are indebted to our contemporary, the *American Machinist*, for the accompanying illustration, showing a boiler shell drilling machine, designed and constructed by H. Dalett & Co., Philadelphia, Pa. These machines are used for drilling rivet holes, stay bolt holes, &c., in boiler shells. The improvement claimed on the old design is that the plates may be drilled after they are bent and put in place, so that there is but one handling of both plates in laying out as well as in drilling. The machines are made of two types, the "A" style consisting of a turntable on which the boiler shell is set on end, and around which three or more uprights carrying horizontal drilling heads are arranged. A novel and effective arrangement for driving the portable drills has been provided. In the "B" type, as shown in our illustration, the boiler shell rests on four or six rollers, on which it freely turns. The drilling heads, provided with the same driving apparatus as in the "A" type, rest on horizontal beams, these in turn being supported at both ends by strong uprights. The weight of the beams and heads is counterbalanced, so that the whole can be readily lowered or raised. The heads are moved horizontally by means of a pinion gearing into a rack on the lower beam, while the vertical adjustment is effected by a screw. Care has been taken to design the head in such a way that the operator, standing on either side, has full command over both crank handles, which materially assists in quickly setting the drill. The machine is adapted for drilling all sizes and kinds of boiler shells, including those for large marine and small stationary boilers, and can be built of any length and with any number of heads.

THE "VICTORIA" SAFETY LAMP.

THE accompanying illustrations show a new safety lamp invented by Mr. E. Sherring, of 39, Hanging Ditch, Manchester, and intended for burning either petroleum or paraffin. The inventor claims for this lamp that it prevents the disastrous results accompanying the upsetting of ordinary lamps. The novel features claimed for the

lamp are the following: An air chamber G is placed as a jacket over the oil reservoir, thereby preventing the oil from becoming over-heated and producing an explosive mixture. The air supplied to the flame enters through the perforations H, passes along G, and reaches the flame through the perforations at F. In this arrangement the air gets heated before it comes in contact with the flame, and is therefore in a better condition for giving economical light than in the case of the ordinary lamp. In case of the lamp getting upset, the extinguishers C D, which are pivoted at E (Fig. 3) at each end of the wick tube A, automatically close over the wick, as shown in Fig. 1, and instantly extinguish the flame. A cylinder or tube J is placed in the orifice of the oil reservoir, which is constructed on the well known principle of the safety ink bottle, and prevents waste of oil when the lamp is

Digitized by Google

thrown over, as the oil runs behind the cylinder instead of escaping through the wick tube. This wick tube A is elongated, so as to prevent the ignited or smouldering wick from being turned downwards into the oil reservoir

FIG. 1.

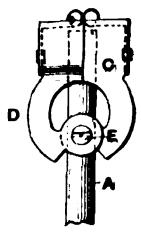


FIG. 2.

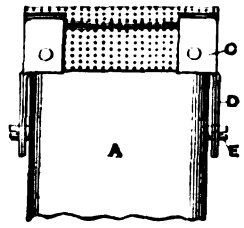

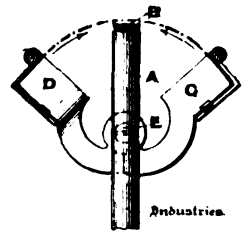

FIG. 3

and probably cause an explosion. The oil reservoir and all the fittings are made of metal, so that breakage is scarcely likely to occur. The lamp, as will be seen from the illustration, is artistically designed, and the details are well thought out.

Notices of Meetings.

THIS WEEK.

INSTITUTION OF MECHANICAL ENGINEERS.—Friday, 3rd February, 7-30 p.m. Continuation of forty-first annual general meeting, commenced on Thursday, 2nd February, for which the following business was set down: Annual report of Council and election of office bearers, and resumed discussion on "Irrigating Machinery on the Pacific Coast," by Mr. John Richards. The following papers to be read and discussed as far as time permits: "On the Position and Prospects of Electricity as Applied to Engineering," by Mr. William Geipel; and "Third Report of the Research Committee on Friction: Experiments on the Friction of a Collar Bearing."

ARCHITECTURAL ASSOCIATION.—Friday, 3rd February, 7-30 p.m. Ordinary meeting. Paper to be read by Mr. R. P. Spiers.

GEOLOGISTS' ASSOCIATION.—Friday, 3rd February, 7-30 p.m. Annual general meeting, after which a paper will be read "On the History and Work of the International Geological Congress," by Mr. W. Topley, F.G.S., Assoc.Inst.C.E.

ROYAL INSTITUTION OF GREAT BRITAIN.—Friday, 3rd February, 9 p.m. Lecture on "Ancient Microscopes," by Mr. Frank Crisp.—Saturday, 4th February, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

UNITED SERVICE INSTITUTE.—Friday, 3rd February, 3 p.m. Paper to be read on "Speed as a Factor in Naval Warfare," by Admiral the Hon. E. R. Fremantle.

JUNIOR ENGINEERING SOCIETY.—Friday, 3rd February, 7-45 p.m. Paper to be read on "Some Novel Mechanisms," by Mr. W. J. Tennant.

NEXT WEEK.

CLEVELAND INSTITUTION OF ENGINEERS.—Monday, 6th February, 7-30 p.m. Paper to be read on "The Working of the New Patent Law," by Mr G. J. Clarkson, F.I.P.A.

SOCIETY OF ENGINEERS.—Monday, 6th February, 7-30 p.m. Presentation of premiums. Inaugural presidential address by Mr. Arthur T. Walmisley.

SOCIETY OF ARTS.—Monday, 6th February, 8 p.m. Cantor lecture on "Yeast, its Morphology and Culture," by Mr. A. Gordon Salamon, F.I.C., F.C.S.—Tuesday, 7th February, 8 p.m. Foreign and Colonial Section. Paper to be read on "British Columbia," by Mr. Henry Coppinger Beeton, Agent-General for British Columbia.—Wednesday, 8th February, 8 p.m. Ordinary meeting. Paper to be read on "The Continuation of Elementary Education," by Mr. W. A. Lant Carpenter, B.A., B.Sc.—Thursday, 9th February, 8 p.m. Special lecture on "Etching and Mezzotint Engraving," by Professor Hubert Herkomer, A.R.A.—Friday, 10th February, 8 p.m. Indian Section. Paper to be read on "The Work of the Afghan Frontier Commission," by Captain Manisfold, R.A.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, 6th February, 8 p.m. Paper to be read on "The Alkaloids: a Review of the Synthetic Methods of Preparing 'Closed Chain' Azo-carbon Compounds," by Dr. H. E. Armstrong, F.R.S.; and "Studies in Coal Distillation," by Mr. Lewis T. Wright, C.E.

ROYAL INSTITUTION OF GREAT BRITAIN.—Monday, 6th February, 5 p.m. General monthly meeting.—Friday, 10th February, 9 p.m. Lecture on "Safety Lamps in Collieries," by Mr. W. H. Preece.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 7th February, 8 p.m. Ordinary meeting. Paper to be read with a view to discussion, No. 2208, "The Alexandra Dock, Hull," by A. C. Hurtzig, M.Inst.C.E.—Friday, 10th February, 7-30 p.m. Students' meeting. Paper to be read on "Arched Ribs and Voussoir Arches," by H. Medway Martin, Wh.Sc., Stud.Inst.C.E.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Wednesday, 8th February, 7-45 p.m. Discussion on the paper on "The Combustion of Coal, and some Evaporative Experiments with Natural and Forced Draughts," by Mr. W. G. Spence. Paper on "The Results of some Experiments made on Rowe's Double Strapped Butt Joints," by Mr. James Patterson.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—Thursday, 9th February, 8 p.m. Paper to be read on "Alternate Current Transformers, with special reference to the Best Proportion Between Iron and Copper," by Mr. Gisbert Kapp.

PHYSICAL SOCIETY.—Saturday, 11th February, 3 p.m. Annual general meeting. Paper to be read on "The Limit of Refraction in Relation to Temperature and Chemical Composition."

PRICES CURRENT, 2ND FEBRUARY.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER has during the past week been irregular, fluctuating from £73. 15s. to £79 per ton for Chili bars; at the time of writing £76. 12s. 6d. is quoted. It appears to be steadily recovering from the recent depression, and as it is now understood pretty widely that the French syndicate has arranged with the principal producers of raw copper to limit the production and to regulate the price for the next two or three years, it may be expected that prices will steady to the new level, and that buyers will come forward. It is quite clear that the syndicate is powerful enough to accomplish their objects, at least for some time; and as very little copper has gone into consumption for many months, the stocks of manufactured copper at home and abroad must be getting very low. The slackness, however, continues, the copper trade in all its branches being almost at a standstill.

TIN has again advanced, on account of a steady demand for America; the stocks show an increase, but the consumption continues to be large.

LEAD unchanged and steady at slightly lower prices.

SPELTER is flat, but stocks are small, and the market shows signs of recovery.

POLYGONAL WHEELS FOR LOCOMOTIVES.—We quote the following from the *Railroad Gazette*, of New York, respecting a new departure in the design of locomotive driving wheels. Our contemporary says: "A locomotive possessing several unusual features has been recently built by the Hinckley Locomotive Company, of Boston. The engine is designed to run fast passenger trains, and has a single pair of drivers, 67in. diam. on tread, and a pair of 42in. trailing wheels with radial motion. The front end of the engine is carried on a four-wheel truck as usual. The engine has piston valves, but the most novel feature is the form of the tread of the driving wheels. The circumference of the tyre, instead of being a true circle, is polygonal, and formed of 105 flats, each about 2in. long. The object is to prevent slipping. The engine has not yet been tried, but it is claimed that polygonal tyres have been running on a four coupled engine on the Boston and Lowell during the last year, with satisfactory results. A flat wheel is generally regarded as damaging to the rails, while the motion of an engine or car with flat wheels is exceedingly unpleasant.

NEW STEAM TUG FOR DUNDEE.—A meeting of the works committee of the Dundee Harbour Trustees was held recently to consider the offers for the construction of a new twin screw steam tug. The offers were six in number, four of them being from local builders, one from Leith, and the other from a Glasgow firm. After examination it was found that the offer of Messrs. Pearce Brothers, Dundee, amounting to £6,700, was the lowest, and it was accordingly accepted. The new tug is to be constructed of steel, and the following are its dimensions: Length, 120ft.; breadth moulded, 24ft.; depth of hold to the top of floors, 10ft. 8in. The light draught of the vessel is not to exceed 6ft. 6in., and with water ballast 8ft. 6in. She is to be fitted with two triple expansion, direct acting, surface condensing engines, with three cylinders of 12in., 17in., and 30in. diam., and having a stroke of 20in. The boilers are also to be of steel, 13ft. diam., 10ft. 6in. in length, with three furnaces about 40in. diam. each, and having separate combustion chambers. They are to bear a pressure up to 160lb. to the square inch. The steamer is to be built under special survey. She is to be classed 100 A1 at Lloyd's, and is to have a No. 3 passenger certificate from the Board of Trade for twelve months. Her equipment will consist of a steam winch, windlass, and all other necessary fittings. The steamer will also be fitted with a strong iron foremast, and a derrick capable of lifting 5 tons. The contract stipulates that the tug must be completed within six months from the date of acceptance of offer.

HOME INDUSTRIES.

MANCHESTER, 2nd February, 1888.

The Cotton Trade.—There is still some uncertainty as to the extent of the crop of American cotton, although it is more than three months since the first delivery of the new growth. The receipts at American ports have been small, but there is little doubt that stocks in spinners' hands are unusually large. In the meantime the delivery has been much greater than that of last year, and it appears probable that the crop will be very near Messrs. Neill & Co.'s later estimate. Prices remain very steady, and do not show any signs of weakness. This state of things naturally reflects on the yarn market, and in consequence there has not been any increase of business this year. Spinners are, however, in most cases favourably situated, having a profitable margin, and being well sold forward. In addition to this many of them are now running short of cotton, and will have to purchase at the higher current prices. These causes indispose them to accept the prices which are being offered by consumers, and the result is that very little business is being transacted. The cloth market is inactive, although at a little less than current rates a good deal of business could be placed. Manufacturers are indisposed to accept lower prices, especially in the face of the firmness in yarn quotations. In the meantime extensions of manufacturing establishments continue. The contracts for a shed to contain 1200 looms at Bank Top, Burnley, have just been let to Mr. George Keighley, of that town. It is stated that a strong syndicate is being formed in this country for the purpose of working a German patent for a process of dyeing cotton before carding it.

A New Limited Company.—The well known firms of Messrs. Tootal, Broadhurst, Lee, & Co., and the Lee Spinning Company, are now amalgamated into a limited liability company, and will in future trade under the style of Tootal, Broadhurst, Lee, & Co., Limited. The capital is to be nominally £1,000,000, of which £300,000 will be held as preference shares, and the remainder as ordinary shares. A reserve of uncalled capital of £302,260 is retained, and all of the shares will be held by members of the present firm. This is a good example of the private limited concerns which have of late years become very popular.

The Ribble Scheme.—The dredging of the Ribble is being steadily conducted, and when the new dredger recently ordered gets to work, considerable progress will be made. Careful soundings have established the fact that the depth of the river channel has materially increased, not only at the actual point of dredging, but also behind it. In the meantime, in order to satisfy that body of ratepayers who have some doubt as to the ultimate success of the scheme, the Corporation has determined to call in Mr. Deas, C.E., of the Clyde Navigation Trustees, to examine and report.

LONDON, 2nd February, 1888.

The Money Market.—Money continues to be a drug in Lombard-street, one explanation being that a stringency was anticipated about this time, and those who had money to lend arranged that it should be free now. They have rather overdone this, and as the demand is really unimportant, the rates are kept very low by the excess of loanable capital available for use. The Stock Markets continue rather dull. There is still a little speculating going on with copper, and the price of the metal has strengthened again. The Parisian syndicate is gradually embracing all the mines in its toils, and when the few who still hold out are brought into subjection, the higher prices will rule again. The Postmaster-General made rather a rash declaration at Wolverhampton at the end of last week, to a deputation which desired greater telephone facilities. Mr. Raikes said the purchase of the telephone undertakings was only a matter of a short time, which was no doubt reassuring to the deputation. But the Postmaster-General counted without the telephone companies, whose shares bounded up at once, calming down a little when Mr. Raikes attempted to explain away his untimely remark. Among recent issues of an industrial nature is a company formed to work the patents for making glass bottles by machinery, to which reference was made in *Industries* last week.

Popular Lectures.—The lectures to be given this month at the Royal Victoria Hall include "Germs in the Air, and What They Do For Us," by Dr. Percy F. Frankland, B.Sc., F.C.S.; and "Earthquakes and Volcanoes," by Mr. E. Wethered.

Companies.—Since our last report the following new companies have been registered: The Skytmyr Copper Mines, Limited, with a capital of £120,000, to acquire copper mines in the county of Nedenoes, Norway; Booysen Land and Mining Company, Limited, with a capital of £120,000, to explore farms, lands, minerals, &c., in South Africa; Central Argentine (Carpa Valley) Exploration Company, Limited, with a capital of £120,000; the Sussex Mineral Waters Company, Limited, with a capital of £5,000; Joseph Robinson & Company, Limited, with a capital of £100,000, to carry on business as cement and plaster manufacturers at Knothill, Cumberland; Vulcan Fire Brick Company, Limited, with a capital of £10,000; Bradley Water Works Company, Limited, with a capital of £600; North Australian Mining Company, Limited, with a capital of £100,000; J. F. Blyth & Company, Limited, with a capital of £10,000; Worcester City Mills Company, Limited, with a capital of £5,000; Darling & Sons, Limited, with a capital of £50,000, to carry on business as printers, lithographers, &c.; Stannaries Company, Limited, with a capital of £10,000, to work mines, quarries, &c., in the United Kingdom; and the Discoveries, Limited, with a capital of £20,000, to acquire any novelties, new inventions or discoveries.

Produce.—The sugar market has been very quiet, and speculative purchases of beetroot sugar have been made at a decline. Coffee continues to be very depressed, and prices have fallen. A proposal is on foot to establish a clearing house in London for time bargains in coffee and sugar, on the lines of the Caisse de Liquidation at Havre. The clearing house would act as stakeholder between buyer and seller, each of whom would make a small deposit. This would create a feeling of greater security, and Messrs. N. M. Rothschild & Sons, Baring Brothers & Co., and other prominent firms are interesting themselves in the matter.

Hemp.—The demand for Manilla hemp has been fair, and the arrivals this year have been easily disposed of. The Russian market is reported as firmer. No change has taken place in the price for spot parcels of Baltic hemp. There is but little doing in Italian hemp, the prices for which, however, remain firm.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 22nd January, amounted to £1,100,462, on 15,830¾ miles, as compared with £1,083,146 in the corresponding period of 1887, when the mileage was 15,706¾ miles. An increase is thus shown in the mileage of 124 miles or 0·7 per cent., and in the receipts of 2·4 per cent.

The Navy.—The torpedo cruiser "Tartar," which was built by Messrs. Thompson, of Clydebank, has now been completed for sea at Sheerness. Her engines are of 3600 h.p., and she is able to steam at the rate of 17 knots per hour. Two new sloops are to be built of a similar type to the "Daphne," which is being built at Sheerness. The engines will be of 2000 h.p.

Engineering Students for the Navy.—Among the alterations to be carried out in connection with the training of engineering students for the navy, no entries are to be made this year, and the maximum age for 1889 is to be extended to 17 for that year only. Bonds and indentures are to be abolished, and the regular course of training will be reduced to five years, and under certain conditions to four years.

GLASGOW, 2nd February, 1888.

Glasgow International Exhibition, 1888.—The progress of the arrangements was reported at a meeting of the Executive held last week. The buildings are rapidly approaching completion, and about six hundred men are at present employed upon the works. It has been arranged to erect a stone gateway at one of the principal entrances, and to fill it with an iron gate. The electric light installation is now being proceeded with rapidly, and the work of the various sections is in an advanced state. Foreign exhibits have already begun to arrive. The machinery section will be 330ft. long by 285ft. broad. In addition to the floor space there will be a gallery round three sides, which will accommodate light pieces of machinery. Upwards of three hundred applications for space in the machinery section have been accepted, and the committee are at present engaged in allotting the space to the proposed exhibitors. The electric light section, containing dynamos, four steam engines and nine Lancashire boilers, forms an annexe to the machinery section, and is 118ft. long by 100ft. broad. Altogether the floor space of the whole Exhibition will be 474,500 sq. ft. The fountain to be erected by Messrs. Doulton is in course of construction, while the culvert and the excavations have been made for the fairy fountain to be supplied by Messrs. Galloway. The contracts for the steel shafting, and for the steam pipes for the Exhibition, have both been placed with Messrs. Kesson and Campbell, Parkhead.

Patent Boat Apparatus.—There was exhibited at the Royal Exchange this week a model of Evans' apparatus for connecting and disconnecting boats from the davits. The device is intended to secure automatic action of the lowering gear, and simultaneous release of the boat when it has reached the water. The patentee is Captain Evans, of the Shaw-Saville Line.

Shipping.—The demand for freights outwards was fairly energetic last week. Cotton goods to the value of £84,000 went to India and to China, and to the value of £12,000 elsewhere. Iron manufactures to the value of £28,000 went to India, and £22,000 elsewhere. This week the market is a little easier, the number of vessels having come up to the demand. Shipments of coal and pig iron show a considerable increase. The year, so far as it has gone, exhibits a great increase on coal and on pig iron shipped coastwise, but a reduction on pig iron shipped abroad.

Clyde Steam and Sailing Ship Association.—A series of addresses to the members of these Associations, dealing with important subjects specially relating to mercantile law and shipping management, was arranged for early in the winter. The fourth of these was delivered on Monday evening, by Mr. James Mackenzie, on "The Relative Province of the Charter Party and the Bill of Lading." He stated the existing provisions of mercantile law in this connection, and suggested that charter parties should be made more uniform in their terms than is now the case. He also urged that great care should be observed in describing the class and carrying capacity of the vessel, and her position at the date of the charter party. He also urged that the greatest care should be taken that the bill of lading accords with the charter party. The exception of risks, and other important questions which arise in practical business, were referred to at length. Mr. Mackenzie concluded by urging clearness and precision in framing charter parties, and pointed out that mere deletion of a clause in a printed charter party did not imply agreement to its opposite. He also reprobated the practice of permitting informalities, such as the insertion of an untrue date, or the signing for goods as sound which were known to be damaged. These joint meetings of the Associations have been well attended, and have been highly successful.

Shipbuilding.—Messrs. Fleming & Ferguson, Paisley, have booked an order from Mr. Walker, the contractor for the Manchester Ship Canal, for a powerful twin screw dredger. The vessel will be fitted with Messrs. Fleming and Ferguson's patent quadruple expansion engines of 700 h.p., and will be constructed to raise from a depth of 35ft. a quantity equal to 600 tons per hour.

Diminution of Postal Facilities.—An alteration in the arrangements of the Caledonian Railway has been made, by which the train which formerly left Glasgow Central Station for London and intermediate stations at 6 a.m. has been withdrawn for some unexplained reason. This train carried a mail which was made up in Glasgow at 5-30 a.m., and which was delivered in Manchester early in the afternoon, and in London the same evening. The result is that the first mail train for the South is that leaving at ten o'clock, but letters dispatched by it are not delivered until the next morning. It is to be hoped that the railway and postal authorities will see their way to resume the former arrangements, both in the interests of the travelling public and of the postal system.

Carbrook Forge and Bessemer Steel Company.—This well known Sheffield firm have appointed Mr. Robert Horsburgh, 48, Robertson-street, Glasgow, as their representative for Scotland.

Edinburgh Cable Tramways.—On Thursday and Friday last, experimental runs were made over the new cable tramway in Edinburgh, and public traffic was commenced on Saturday. The steepness of the hill on which a considerable portion of the tramway is constructed, offers peculiarly favourable conditions for success.

(From our own Correspondents.)

LIVERPOOL, 1st February, 1888.

The Liverpool Electric Supply Company, Limited.—Since the granting of the license by the Board of Trade for the laying of the wires, &c., underground, and other important provisions, the company has made rapid progress with the extensive new premises in Harrington-street, which, when opened, will be their central station. The buildings are nearly completed, the three boilers are seated and bricked up, and the foundations for the dynamos and engines are well advanced. It is expected that the whole station will be in actual working order early next month.

Compressed Air Engines on the Tramways.—At the general meeting of the shareholders of the Liverpool Tramway and Omnibus Company, held last week, the chairman, Sir David Radcliffe, stated that although every facility and opportunity had been given to Colonel Beaumont to experiment with his engine on the lines at the North End, it was found that the system in its present state of efficiency was not suited to the traffic of the city, and could not therefore be adopted.

The Timber Trade.—The total amount of timber of every class imported last year amounts to 395,003 tons, against 398,094 tons in the previous year; and although the decrease is only about 3000 tons, yet the improvement in the trade which was anticipated this time last year has not been realised. The stocks now in hand are not heavy, and if the foreign shippers will only be moderate in their exports, a fairly remunerative business would follow. Of Honduras mahogany there have only been six cargoes imported, against thirteen the previous year; for six months there was a total cessation of imports, which had a decidedly beneficial effect upon the market. Tabasco has consisted of large sized wood, but much of it faulty, the prices ruling low in consequence; the prices have lately advanced 20 per cent., and the market is bare. Minatitlan and Placotalpam have been chiefly of small wood, the imports being greater than that of previous years. Prices have been low, with an increase on recent sales, as there is only one cargo in stock. African mahogany has been very little imported; the supply and quality cannot be depended upon. The supply of St. Domingo and Cuba has been very insignificant. The imports of cedar from Honduras and Cuba have been very small, and that from Mexico was about one-fifth that of the previous year, and is the smallest on record. From the West Coast, Central America, and Australia none has been imported worth mentioning. There has been a moderate supply of American walnut, which sold at steady prices ex quay. Satin walnut was in brisk demand last year, at varying prices, which have fallen off latterly, and stocks have accumulated.

SHEFFIELD, 1st February, 1888.

Iron and Steel.—There is not much alteration in the condition of local trade, which continues on the whole very brisk. At the rolling mills there is much activity, and the engineering firms are better employed than they have been for some time past. Heavy machinery is in extensive

Digitized by Google

demand just now, and one Sheffield house is engaged on plant to be sent to China. At most of the large works employment is tolerably plentiful, and recently good orders for heavy material have been received. For railway material there is a steady demand with firmer prices, and tyres, axles, and springs are selling readily. In the lighter branches of industry trade is satisfactory. Edge tools find a ready market, and the export of sheep shears to the Colonies is very extensive. In cutlery and electro-plate business is more profitable, and is daily increasing. There is now a probability of the small-pox epidemic being speedily stamped out; and it is satisfactory to state that the Sheffield manufacturers and working men have acted with great energy in checking the disease. The working men have established funds with which to pay the wages of their fellow workmen who have stayed away from work because of the small-pox in their homes; and the manufacturers have in many cases not only persuaded their men to be re-vaccinated, but have defrayed the cost.

NORTH STAFFORDSHIRE, 1st February, 1888.

The Iron Trade.—The improvement noticed at the close of 1887 is not being maintained, more particularly with regard to finished iron, and prices are receding. The present outlook for the year is by no means favourable, and iron masters fear that the expected revival is to be again postponed. Only those actually engaged in the trade know what this means. Owing to its land-locked position, North Staffordshire has to bear a heavy burden of railway or canal charges, and it is a fact that, even without these, recent prices would have been unremunerative. The critical time with regard to prices of the crude metal will be a few weeks before next quarter day, when consumers will be in the market. If makers can hold out for an advance at that time, buyers will contract at higher figures, and the value of finished iron must necessarily be enhanced.

Checkweighmen.—At the Hanley Stipendiary Police Court, on Monday last, the Hanley Colliery Company summoned their checkweighman for "affixing on the colliery a certain notice calling a meeting of the driftmen employed in the said colliery, in consequence of which the workmen absented themselves from their employment," and, under sub-section 4 of section 13 of the New Mines Regulation Act, asked for his removal. In granting an order for his removal, the Stipendiary said it was perfectly clear that the man had been attending to matters far beyond his authority. At the same court, a large number of men were summoned by the same firm for absenting themselves from work; but the summonses were finally withdrawn on payment of costs. The working of the new Act with regard to shot firing is responsible for this and much more trouble in the district.

DERBY, 1st February, 1888.

Local Trades.—The recent improvement in the iron industry is well maintained, and inquiries for plates and bars come in freely. The stove grate makers had an accession of orders with the New Year, which enabled many houses to clear their stocks, and still retain some lines on hand to keep their men busy. In this branch Messrs. Russell & Son are well employed, their combination kitchener, which can easily be changed into an open or close range, being in great demand. Messrs. Pooley & Sons' branch establishment in Derby has been for some time and still remains fairly well employed, owing to the Markets and Fairs (Weighing of Cattle) Act, 1887, which came into operation on the 1st January, 1888. This Act makes it compulsory that at every market or fair where tolls are levied, provision shall be made by the owners or trustees for the official weighing of cattle. At the Derby cattle market this firm have laid down one of their patent weigh bridges, especially adapted for the purposes of the Act. The collieries in the district are working well, and a heavy tonnage of fuel is being sent away to London.

The Colour Industry.—Messrs. Leech & Neal, one of the largest firms in the kingdom in this trade, are very busy on American demand, their "Indian reds" especially being in great request. Other local houses in this line are also busy, and general improvement is manifest in a branch which has been somewhat depressed of late.

Railway Matters.—Great satisfaction is felt that the Beighton and Chesterfield Railway Bill, promoted by the Manchester, Sheffield, and Lincolnshire Railway, has passed the preliminary stage, as the new line will open an important coal field, and is likely to improve the trade of the district. The Midland Railway also have complied with the standing orders in regard to their Bill for amalgamating with their undertaking that of the Dore and Chinley Railway, and extending the time of its construction. Long Eaton, which, from a place of 1500 inhabitants in 1860, has in the interval, chiefly through the lace and similar industries, grown into a town of upwards of 10,000, is agitating for easier access by road to Trent Station, as the present carriage way is a winding one, and very inconvenient. Upwards of one hundred navvies were sent away from Ripley last week, and sent elsewhere to carry on the new line. This has emptied a number of houses in Ripley, and the circumstance necessarily affects the business of local tradesmen.

The Derby Tramways Company.—This company has just declared a dividend of 2s. 6d. per share for the past half year. Gross receipts for period £5,065, expenses £4,357, profit £708. Number of passengers carried 1,163,890, and car mileage run 123,154 miles.

BARROW-IN-FURNESS, 1st February, 1888.

Improvement in Trade.—In both the iron and steel trades there is an improvement to note this week. The quieter tone which characterised the hematite iron trade last week, in consequence of "bearing" operations on the Glasgow Exchange, has given place to a much better tone. There is a good demand for all classes of pig iron alike for prompt and forward deliveries, but prices have not improved, and are this week quoted at 44s. to 44s. 6d. per ton net f.o.b. for Bessemer numbers, and 6d. to 9d. under this price for forge and foundry sorts. The proposal to increase the make of iron has been checked in consequence of the lowering tendency of prices, and will not be resorted to, except under more favourable conditions than at present exist. The steel trade is steady, and there is an improvement to note in the demand for rails; but no change has taken place in prices, which remain steady at £4 per ton for heavy sections, and £4. 5s. per ton for light sections net f.o.b. Blooms are in better request on American account, at from £3. 12s. 6d. to £3. 15s. per ton. In a short time there will be a great increase in the output of steel in this district, as for some time past the works at Moss Bay, as well as those of the West Cumberland Iron and Steel Company, Workington, have been stopped during repairs. A good trade is doing in billets, bars, wire, and hoops, and wire rods and slabs are quiet.

Shipbuilding and Engineering.—There is a better trade doing in engineering in the district, both in the general and the marine departments; and it is almost a certainty that some large orders will be booked to supplement those already on the list. In shipbuilding next to nothing is doing, but preparations are being made on a large scale for what promises to be after all a very brisk year at one of the chief works in the country, viz., that of the Barrow Shipbuilding Company.

Iron Ore and Coal.—There is a great development going on in the iron ore mining industry of the district. The improved demand has not only set to work a largely increased number of men, but explorations have been made to prove the further existence of metal; and at the present time there is as much ore "in sight" as at any previous period of the history of this trade in Furness and Cumberland.

MIDDLESBROUGH, 1st February, 1888.

Pig Iron.—There was rather a scanty attendance on 'Change at the weekly market held yesterday, and the business done was but trifling. Makers being well sold do not care to offer at present prices, and there are no inquiries of importance. Prices thus are merely nominal, at 32s. per ton for No. 3 G.M.B. for February delivery. Warrants are 32s. per ton cash for Connal's No. 3 G.M.B., and 44s. for Connal's Nos. 1, 2, and 3 hematite.

Shipments of Pig Iron.—These have increased over those of the corresponding month in last year by upwards of 15,000 tons, and the improvement is both in home and foreign shipments. Up to the 30th ult. they amount to 57,465 tons, against 42,185 tons to similar date of the same month last year. The usual monthly returns are eagerly looked forward to, and if favourable it is expected that the price will advance accordingly.

Manufactured Iron and Steel.—Finished iron is unchanged, and maintains the improvement it gained. The annual meeting of the Board of Conciliation and Arbitration for the Manufactured Iron Trade, was held on Monday, when congratulations were expressed at the improvement. But the improvement, it would appear, came so late in the year as to have little effect on the year's returns. There has been less turned out in 1887 than in the previous year, the figures being 268,796 tons 17 cwt., as compared with 284,188 tons 19 cwt., and there has been no substantial increase in the price, the figures being £4. 12s. 8·69d., as compared with £4. 12s. 7·83d. In 1884 the output was 428,286 tons, and the average realised price £5. 5s. 6·99d. Finished steel is much the same, with prices unchanged. There is not so much pressure on the works, so that the North-Eastern have been in no hurry to resume after the holidays, when they were stopped for repairs. The lock out, however, has ended to the satisfaction of all concerned. The Board of Conciliation and Arbitration for the iron trade expressed a belief at their recent annual meeting that they could be of great use in steel as well as in iron disputes.

SUNDERLAND, 1st February, 1888.

Shipbuilding.—Additional orders come slowly to hand, but doubtless the thinning of fleets by the winter storms will give further impetus to the revival in this local industry. Messrs. Short Brothers, Pallion, have been fortunate in securing one or two orders since the New Year, and it is believed other shipbuilders have been similarly successful. The large amount of repairing work on hand is noteworthy, all the dry docks and slipways being kept actively employed. An instance of the rapid work effected in fitting engines and boilers into steamers, and completing their deck work, outfit, &c., is seen in the case of the steel steamer "Scottish Prince," which was launched on the 2nd ult., and on the 30th ult. was complete in all respects, and loading cargo.

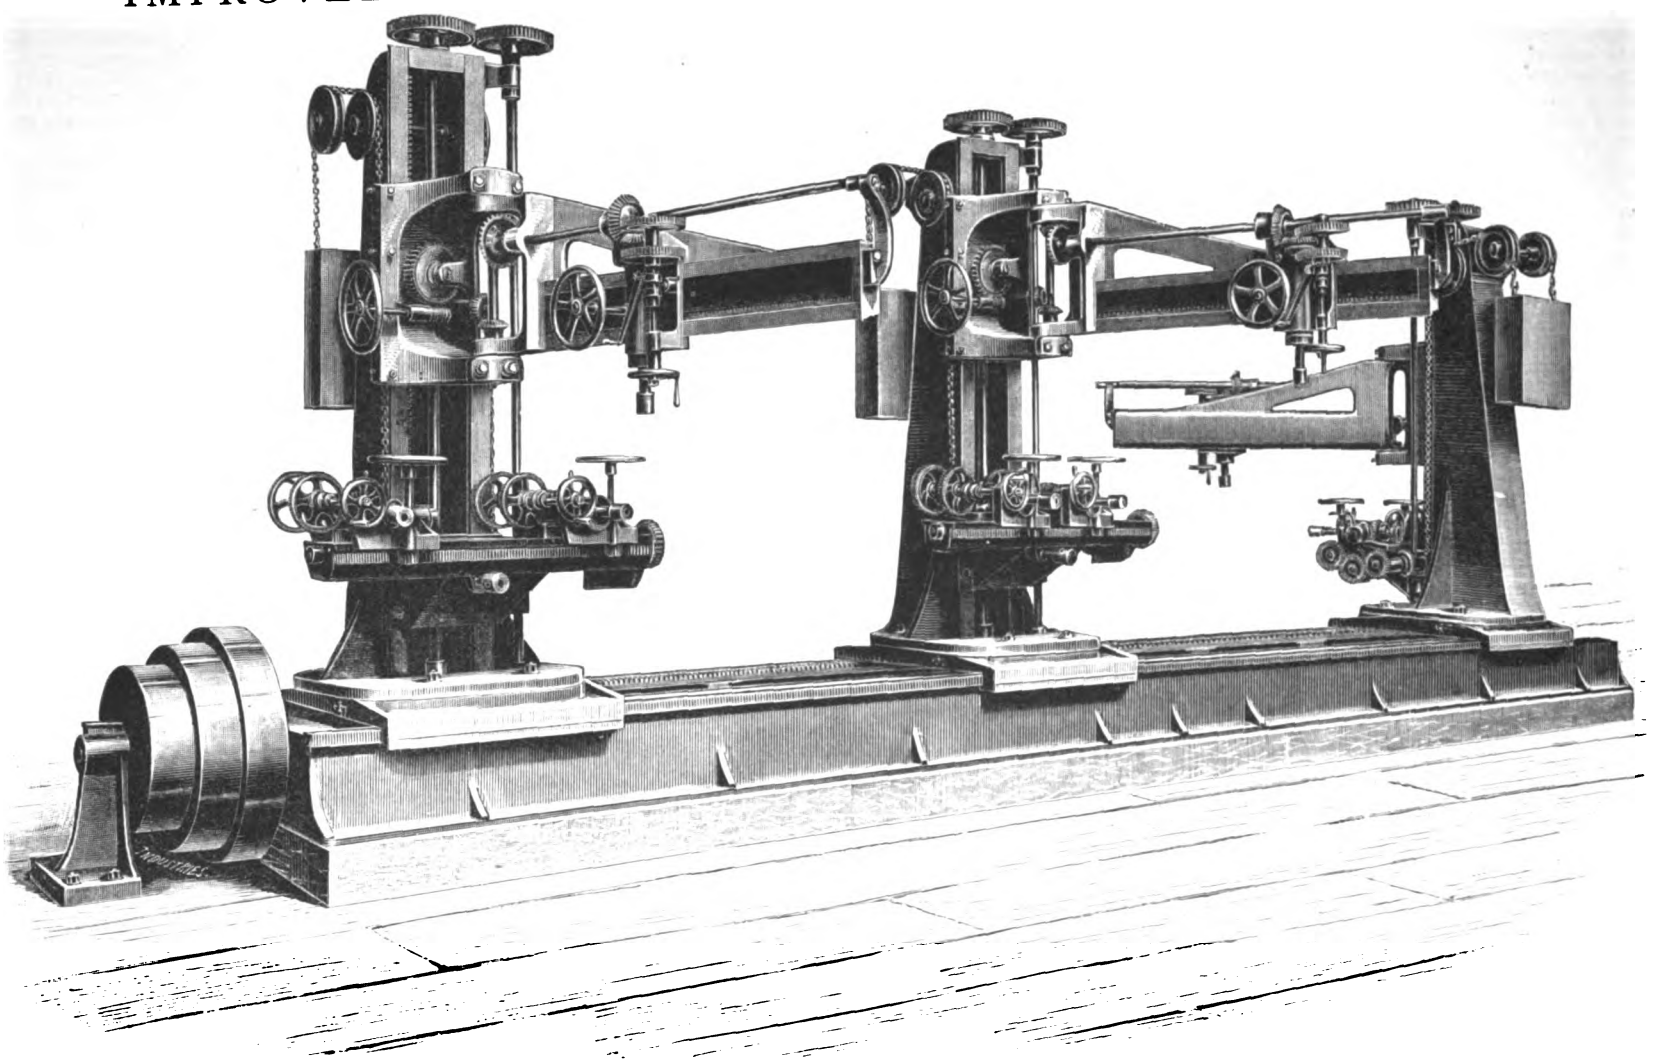
Shipping Trade.—The coal shipments for last week were to foreign ports, 19,058 tons; coastwise, 50,438 tons; total, 69,496 tons. During the previous week, 74,072 tons were exported. The remaining shipments included 1210 tons of patent fuel, 570 tons of coke, 23,000 dozens of bottles, a cargo of lime and cement, and one of fireclay goods. Large consignments of wheat and potatoes were received. The River Wear Commissioners' annual returns have been completed, and show a very important increase in the trade of the port during 1887, as compared with 1886. The total revenue of the Commission last year was £129,373, as compared with £119,504 in 1886, an increase of £9,869. This was largely caused by the increased shipments of coal, which amounted to 4,261,292 tons, an increase of 315,858 tons over the year 1886.

Paper Manufactories.—All the paper mills are actively employed at Hylton, Deptford, and at Hendon. At the latter the new mill, No. 3, is now in active operation, having been completed at the close of last year. By this addition, the number of employés has been increased by about one hundred, and the production of paper by the Hendon Paper Works Company, Limited, is raised from 90 tons to 135 tons per week. The mill cost about £30,000, including machinery.

NEWCASTLE, 1st February, 1888.

Iron.—Though prices in the finished iron trade have undergone little alteration lately, and are still far from remunerative to manufacturers, the demand has greatly improved, and at some of the principal works the production is at least 50 per cent. greater than at the corresponding period of last year. Messrs. Hawks, Crawshay, & Sons' rolling mills are now being worked with a regularity unknown for years past, and their puddling furnaces are also kept in constant operation. The same may be said respecting Messrs. John Abbot and Co.'s mills, in the immediate vicinity; and the pressure of work at Messrs. Raine & Co.'s mills, Winlaton, is quite as great as it has been at any former period. Among other important contracts secured by the last named firm may be mentioned one for a large quantity of smithing iron from the North-Eastern Railway Company, and another of equal extent, for a similar description of the material, from Messrs. Armstrong, Mitchell, & Co. On the whole, though there is little probability of the demand for finished iron becoming so strong as to cause any sudden or extraordinary upward turn in prices, it is generally felt, by those most interested in the fortunes of the industry, that during the present year at all events a fair measure of business will be done.

Steel.—The new steel works which have recently been erected by the Consett Iron and Steel Company, have commenced operations, and are already helping to satisfy the want so greatly felt of late for the different descriptions of steel required in boiler and ship construction. The Company are pressed with orders, the high quality of the material manufactured being generally recognised; and largely as their productive resources have been increased, they will be taxed to the uttermost to supply the demand upon them for many months to come. The new steel furnaces now in course of erection by Messrs. Hawks, Crawshay, & Sons, are expected to be ready for commencement of productive work early in March. The manufacturers of steel and iron sheets are still exceedingly busy, and it is probable that in some instances additional plant, with a view to extended production, will be put down.



Chain and Anchor Trades.—Improving business is the feature to be noticed at different establishments devoted to the manufacture of cable chain; but the anchor making departments connected with such concerns do not show the same tendency towards better trade, owing, no doubt, to the fact that patent cast steel anchors are largely superseding the wrought iron anchors of the old pattern.

DUNDEE, 1st February, 1888.

Flax and Jute Trades.—There has been no improvement in the trade of Dundee and district during the past fortnight. The linen branches have been fairly steady, but the jute trade has been adversely affected by a heavy failure in the bag trade in New York, in which some local firms are involved to a considerable extent. In the flax market the tone is quiet, and business mainly confined to small lots for immediate use. Spinners are anxious to ascertain the quality of the new crop before adding to stock. Flax yarns maintain a steady tone, and spinners are inclined to hold for some advance; but manufacturers are not disposed to concede this, as orders now being executed were contracted for on the basis of late values. In linen goods the demand keeps well up, and looms are kept going. Several large Government contracts have been obtained by leading firms in the district for sailcloth, &c., which will assist the heavy end of the trade, and tend to steady prices for other fabrics. The market for raw jute has become quiet, and prices are scarcely so firm as they were. The export of jute from Dundee to Continental ports is increasing, and last week over 1000 bales were shipped to London, which has hitherto been the chief *entrepôt* for the fibre. The market for jute yarns has been affected to some extent by a strike. After being idle for some days the workmen returned to the mills on the old terms, and in view of the weakening tendency in the market mill owners and manufacturers are considering the propriety of lessening production. A general meeting of the trade is to be held this week to discuss the question. In jute fabrics there is a fair inquiry for Hessians, but buyers hold back unless they can place their orders at the lowest point. Sacking and bagging are in steady demand, and there is rather more doing in tarpaulin. Jute carpeting is also moving off freely, and makers are all busy.

IMPROVED TRIPLE RADIAL DRILLING MACHINE.

TRIPLE RADIAL DRILLING MACHINE.

The above illustration represents a triple radial drilling machine, which has been recently made for the Tees-side Iron and Engine Works Company by Messrs. Scriven and Co., of Marsh Lane, Leeds. The machine is intended to drill large girders in position after they are plated; and the girders whilst being drilled are placed on their side with the top and bottom flanges vertical alongside the main bed. The machine consists of a bed 36ft. long with planed slides, on which are three standards, movable along the bed, and each carrying one radial drilling machine with a vertical spindle, which can drill from 1ft. 6in. to 6ft. 6in. from the centre, and swings through an arc of 180°. This radial drill can be moved up or down the standard to suit different sizes of girders; and is used for drilling all holes in the web. Each standard also carries two horizontal drilling spindles for drilling holes in the flanges of the girder, each spindle being carried by a separate saddle capable of being moved along a slide parallel to the main bed. These drills can move along the whole length of their slide and can pass across the face of the standard, the length of the slide being sufficient to enable a length of 4ft. along the girder to be drilled before moving the standard on the bed. This slide is also vertically adjustable on the standard. All the drills have self acting and hand feed motions. The standards are arranged to turn round so as to drill on either side of the bed—the right hand standard in the engraving being shown reversed,—so that whilst one girder is being drilled another can be prepared for drilling on the other side of the bed.

The driving power is communicated to the various drills from a main horizontal shaft adapted for three speeds, and running the full length within the bed. The main shaft is provided with a continuous key way, and sliding upon it are three bevel wheels with feathers, one wheel for each standard or set of drills. The sliding bevel wheel on the main horizontal shaft gears into a bevel wheel fixed on a vertical shaft passing upwards in the centre of the standard. From this vertical shaft motion is conveyed to the horizontal shaft on the radial arm by intermediate gearing, from whence the vertical drill spindle is driven by a pair of mitre wheels in the usual manner. For driving the two horizontal drills use is made of a second vertical shaft, shown on the right of the main standard, which is driven by spur gearing, shown at the top. Motion from this second vertical shaft is transmitted by a pair of mitre wheels to a horizontal shaft in the centre of the saddle, carrying the two drill spindles and intermediate spur gear. From this horizontal shaft, motion is transmitted by spur gear to the horizontal drill spindles placed at right angles to it, through first a short horizontal shaft on the saddle, which in turn drives the spindles by bevel gearing. The saddle is balanced by a weight hung at the back of the main standard, as shown, and the balancing arrangement enables the cross slides to be worked up and down easily by hand, by means of a rack and pinion. The machine, we understand, has done some good work, and in a large girder and bridge yard it cannot fail to be useful. The drills being all on separate saddles and independent one of another, a blunt or broken drill can be easily removed by simply stopping the one spindle affected, and thereby no delay is caused in the other parts of the work.

THE STANLEY CYCLE SHOW.

The eleventh annual Exhibition of the Stanley Club was opened at the Royal Aquarium last Saturday, and will close to-morrow. In point of the number of exhibits the present show is slightly beyond its predecessors, and there is also a fair sprinkling of novelties in matters of detail. When describing last year's show we dealt to a considerable extent with the principles of the modern bicycle and tricycle, and we shall therefore limit our present account to the mention of some of the more important novelties exhibited. The Singer Company, who were the first to bring out multicycles, that is, machines carrying three, four, or more riders, have modified the original design of this multicycle so as to make it suitable for military service, and show a portion of a machine made to the order of the War Office. The whole machine, which is called the Victoria war cycle, consists of six pairs of wheels, and is intended to carry twelve riders. Each pair of wheels, with its frame and backbone, forms an independent section, and can be very quickly detached from and attached to the rest. Experience has shown that six sections are the maximum which can be used with safety and at considerable speeds. The cycle is so arranged that it can be rapidly split up into two independent portions carrying six riders each, or three portions carrying four riders each. The joints at the backbone are all ball and socket couplings, so as to make the machine flexible both in the horizontal and vertical direction. A somewhat similar exhibit, though for peaceful purposes, is shown by the Coventry Machinist Company. This is a hansom cab made to the order of the Sultan of Morocco, which is propelled by four drivers riding behind. The machine has four large driving wheels and a small wheel in front of the cab, which, however, does not touch the ground in ordinary running. Within the cab there are the steering and brake handles. The same firm also show a light tandem racing tricycle, and a 28in. racing tricycle, the latter weighing only 28lb. Messrs. Hillman, Herbert, & Cooper, of Coventry, have a good collection of safety bicycles and tandems. In one of the later exhibits the steering gear is brought forward of the steering axle by about 8in., the two axes being coupled together by connecting rods. The object of this arrangement is to increase the wheel base, without forcing the rider to lean too much forward. A small detail in connection with their treadle also deserves mention. It often happens that the foot of the rider slips off the treadle through the rubbers becoming worn or turning on the studs. To prevent this, a wire is inserted into the corrugations of the rubber, and riveted up in the end plates. Messrs. Starley & Sutton, of Coventry, have a good display of their special Rover bicycles. We notice that they are now introducing a band brake on the hind wheel, instead of the usual plunger or spoon brake on the fore wheel. In this, however, they are not alone, several other firms in the show having adopted these band brakes. The ball bearing on the steering stalk has been made larger this year, in order to obtain one or more complete revolutions of each ball in the bearing with the usual amount of steering. When this bearing is made of very small diameter the balls only revolve through a small arc, and are therefore liable to wear unevenly. By making the bearing of large diameter, this defect is overcome. The Humber Company have their usual large display, amongst which we noticed an exceedingly simple safety bicycle, and a tandem tricycle with a double band brake. To insure ease in running, the steering stalk is supported on double springs. We also noticed an alteration in the Cripper tandems shown last year, the present machine being specially adapted for lady riders.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Offices for Publication:

FRIDAY, 3RD FEBRUARY, 1888.

ELECTRICITY AT THE PARIS UNIVERSAL EXHIBITION.

ENGLISH manufacturers of dynamos, motors, lamps, and electrical appliances generally will soon have to decide whether they will take part in the forthcoming Universal Exhibition at Paris, or whether, following the example of our Government, they will severely keep aloof from an enterprise which, rightly or wrongly, is by many considered to commemorate the centenary of the great French Revolution. It is always to be regretted when political considerations are allowed to interfere with business matters, and in this particular case the interference is the less justifiable as the French authorities themselves do not attribute any political significance whatever to the forthcoming Exhibition, but maintain that the date of 1889 has been fixed as the natural sequence according to which the French Capital has of late seen a great international exhibition every eleven years. We cannot disguise from ourselves the fact that the electric light and power industry has made enormous strides on the Continent, and that English firms, although two years ago they led the van of progress in electrical engineering, are now forced to strain every nerve not only to maintain what Continental business they happen to have, but also to prevent foreigners from invading our own markets. That the latter will surely attempt to do this, is already shown in two instances. A leading German dynamo maker is doing what he can to introduce his machines into England, and a Swiss firm have also lately appointed an agent here for the purpose of importing their dynamos and motors. That others will soon follow we cannot doubt, and our manufacturers would do wisely to ponder well over this state of the electrical engineering trades before they come to a decision with respect to the great international show which is to take place next year. There is no reason why English electrical manufacturers should not predominate in the markets of the world, to the same degree as our textiles, machinery, hardware, and other goods, for which English manufactures have long been famous. As a matter of fact, some of our electrical firms are doing at the present moment a fair amount of Continental and Colonial trade, but not nearly so much proportionately as the makers of agricultural, textile, and mining machinery. Now, this trade requires developing, and the question is whether attending the Exhibition at Paris or abstaining from it will be best calculated to produce this development. It is sometimes argued against exhibiting that the large manufacturer—who has, at a considerable sacrifice of labour and money, produced a machine which is better than anything made by his competitors—by exhibiting enables his rivals to copy his design, and thus to injure him. This may be true in certain exceptional cases; but, as a general rule, a manufacturer has so many opportunities of ascertaining the exact nature and construction of a rival's specialties, that the additional facility given by an exhibition counts for very little. If one man intends to steal the invention of another, he will generally find a way of doing so as soon as the new machine is placed on the market, and sometimes even sooner; but in electrical machinery we are inclined to doubt whether English makers are in possession of inventions of special types of apparatus which would give them a marked superiority over those Continental rivals, whom they are inclined to view with distrust. There is at the present moment no mystery whatever about the design of electric machinery. The general principles of such machinery are known to all the world, and superiority of the productions of one firm over those of another consists mainly in a better design of details, in better material, and in better workmanship. Dynamo makers on the Continent know quite as much as our own manufacturers about good electrical engineering; and they are not likely, for the sake of copying some minor details from the machines of their rivals, to abandon their own type, with which they have had considerable experience. If, therefore, on the one hand, English makers incur no great risk when exhibiting, they will, on the other hand, derive whatever benefit is attached to an international fair of such gigantic dimensions as that of next year is sure to be. To abstain from exhibiting would be a confession of weakness more damaging to the foreign trade of English electricians than the possible but remote disadvantage of teaching the foreigner our ways of electrical engineering. The question concerning the Exhibition is, therefore, not whether it will do us good or harm to exhibit, but whether the good done by exhibiting is in proportion to the expense incurred. In order that those of our readers who are interested in this subject may form their own conclusions, we give herewith a rough outline of the programme drawn up by M. Berger, the commissioner to the electrical section of the Exhibition.

Electrical appliances may be entered either as ordinary exhibits or as part of the plant which is to be used for lighting the Exhibition and grounds. Exhibitors are not charged for space, but will be called upon to pay towards the general expenses of supervision, installation, police, &c., a sum proportional to the space they occupy. They will also have to provide their own flooring and stands. Each national section will have its own attendants, and be subject to the rules and regulations of its own commissioners. Apparatus used for lighting purposes will be looked upon as exhibits, and if desired by the exhibitor, will be so considered by the jury. Power in the shape of steam, water, gas, or shafting will be supplied to the exhibitors free of charge; but no provision has yet been made for the supply of current for charging accumulators or running motors. The total power required for lighting purposes is estimated at 3000 h.p., for which purpose various types of steam boilers and engines will be installed by the syndicate intrusted with the carrying out of the lighting; but these boilers and engines in themselves will probably form exhibits, the syndicate being confident of obtaining support in this manner from the manufacturers of steam power plant. Out of the total power M. Berger offers to the English section, for the use of intending contractors for electric lighting, 500 h.p., at a charge of £40 per 10 h.p.—which is the minimum supplied—for the whole time the Exhibition is open. The admission to the Exhibition during the day time will be 1fr., and during the evening, when the electric light is on, 2fr., the additional franc being equally divided between the general administration of the Exhibition and the electric lighting syndicate. The working expenses of the syndicate will be paid out of the £4 per horse power received from the lighting contractors and out of the half franc extra admission money; and if any profit be left, it will be divided at the close of the Exhibition among the different firms who have taken

Digitized by Google

part in the lighting, in accordance with the amount of power for which they have subscribed. Contractors will have to bear the cost of installing their own machines and arc lamps, provide their own lamp trimmers and attendants, and pay for carbons. Bearing in mind that at the last Electrical Exhibition in Paris, in 1881, a considerable profit resulted from electric lighting, it is more than probable that financially the programme we have just roughly indicated will also be a success, and that the profits made would to a large extent pay for, and perhaps exceed, the outlay of those firms who take part in the lighting.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

At the last meeting of this Society an interesting discussion was held on the paper by Mr. C. Cockburn on "Safety Fuses." These adjuncts have now become so indispensable to electric light installations, that almost every electrician has to take an interest in them; but the consensus of the opinions of the speakers seemed to be that the employment of safety fuses was in many cases overdone. Mr. Killingworth Hedges, who was one of the first to introduce properly designed safety fuses, pointed out that the arrangements adopted by Mr. Cockburn did not differ in principle from those which had long before been invented by Sir William Thomson, as could be seen by inspecting a collection of these early fuses which was exhibited. He strongly advocated that all fuses should be made to a common standard, and stamped with the current at which they are intended to melt. Professor Sylvanus Thompson pointed out that the size and material of the terminals must influence the fusing point of any given wire, an observation which was confirmed by Mr. Cockburn in his reply. The influence of a variation in the size of terminals is, however, eliminated by making each fuse wire so that it can only be clamped between terminals of a certain size. Mr. Preece made some very interesting remarks on the theoretical side of the question. He pointed out that the indefinite multiplication of safety fuses is in itself objectionable, because every fuse introduces the possibility of a bad contact, and to show to what absurdity the mania for an abundant use of safety fuses may lead, he instanced the case of a single building, in which he found no fewer than 6000 bad joints, owing to safety fuses being scattered all over the installation. In his opinion, nine out of ten failures of the electric light are directly attributable to bad contacts at the safety fuses. The principle of protecting cables by such fuses is not new. In fact, for the last twenty years telegraph cables have been protected by fuses, in addition to the vacuum tube and the flat plate lightning protector. These fuses consist of fine platinum wires, which are intended to melt before a discharge of atmospheric electricity can reach the core of the cable. It is necessary to bear in mind that the fuses used on cables must be exceedingly sensitive; the strongest working current in many cases is only slightly smaller than the weakest discharge of atmospheric electricity, against which the cable is to be protected, and hence there is only a small margin within which the fuse must act. Long experience has taught telegraph engineers that platinum is the only reliable material for such a purpose, and recently Mr. Preece made a long series of experiments to determine the exact fusing currents for different sizes of platinum wire, and of wires drawn from almost any other metal which could be used for the purpose. He found that for wires above 10 mils. the fusing current is given by the formula $C = a\,d^{\frac{3}{2}}$, where a is a constant depending upon the nature of the metal, and d is the diameter of the wire in mils. The formula only applies to such lengths of wire for which the cooling effect of the connections may be neglected—that is, for thin wires about 6in. long. He has, however, also repeated the experiment with wires 1¼in. long. The experiments were made to ascertain three conditions of the fuse wire. The first with a current which produces a temperature of 98°F. to 100°F., which will just give the sensation of warmth to the touch; but he found that the personal error in estimating the sensations of warmth so great as to vitiate the value of these experiments, and he therefore substituted for this test that of melting a thin flake of shellac, which was placed on the wire. The shellac melts at 77°C., and the experiments of the first stage were all taken for this temperature. The second stage of experiments was with reference to the temperature at which the wire becomes just visible in the dark. From the fact that all substances become just visible, that is to say, dull red at the same temperature, which is 525°C., the corresponding current for this temperature could also be ascertained with great accuracy. The third series of tests referred to the fusing current of wires made of copper, aluminium, platinum, German silver, platinoid, zinc, tin, lead, and an alloy of tin and lead. The thickness of the wires varied between 10 mils. and 40 mils. Mr. Preece found that platinum has some very valuable properties when used as the metal for a fusing wire. From his experiments, he found that if the current which a platinum wire will carry to melt a flake of shellac be called unity, the current which will make it dull red is twice as much, and the current which will fuse it is three times as much. We have thus the simple proportion of one, two, three for these three characteristic currents; and if the cut-out be exposed to view, it is possible to see by its appearance when the fusing point is being approached. As compared with tin, lead, and all other metals, platinum has also the advantage that it does not scatter molten particles about when fusing. As a general rule a cut-out does not melt owing to a slow and steady increase of current, but it melts suddenly upon the establishment of a short circuit or very heavy leak. In such a case a perfect shower of molten metal is scattered about if the wire consists of tin or lead, but with platinum wire the break occurs quietly without any scattering of molten particles. Mr. Preece strongly condemned the double pole fuse, because of the danger of a short circuit being established on the dynamo side of the fuse. Such a case actually came under his notice only recently, when an American visitor, in one of the London hotels, amused himself by bridging the two poles of a double pole fuse with his keys on the dynamo side of the fuses, so that, of course, the latter were quite unable to protect the branch leads. Mr. Preece does not condemn fuses on both branches, but he strongly objects to their being placed side by side.

Professor Ayrton corroborated Mr. Preece in his statement of the law for the current strength at which wires melt, but drew attention to the fact that this law only holds good for wires above 10 mils., for smaller wires the formula to be used is $C = a\,d$.

Sir David Salomons, who has had a long experience of the electric light in his own house, contrasted the imperfect methods of wiring and protecting lamps in the early days of electric lighting with those in use at the present time. In 1874, according to his experience, fuses went daily; but by degrees the wiring became more perfect and short circuits the exception, whilst also the fuses themselves became more reliable. He believes, however, that the length of time a fuse is in use will influence its melting point, and from his experience the older the fuse is the more current will it carry. He does not think there are any fuses in the market which can be absolutely relied upon. If we wish to work with certainty we must use an electromagnetic cut-out, such, for instance, as that invented by Mr. Cunynghame. He also deprecated the tendency to multiply switches and fuses to an unlimited extent, and thinks that the combination of fuses with switches is an advantage because of reducing the number of contacts. As to the claim of fuse makers to be able to protect single lamps, he considers it almost impossible, and, at any rate, very undesirable. It is better that occasionally a lamp should go, than that the lights should be extinguished at all times by the premature melting of the single lamp fuses, which must necessarily be adjusted with an insufficient margin.

Mr. Crompton spoke rather deprecatingly of the improvements introduced by Mr. Cockburn in his fuses, and also of the many other special modern designs of fuses now in the market, saying that his own very simple tin wire fuses, which were put up many years ago, have proved quite good enough for all practical purposes, and are in use to the present day. The difficulty is not one of construction but one of position, and on the latter point Mr. Cockburn's paper gave no information. A fuse should be put so as to be easily accessible, and it would require branch fuses to be fixed at some distance from the main; but to protect the whole of the branch, the fuse would have to be placed at its root where it leaves the main. Thus in most cases the two conditions are contradictory, and to reconcile them he has in several installations adopted the plan originally introduced by Mr. Henry Lea, of Birmingham, according to which all the fuses are placed in one box close to the main, from where all branches are taken through the house. Mr. Crompton spoke strongly against the hobby of having every switch, fuse, and other fitting mounted on slate, asbestos, porcelain, or other incombustible material. He thought it perfectly ridiculous that hard wood should be excluded from use in fuse boxes, when tin was the material employed for the fusing wire. It was utterly impossible to set fire to hard, well seasoned wood by molten tin; but the use of wood enabled them to get a high insulation resistance, which with slate was not the case. The double pole cut-out he characterised as a "Yankee absurdity," and a decided element of danger; and if he wanted to protect both leads, he would use two single fuses in preference. He thought that the Phœnix Fire Office rules went too far in imposing a multiplication of switches and fuses, especially when the fittings are put on slate. Slate is a bad insulator, and although the cables may be of the highest quality, it is impossible to get a high insulation throughout the building if slate forms any part of its fittings. Mr. Mordey said that the only way slate could be made an efficient insulator was to immerse the slate a little way in melted paraffin, without, however, covering the top. After a time the top surface assumes a greasy appearance from the percolation of the paraffin, and, after that point has been reached, the slate is an almost perfect insulator. Mr. Bernstein mentioned a slate quarry in Galicia, where slate oil is also found, and where nature has already paraffined the slate by impregnating it with this oil, thus making it a perfect insulator.

An interesting magnetic cut-out was described by Professor Crookes, who some years ago made use of the properties of nickel to lose its magnetism with a rising temperature for interrupting the circuit. A nickel wire, forming part of the circuit, was pressed against the contacts by the attraction of a magnet, and its size was such that a normal current did not sensibly raise its temperature. If, however, the current increased to a dangerous degree, it heated the metal wire, the magnet failed to protect it, and thus the wire fell from its contacts and interrupted the circuit.

THE LINEFF ELECTRIC TRAMWAY.

A further step in the application of electricity for working urban and suburban tram lines has been made by Mr. Lineff, who is now experimenting at the Chiswick depôt of the West Metropolitan Tramway Company with a small open passenger car running on a short line in the yard. To correctly assign the Lineff system its place among its rivals, it is necessary to briefly review what other inventors have done before. Amongst the first methods for conveying the current from the dynamo at the station to the motor on the car was the overhead conductor, either in the form of a copper tube with a longitudinal slot carrying a contact shuttle, or a solid rod or cable upon which runs a carrier. This arrangement does fairly well for a single line without any crossings or switches, and where the presence of an overhead conductor is not objectionable; but in the majority of tram lines overhead conductors are out of the question, while switches and crossings are unavoidable; and then the complications introduced are so great as to render the system objectionable. In order to overcome this latter difficulty, Dr. John Hopkinson introduced a most ingenious method of collecting the current. In his design the overhead conductor is duplicated, and consists of short spans of cables or wires suspended from cross beams over the track, whilst the collector consists of bars fixed transversely over the roof of the car. The points of suspension of each conductor are on different levels, so that the catenary formed is unsymmetrical, that is to say, the lowest point in the catenary of the left conductor is forward, and that of the right conductor is behind the geometrical centre between the supports. By this means at least one of the conductors must always be in contact with the collecting bar, and no difficulty whatever exists on sharp curves, crossings, or switches. But there is still the general objection to the use of an overhead conductor, and Dr. Hopkinson's system will therefore only be applicable on lines running across country, and not on town lines. To meet such cases Mr. Holroyd Smith introduced his well known underground conductor, which in principle is simply the overhead conductor transferred into a central underground channel. The same objections against crossings and switches apply therefore also in this case, with the additional drawback that the conductor must be a stiff rail, causing trouble from expansion and contraction, and the insulation resistance is necessarily much lower than with an overhead line. With regard to the difficulty of crossings and that of expansion and contraction, Mr. Lineff has done for the underground system what Dr. Hopkinson did for the overhead system; but whether he has succeeded in overcoming the great difficulty of imperfect insulation is a question which only experience can decide. With the Lineff system there is no difficulty whatever in arranging for crossings or switches, and his conductor being subdivided into comparatively short sections, the trouble of expansion and contraction through changes of temperature has also been avoided. The conductor on the line we inspected consists of a ¾in. gas pipe, with a stout naked copper wire drawn through it. At intervals of 3ft. contact pieces are attached to the pipe. These consist of saddle-shaped castings with a central stem, which is screwed through the pipe, and presses down on the copper wire. The pipe is supported by cast iron brackets at intervals of 6ft., which brackets are bolted against the U shaped castings supporting the two rails which form the central slot. These castings are placed 3ft. apart in the concrete trough which forms the underground channel. To protect the rubbing contacts from dirt and moisture, they are set to one side of the surface slot, and the gas pipe is insulated by being wrapped with insulation material where it rests in the brackets. The whole is, moreover, covered with some insulating compound, to

Digitized by Google

reduce surface leakage. Electrical connection between the different lengths of gas piping is made by short pieces of flexible insulated cable. The current is taken off the conductor by means of a stranded steel cable, hanging from shoes at the end of the car, which project through the slot in the usual way. On this cable are threaded gun metal ferrules, ¾in. diam. and 3in. long. The object of covering the cable with these ferrules is two-fold. In the first place, they can be renewed when worn, without having to discard the whole of the collector; and in the second place the danger of having loose and frayed strands, as the result of wearing away the surface of the cable itself, is thus avoided. From the cable the current is led to an Immisch 4 h.p. motor, which works, by means of a Renold's chain, a counter shaft, and from this, by another chain, the axle of the car. The reduction of speed is twelve to one, and the car is designed to run at 6 or 6½ miles per hour. The return circuit is formed by the rails of the line. For places where a central channel is objectionable, Mr. Lineff arranges the conductor under one of the rails; but this system is not so good as that of a central channel, because more water must find its way into the circuit, owing to the curvature of the surface, and also because more dirt is likely to be brushed through the slot by the action of the wheels of the car itself, and of those of other vehicles running over the rails. The resistance of the line is estimated by Mr. Lineff at ·2 ohm per mile, and we are told that the insulation resistance of the short line at the Chiswick depôt is about 200,000 ohms. One advantage of the Lineff system is that it lends itself in an easy manner to automatic block working. For this purpose Mr. Lineff arranges a contact saddle between two of the regular contact saddles belonging to the conductor, but insulated from it and from earth, and when the car is passing the suspended cable establishes for a moment electrical connection between this signal contact and the rest of the conductor, by which means a current may be sent back to block the line, or to switch off the current from a section of the line, or do any other work which may be required in an automatic block system. This is in effect an adaptation of the principle introduced by Professors Ayrton and Perry on their telpherage line. Automatic block signalling would, of course, not be resorted to for town tramway lines; but it would certainly form a valuable adjunct to longer lines running across country. An improvement has also been added to the car, whereby its motion upon meeting an obstacle is automatically stopped and then reversed. The dash board in front of the car is suspended from hinges, and connected by rods with a specially constructed switch, and with the reversing gear of the motor. The switch serves to send a current through a long pull electro-magnet actuating the brakes, and also to first interrupt and then re-establish connection with the motor circuit. This switch is not turned directly by the movement of the dash board, but is under the control of a spring and an air cataract, which is released by the movement of the dash board. The action is as follows: Upon meeting an obstacle a trigger is moved, and releases the spring. The switch is slowly revolved by the force of this spring acting against the air piston of the cataract. By the movement of the switch lever the current to the motor is at once switched off, and at the next moment the current is sent through the brake magnet, the contact for which spans half the circumference of the switch, thus giving the car time to stop. By the time the car is stopped, the switch lever has passed on to another set of contacts which re-establish connection through the motor, the brushes of which have meanwhile been reversed, first by means of resistance coils, and then direct. The car now goes backwards. A similar arrangement is fitted to the other end of the car, so that the latter can be kept going automatically backwards and forwards between two obstacles placed on the line. The automatic reversal of motion we hold to be a useless refinement; but the arrangement of automatically switching off the current and putting on the brake upon the car meeting an obstacle will certainly prove of value in crowded streets. The action of the magnetic brake is extremely rapid, and on the occasion of our visit on Saturday last the car when going at full speed was stopped within a distance of 10ft. On that day a large party of visitors, mostly vestrymen of the neighbourhood, attended to witness a demonstration with this tramway; but, unfortunately, a "short" occurred in one of the circuits, and interrupted the experiments for a time. The fault was ultimately discovered and remedied without difficulty, when the trips were again resumed. Leaving out of consideration this slight mishap, which has really nothing to do with the Lineff system, and which might have occurred on any other electric tram car whilst yet in the experimental stage, the arrangement of underground conduction adopted by Mr. Lineff appears to have several distinct advantages, and it is to be hoped that the West Metropolitan Tramway Company may arrange for a more extended trial of it on a section of their lines.

TEMPORARY IMPORTATIONS.

The French iron trade has been thrown into a state of commotion by a fierce battle fought between the manufacturers of the North and North-east on one side, and those of the Centre and South on the other, over the traffic in *'acquits-à-caution*, or permits to import, which conflict has ended in a victory for the former, and a consequent suppression of that traffic. The hasty uprooting of a practice of this sort which, in some thirty years, has grown to great importance, must seriously disturb the relations existing between the several centres of the iron industry of France, and considerably modify the conditions under which the trade in iron is now carried on. Besides a general interest in the matter, we find ourselves directly involved in the direction of our export trade in pig. The imports of duty paying crude iron into France, that is, iron for consumption in the country, are small—only about 25,000 tons in 1887; but the free imports, that is, iron admitted according to a law of 1836, duty free, under a bond that it shall be re-exported after conversion, are considerable, amounting in 1887 to nearly 100,000 tons. This iron is derived chiefly from Germany and Great Britain. For a time the iron was conveyed, in the custody of the Customs officers, to the works authorised to receive it, whence it was re-exported in another form. This principle of identity was at first rigidly insisted upon; but the cost of transport to the frontier rendered it practically impossible for the manufacturers in the Centre and South to avail themselves of the privilege. The system was, therefore, modified to the extent of allowing an equivalent quantity of French made iron to be exported, instead of that actually received from abroad, in discharge of the bond. Hence arose the traffic in *acquits-à-caution*, which was carried on in the following manner: A manufacturer in the Centre or South having obtained a contract for the execution of work abroad, say a bridge, applies for an acquit, or permit, to import duty free as much pig iron as he deems necessary for the job. This he obtains by signing a bond to pay the duty of 15 francs a ton if he fails to export it, or its equivalent, within a specified time. But, as he cannot profitably use the permit himself by reason of the distance of his works from the frontier, he sells it at a reduced price to some manufacturer in the North or the North-east, who then imports the iron and uses it, the original holder of the permit being held responsible for the duty. The latter then uses French iron, by exporting which within the time specified he discharges his bond. His gain on the transaction is, say 7·50 francs a ton, and that of the Northern purchaser of his permit also 7·50 francs, assuming the reduction allowed the purchaser to be one half the amount of the duty. This practice, though favourable to the users of pig iron in all places, is manifestly unfair to the blast furnace owners of the North and North-east, since it deprives them of much of the protection afforded by the import duty. The system of the equivalent is now to be abolished, as far as forge pig is concerned, six months' notice having been given of the change to be made. It is said that the immediate effect on the industry of the Centre and the South will be to throw 10,000 hands out of employment, and that a more remote consequence will be the removal of the works to the neighbourhood of the frontier.

Letters to the Editor.

THE BOILER REGISTRY BILL AND BOARD OF TRADE INSPECTION.

To the Editor of "Industries."

Sir,—Lord Stanley, of Preston, in moving the second reading of the Boiler Registry and Inspection Bill in the House of Lords, on the 15th August last year, remarked that "he only proposed to ask the House to affirm the principle of the Bill, and did not intend to go further with the measure that session. He hoped to move for a select committee of their lordship's House in 1888 to inquire into the subject. The question would have the advantage of being before the public in the meantime, and of being subjected to the searching criticism which he hoped it would receive. The Government might thus, perhaps, get the means of ascertaining what was the general feeling on the subject, and how far they could deal with this matter at all." Since that time little has been done in the direction suggested, and there appears to be every likelihood that this Boiler Registry Bill will be as quietly passed through both Houses as was the Boiler Explosion Act of 1882, and the whole of the steam power of this country will then pass under the control of the engineers to the Board of Trade. Some idea of what that will mean may be fairly gauged by considering the report No. 242 of the preliminary inquiry into the explosion of a Green's economiser, regarding which your correspondent "Economiser" made some interesting comments in your issue of last week.

Mr. Thomas W. Traill, the engineer surveyor-in-chief, and Mr. William H. Woodthorpe in that report express no uncertain opinions regarding Green's economiser, or with regard to any economiser of a similar class and construction made of cast iron. Mr. Woodthorpe says: "The opinion has frequently been expressed by many that cast iron is unsuitable for use in such structures as boilers, in which class this fuel economiser should properly be included. The cost of the material, and the facility with which it is cast into various forms, renders its use much cheaper than that of any other metal; but it possesses well known properties which make it undesirable that it should be employed in such a manner as in the present case. In addition, the irregularity in the thickness of the tubes cast in the ordinary manner is another serious objection to its use in the construction of economisers. I have reason to believe that these views as to cast iron are becoming more general among engineers, and it is probable that some more suitable material will be employed for such purposes. Apart from the unsuitability of the material, the arrangement of these vertical pipes is most unsatisfactory, as it is quite impossible to examine them externally; the tubes should be differently placed, so as to afford facilities for this purpose, and in existing apparatus provision may be made by removing some of the tubes. . . . . The working of these so-called economisers should be attended to with great care, as only by so doing will disastrous explosions be avoided; and it would be well if the nature of the material from which these apparatus are constructed were fully understood by those interested." Again, Mr. Traill says: "Cast iron, it is hoped, is getting to be regarded as an unsuitable material of which to make such apparatus. I have before expressed my opinion on this point, and I regard such structures, as described in this report, to be a constant source of danger."

Now, what in the opinion of any unbiassed mind would be the probable action of these officials with regard to the continued use of Green's and other economisers now working, if, by the passing of the proposed Registry and Inspection of Boilers Bill, they were put in power, and the steam users of this country subjected to their authoritative interference? Is not the answer self evident? They have already prejudged this particular question. "The working of these so-called economisers should be attended to with great care, as only by so doing will disastrous explosions be avoided," says Mr. Woodthorpe. "I have before expressed my opinion on this point, and I regard such structures as described in this report to be a constant source of danger," says Mr. Traill. Could they consistently allow the continued use of such structures, that would be a constant source of danger, and the disastrous explosion of which could only be avoided by great care? Certainly not. What have steam users, then, to expect? Why, this: that the Board of Trade would, in carrying out their notions of what was due to the public interest, issue such orders and instructions as would compel steam users to discontinue using such dangerous appliances. Green's economisers, to the extent of, I believe, upwards of 1,000,000 h.p., are fitted to steam boilers in various parts of the kingdom, and I may estimate their value at about £4,000,000. Some notion of the vast injury and loss to the steam using public which would be caused by the inspection of the steam power of this kingdom passing under the control of the Board of Trade, can be formed from this instance. It is, perhaps, unnecessary to inform the readers of such a practical journal as yours that there are many other economisers of similar type and material at work, all of which would be similarly affected.

I will not at this stage enter into any question as to the accuracy of Messrs. Woodthorpe and Traill's opinions or the value of their evidence and judgment on this important question, as I simply want to draw the attention of those interested to what threatens them in the immediate future. To carry out these views of the Board of Trade officials would involve the expenditure of about £6,000,000. It would absorb fully that sum to replace the whole of the fuel economisers now working in this country with others made of a material that would satisfy the conditions laid down by the Board of Trade inspectors. It should be noted that the loss which would thus be sustained by steam users would far exceed the whole cost and expenses incurred by every explosion of steam boiler, fuel economiser, or steam generating vessel of any description, which has ever occurred in these realms, since the first introduction of the use of steam power.

Parliament will soon be sitting, and the promoters of the Boiler Registry and Boiler Inspection Bill will be ready to press forward their pet project. I therefore think it behoves the steam using public to be on their guard, and to look to their position in the matter by instructing their various representatives to oppose Board of Trade interference with their working of boilers, otherwise the material progress of this country will receive such a blow that many years will elapse before the injury can be repaired. If ever Board of Trade officialism, as represented by its Marine Department, is allowed to mount the shoulders of our giant manufacturing interest, it will cling to its neck, and continue to ride until it falls half strangled and exhausted, like the unfortunate victims of the other "Old Man of the Sea."

Yours, &c.,
Manchester, 31st January, 1888. Boiler.

CHALK FOR VIOLINISTS' HANDS.

To the Editor of "Industries."

Sir,—Will any of your chemical readers be good enough to inform me what proportion of salicylic acid and chalk are required to absorb the perspiration of violinists' hands, and also what chalk is best?

Yours, &c.,
Manchester, 27th January, 1888. Paganini.

THE TRANSMISSION OF ENERGY BETWEEN SOLOTHURN AND KRIEGSTETTEN.

To the Editor of "Industries."

Sir,—Having only read the letter of your correspondent "Erg," and not the account of the report of the committee, that appeared in the previous week's issue, I do not know if any reference was made to me personally; but as the designer of the whole plant and the patentee of the machines used, you will no doubt allow me to make a few remarks. In the first place, I may say that I quite agree with your correspondent that if you want an efficient dynamo or motor, you must make it big and heavy enough to do its work. I had to make the Solothurn machines so that they could work continuously the whole day for years, and so that they could in every way compare favourably with steam engines, which, as everyone knows, should

Digitized by Google

work with a margin of reserve power. They can be worked up to 30 h.p. without the heat becoming at all excessive, and the volts increased quite safely up to 1500. Their actual weight with pulley, but without bed plate, is only 58cwt., and not 72cwt., as stated in the report. It must also be borne in mind that the necessity of thickly insulating a high tension machine that shall have a high efficiency must always make it larger and heavier than a low tension machine having the same output. In conclusion I may say I am an Englishman, though a permanent resident here, and, therefore, the difference between English and Swiss practice as shown in this instance is not so great as your correspondent imagines.

Yours, &c.,

C. E. L. Brown.

Oerlikon, near Zurich, 27th January, 1888.

A NEW DEPARTURE IN BRAZING AND WELDING.

To the Editor of "Industries."

Sir,—With reference to Mr. Wildy's remarks, my statement as to the impossibility of welding with ordinary coal gas, referred to its use under the ordinary conditions usually available under the ordinary pressures as supplied from the gas works. Taking the same town's gas service as supplied, without compression, and an ordinary Root's blower for the air, a weld cannot be obtained; whereas if oxygen is used the welding is an easy matter. Under ordinary conditions a gas and air flame, if of high temperature, is always an oxidising one; hence the difficulty referred to.

Yours, &c.,

Thomas Fletcher.

Warrington, 28th January, 1888.

THE LATE MR. JAMES T. CAIRD.

The death of Mr. James Tennent Caird, senior partner of Messrs. Caird & Co., shipbuilders, Greenock, removes one of the pioneers in iron shipbuilding. Mr. Caird was seventy-two years of age, having been born at Thornliebank, near Glasgow, in 1816. Being related to the members of the firm of Caird & Co., he entered their employment as a boy in 1831, but shortly after removed to Glasgow, and to the works of Messrs. Randolph, Cunliff, & Co. His next step was back to Caird & Co.'s, where John Scott Russell was then manager. Mr. Caird became chief draughtsman, and in conjunction with Mr. Scott Russell designed a number of steamships for the Royal Mail Company. On the departure of Mr. Russell for London, where he designed the "Great Eastern," Mr. Caird became manager. Partnership followed, and in 1863 he became sole partner of the concern. Mr. Caird's history is practically that of the firm. Their work for the Peninsular and Oriental Company, the Cunard Company, the Inman Line, the French Compagnie Transatlantique, the North German Lloyd, the Hamburg-American Company, and other well known lines, has placed them in the first rank of shipbuilders. For the Peninsular and Oriental Company alone Messrs. Caird have constructed upwards of twenty vessels, aggregating nearly one hundred thousand tons. Mr. Caird was to the last actively engaged in business, though he had been suffering from heart disease, to which he succumbed while taking a drive in the neighbourhood of Greenock. He was a man of cultivated tastes, and of exceptionally genial temperament.

THE LATE PROFESSOR ASA GRAY.

The scientific world lost an eminent member on Monday last by the death of Professor Asa Gray, the distinguished American botanist. The deceased professor occupied the Chair of Natural History at Harvard College for thirty years, and his scholarship and treatises will cause his name to be ever remembered in conjunction with his contemporaries, Darwin and Hooker. The last visit of Professor Gray to this country was at the time of the meeting of the British Association, held at Manchester last autumn. Everyone who listened to him on that occasion will have reason to regret his death.

University College, Bristol.—On Thursday in last week, Professor Ryan delivered a lecture on steam engineering in the Athenæum Hall, Bristol. The lecturer sketched briefly the history of his subject, noting the various improvements which formed the most important stepping-stones in its course of development. He emphasised the part which Bristol had taken in the development of the applications of steam. Near Bristol, Hornblower's compound engine was first set up. The patents for the use of the crank and fly wheel were held by Wasborough, a Bristol engineer; in Bristol, the Newcomen engine was first applied for mill purposes; and from Bristol the "Great Western" started on its celebrated first journey across the Atlantic. The modern steam engine, in its multiplicity of types and adaptations, was then discussed, characteristic examples being described and illustrated by transparencies. The part played by science in the evolution of the steam engine was dwelt upon, and an appeal on behalf of technical education concluded the lecture.—At a recent meeting of the Engineering Society, the officers for the ensuing term were elected as follows: President, Professor Ryan, M.A., D.Sc., M.Inst.M.E.; Hon. Vice-President, D. C. Selman, Assoc.M.Inst.C.E.; Vice-President, John P. Littleton; Secretary and Treasurer, A. J. Ward; Librarian, C. P. Banham; Committee, Messrs. Dix, Fonseca, Pinto, Ames, Shepherd, and Bruce. A few remarks were made by the secretary upon the satisfactory nature of last term's proceedings, alluding to the successful excursions and interesting papers, animated discussions at the close of each—promising a renewal of the same during the present term. After a few remarks by Professor Ryan the meeting terminated.

SHIPBUILDING NOTES.

Messrs. Russell & Co., shipbuilders, Greenock, recently launched from their yard a steel screw steamer, the "Ocean," for the petroleum bulk carrying trade between America and the Continent. The vessel is 310ft. long, 35ft. beam, and 25ft. depth, and is capable of carrying about 3500 tons of oil. The vessel is divided into sixteen oil tight compartments, exclusive of the water ballast tanks. The tanks have been subjected to exceptionally severe tests before launching, which they stood very satisfactorily. The vessel will be lighted throughout by electricity, and is fitted with a powerful set of Worthington pumps, capable of discharging the entire cargo in twenty-four hours. Triple expansion engines will be supplied by Messrs. Duncan, Stewart, & Co., of Glasgow, the cylinders being 22in., 36in., and 58in. diam., with a stroke of 42in. There are two large single ended boilers, the working pressure being 160lb. The "Ocean" has been built to the order of Messrs. Hermann, Stursberg, & Co., of New York, from the plans and specifications of Messrs. Flannery & Blakiston, consulting engineers, of Water-street, Liverpool, who have also superintended the construction of the vessel. The "Chester," a sister ship to the "Ocean," was launched some weeks ago. The managers in this country for both vessels are Messrs. R. W. Leyland & Co., Liverpool.

An official trial trip of the "Kisanga," a new steamer built for Messrs. Hatton & Cookson, of Liverpool, was made recently, when the vessel attained a speed of thirteen knots per hour, the machinery giving every satisfaction. Her leading dimensions are as follow: Length, 265ft.; breadth, 35ft.; depth of hold, 18½ft.; draught, 14½ft. She has been built by Messrs. John Reid and Co., of Port Glasgow, to the drawings and specification of Mr. G. Hepburn, of Liverpool, and is intended for the African trade. The engines, boilers, and machinery have been supplied by Messrs. David Rollo & Sons, of Liverpool, the engines being of the triple expansion type, with cylinders 25in., 38in., and 62in. diam. respectively, and supplied with steam at a pressure of 160lb. by two steel boilers 12ft. 2in. diam. and 14ft. long, each being fitted with four of Brown's patent ribbed furnaces.

On the 28th January there was launched from the Sunderland Shipbuilding Company's yard, South Docks, Sunderland, the steel screw steamer "C. A. Bade," which has been built to the order of Messrs. Leech, Harrison, and Forwood, of Liverpool. The dimensions are: Length between perpendiculars, 170ft.; breadth, 26ft. 3in.; depth of hold, 12ft. 6in.; and 700 tons gross register. The vessel has a long poop extending over the engine and boiler space, and topgallant forecastle, the latter for crew accommodation. The state rooms, for captain, officers, engineers, and a few passengers, are being fitted up amidships. The steamer has been built under special survey to class 100 A1 at Lloyd's. The engines, which are on the three-crank triple expansion principle, have cylinders 14in., 23in., and 39in. diam.; length of stroke, 27in.; and, together with the boiler, of 160lb. per square inch working pressure, have been constructed by the North-Eastern Marine Engineering Company, Limited, Sunderland. The steam winches are by Messrs. Welford Brothers, Pallion, and the patent windlass by Messrs. Emerson & Walker.

Messrs. Short Brothers, Pallion, Sunderland, launched, on the 30th ult., the steel screw steamer "Diligent," built to the order of Mr. James Westoll & Partners, Sunderland. The vessel is constructed to the 100 A1 class at Lloyd's, on the web frame principle, and has a short poop aft on a long raised quarter deck extending to the after end of the engine and boiler space. A hurricane house extends over the machinery to before the foremast, the crew accommodation being in the fore end instead of in the topgallant forecastle. The double bottom is constructed on the cellular system, and there are four cargo holds, divided with water tight bulkheads. The dimensions of the "Diligent" are: Length over all, 292ft.; length between perpendiculars, 278ft.; extreme breadth, 39ft.; depth of hold, 18ft. 9in.; depth moulded, 21ft. 2in. The vessel is fitted with all the latest improvements for dispatch in loading and discharging cargo. The "Diligent" is the twentieth steamer built by Messrs. Short Brothers for the same owners, and they have another in course of construction. The vessel is to be fitted with engines and boilers of 180 n.h.p., by Mr. John Dickinson, Sunderland, on the triple expansion principle, having three cranks, the shaft being Dickinson's patent. Bremme's valve gear, piston slide valve on the high pressure cylinder, and other improvements have been adopted. The boilers are of Siemens-Martin steel, and work at a pressure of 150lb. per square inch.

The armour plated ship "Victoria," which was launched at Elswick, Newcastle, last March, and which is of similar design and size to the "Sans Pareil," launched by the Thames Iron and Shipbuilding Company a few weeks later, is expected to leave her present position beside the Elswick yard some time in April, when she will proceed to Chatham to be taken in charge by the officials of the Admiralty. Her guns are nearly ready for putting on board, and will be all in position by the time of her departure.

A fine steamer, named the "Rufford Hall," was launched on Tuesday, 31st January, from the yard of Messrs. C. M. Palmer & Co., Jarrow-on-Tyne. This is a sister ship to the "Bremscome Hall," launched on 15th December, 1887, from the same establishment, and also to the "Locksley Hall," launched a few weeks earlier. The vessel, which has accommodation for a limited number of first class passengers, has a carrying capacity of about 6000 tons, and will be employed in the Indian and general trades. Her engines, which are of the modern type, are supplied by the builders. The vessel, like the other two named, has been ordered by Messrs. Alexander, of Liverpool, for the "Hall" line of steamers. Her boats, which are of special strength and beautifully finished, have been supplied by Mr. Wake, of the Low Quay Boat Works, Sunderland.

The "Taroba," steel screw steamer of 5000 tons, was launched on Tuesday by Messrs. A. & J. Inglis, Pointhouse, Glasgow. The "Taroba" is 410ft. long, 46ft. beam, and 31ft. deep. The vessel will be fitted with triple expansion engines of 4000 i.h.p.

Reviews.

The Land Question. By the Right Hon. Lord Herbert and Lady Herbert of Lea. Analysed by Thomas J. Elliot, M.R.A.C., Professor of Estate Management at the Royal Agricultural College, Cirencester. London: Cassell & Co.

We have on several occasions pointed out that in the cry for improved technical education and the necessity for improving what are usually considered industries, we are apt to overlook the oldest and most important industry in the country, that of agriculture. The above mentioned book is issued along with two pamphlets, and with them practically form one work, and Professor Elliot claims that by a careful examination and analysis he has been able to solve the land question in its bearings on agriculture. This analysis is too lengthy for us to reproduce, even in outline; but the student of agriculture will find it well worthy of study, both in its form and materials. The result at which Mr. Elliot arrives, is that even with the present low prices corn can be grown profitably in England; but it is by a system of high farming, for he says: "If you use sufficient capital in farming, you will be able to compete with low prices, and stand safely against a series of bad seasons," and he illustrates this by reference to the Wilton farm of 278 acres, on which the capital employed was £3,500, and the average of twenty-three years' farming has yielded a profit of about 11½ per cent., and he maintains that he proves the fallacy of Sir J. B. Lawes' idea that the reduction in the price of an agricultural crop cannot profitably be met by an increase of the yield; and he tries to disprove the oft-repeated statement that cereals and butchers' meat cannot be produced profitably in Britain at the present low prices. We must leave the discussion on this point to those who are thoroughly acquainted with the details, and we trust they will also consider the possibility of small farms—not so small as crofts usually are, but sufficient to maintain on them a healthy and patriotic race of men.

Technical School and College Buildings. By Edward Cookworthy Robins, F.S.A. London: Whittaker and Co. 1887.

Mr. Robins has done good service to the cause of technical education in revising and re-publishing his various papers on technical school and college buildings, for a well designed building for an educational institution is only second in importance to a well arranged curriculum. It is a comparatively simple matter for those who are taking a part in the work of technical education to make themselves acquainted with the courses of instruction in the different institutions, by a careful study of their calendars or prospectuses, and by a selection of the characteristics suited to the locality in which they live, to draw out a curriculum which embodies the results of a considerable number of institutions. Mr. Robins' book has done for the buildings what a collection of calendars, or better still, a digest of these, would do for the curricula, by bringing as it were into a focus, the results of the experience of many of the best equipped schools and colleges in Britain and the Continent. To managers and governors of technical schools and colleges such a book is indispensable, if they wish to save themselves endless expense and trouble, for in it they are presented with the results of what must have cost a large amount of both.

The author in the first chapter attempts to clear the ground by giving some idea of what technical education means, and illustrates his remarks by the observations he made on the Continent in 1882. The recent debates on the Technical Instruction Bill show that there are still very indistinct ideas as to what is the scope and object of technical education. As Mr. Robins remarks, one enthusiast connects technical education with the development of manual dexterity, another with mental activity and scientific training, a third with a combination of both in one and the same person. One thinks the study of the application of scientific principles to industrial pursuits should precede apprenticeship, another that it should follow it, and a third that it should go on con-

Digitized by Google

currently with it. One thinks our apprenticeship system the best, another the worst, and another denies its present existence and sighs for its resuscitation, or the substitution of something else in its place, neither English nor foreign, but emphatically suited to the needs of the age we live in, and the social peculiarities we represent. One thinks technical education should commence in our primary schools, another in our secondary schools, and a third that every school should have its technical side as sharply developed as its classical proclivities were, are now, and ever shall be. One thinks it is our artisans who are at fault, another their masters, and a third the altered conditions of both; but all are agreed that the maintenance of our acknowledged superiority in technical matters cannot long be continued while we ignore the deficiencies which may exist in our present practice, and complacently shut our eyes to the advantages which other nations are affording to their populations. We have on many occasions given our opinions on the chief points enumerated above, and will often return to them; but we recommend a careful study of the first chapter of Mr. Robins' book for a very good synopsis of the different kinds of answers which have been given to the questions involved, and an outline of the constitutions of the schools and colleges which have been arranged for putting these answers into practice.

The second chapter contains a very useful analysis of the second report of the Royal Commissioners on Technical Education. This report itself has not received the attention which it deserves from the British public, partly we suppose because of the innate dislike of that public to all Blue Books, but chiefly on account of the great length of the report. To many readers of Mr. Robins' book, the contents of that report will to a large extent be unknown, and hence the synopsis which is given of it affords a very useful introduction to the more strictly professional part of the work.

Chapter third is to a great extent a reprint of a paper read by the author before the Royal Institute of British Architects in 1883, and in it is given a description of some of the most interesting and notable of foreign laboratories, illustrated by plans of the principal floors. The author has in this way striven to present to the scientific world, and promoters of similar institutions, the result of much study and travel, which he trusts may issue in the saving of much time and labour, and wasted energy, resulting from going repeatedly over the same ground; and also by his comparative analysis of the best examples, aid in the development of that discriminating power, without which the weaknesses of a design are as likely to be mis-stated as its strong points. We need not go over the list of the various institutions which have been illustrated, but we have much pleasure in noting that the illustrations and descriptions of the new chemical laboratories of the Zurich Polytechnic School, and of the buildings of the Conservatoire des Arts et Metiers, Paris, have been copied from *Industries*, due credit of course being given. We may on some future occasions return the compliment, and give a few of Mr. Robins' illustrations and descriptions.

In the fourth chapter a series of English examples is given, nearly all of which have been completed and opened since the first chapter was written, and, as Mr. Robins remarks, it will be observed that in all these our native independence of character asserts itself in a marked manner, and considerable originality is displayed; the objects sought to be accomplished having generally been attained, at all events wherever the professors and architect have had an opportunity of consulting before the preparation of the plans. The most important institutions illustrated are the Central Institution, South Kensington; the Technical College, Finsbury; the Yorkshire College in its various departments, the Merchant Venturers' School, Bristol; the Mason College, Birmingham; Owens College, Manchester; and various others more or less directly connected with technical instruction.

The next two chapters, the fifth and sixth, although not so generally interesting as the preceding, are almost as important, as they are devoted to the description, analysis, and illustration of the various fittings required to render technical buildings suitable for their educational purposes. The importance of this branch of the subject cannot be too strongly insisted upon, because the fittings are not independent of the structure in science laboratories, but in most cases are an integral part of it, and their suitability or otherwise makes the greatest possible difference in the quantity and also the quality of the work done; and no room or combination of rooms can be said to be properly designed upon the plans of which the whole of the intended fittings have not been arranged before their erection; and Mr. Robins' remarks that if promoters of such projected buildings were to insist upon the association of the architect with the several professors by whom they are to be used, they would save much costly subsequent variation in the plans, which, after all, can never be so perfect as they might have been had previous consultation been enjoined.

In the seventh and eighth chapters the subject of ventilation is very fully discussed and illustrated by a considerable number of examples, all of which will be very useful. The ninth chapter is taken up with middle class school buildings, and examples given of several which the author has designed, and the volume is appropriately concluded by a chapter on sanitary science in its relation to civil architecture. However important technical education may be, we must agree with the author that no subject of study can be more useful and honourable than that of the principles which should govern the direct application of sanitary science to the development of our national architecture—no duty greater than the recognition of our responsibilities in this matter, and of fitting ourselves for it. The growth of contaminating influences injuriously affecting the healthfulness of the elements, the earth upon which we live, the air we breathe, and the water whereof we drink, is commonly the result of culpable ignorance of the simplest sanitary laws, and of the appropriate mechanical appliances necessary to give effect to them. This is generally acknowledged in the abstract, and there are few subjects upon which philanthropists are more ready to expatiate or more reckless in the adoption of any suggestion which sounds sufficiently iconoclastic or revolutionary.

The book is dedicated to Professor Huxley in token of the author's reverence for his genius, and in grateful remembrance of his uniform courtesy and friendly counsel at all times. From the short description we have given of it, it will be evident that it is such a piece of useful thorough work that even Professor Huxley, with all his love of thoroughness, will have no reason to be ashamed of having his name associated with it.

PAPERS: LITERARY, SCIENTIFIC, &c. By the late Fleeming Jenkin, F.R.S., LL.D., Professor of Engineering in the University of Edinburgh. Edited by Sidney Colvin, M.A., and J. A. Ewing, F.R.S. With a memoir by Robert Louis Stevenson. In two volumes. London: LONGMAN, GREEN, & Co. 1887.

The study of the lives and works of scientific men is often of more use to the student than that of formal treatises, for, if these be properly presented, they reveal to us their methods of working and the stages in their mental development. A formal treatise may very often have a narrowing effect on the minds of men who have a tendency to follow precedents closely, and who do not take the trouble to investigate matters for themselves; but if they turn to a record of the life of the man who wrote the treatise, and learn the labour which he bestowed on what appears to be a very insignificant piece of work, they will find an incentive to individual effort and investigation. The recently published "Life and Letters of Charles Darwin" are likely to do more to instil a true scientific spirit into a young student of natural science than all the text books which have been published since Darwin's first work appeared, for in them he will find a record of vast patience and great observing and organising power in certain limited spheres, combined with a simplicity of life and a want of what is usually considered general culture which will alter his ideas of what is necessary to attain to a high position as a scientific man, and to influence thought in all its departments. If he turns from Darwin to Fleeming Jenkin, he may almost find the change too sudden for his mental equilibrium, for then he will be introduced to a man of quite a different type. Instead of slow, patient observation, and careful deduction, he will find a brain of peculiar alertness, and able to attack the most subtle problems in science, or criticise the details of a Greek drama; to lay ocean cables or write stage plays; to lecture on any department of engineering, or to discourse brilliantly in four languages on any subject which turned up in general conversation. And with all this, he was no sciolist; whenever he attacked a subject, he went a considerable depth below the surface. The greater part of the two volumes, as is indicated by the title page, is taken up with Professor Jenkin's papers, the memoir by Mr. Stevenson occupying little more than one-third of the first; but still it will be the first which will receive the greatest attention from general readers. Mr. Stevenson has been sufficiently influenced by the orthodox forms of biography to begin with a chapter on genealogy, and the only point of interest in it to those acquainted with Professor Jenkin is where it shows that, like other distinguished men, he owed the most of his intellectual qualities to his mother, who was a woman remarkable for fortitude, and physical as well as intellectual courage. His father was a naval officer, who had no active service after a comparatively early age, and who, with his wife and son, led a somewhat wandering life. The future professor's first school days were spent at Jedburgh; afterwards he was sent to Edinburgh academy, where he had as contemporaries Clerk Maxwell, and Tait; but the chief part of his education was obtained on the Continent, at Frankfort, Paris, Genoa, all in a very irregular fashion, but which at least had the merit of giving him a good command of modern languages. At the University of Genoa he took the degree of Master of Arts, and there he appears to have obtained his only systematic instruction in physical science, for the University had one of the best appointed physical laboratories of the time. At Genoa, too, he studied art, and made attempts at music, so that his early training affords a key to his whole character, which was a curious combination of French or Italian versatility combined with German or British stability. In 1851 Jenkin returned to England, and began his practical engineering training at Fairbairn's works, at Manchester, where "from half-past eight till six he had to file and chip vigorously in a moleskin suit, and infernally dirty;" but he entered into his work with spirit, for throughout life his principle was, that whatever was worth doing was worth doing well, and he wrote that he "never learned anything, not even standing on his head, but he found a use for it." At Manchester "he was moving daily among those strange creations of man's brain, to some so abhorrent, to him of an interest so inexhaustible, in which iron, water, and fire are made to serve as slaves, now with a tread more powerful than an elephant's, and now with a touch more precise and dainty than a pianist's." But even in Manchester he could not confine himself to mechanical subjects, and for some time he spent three nights a week with Dr. Bell, "working away at certain geometrical methods of getting the Greek architectural proportions," a course of study which was in all likelihood the beginning of that love and intimate appreciation of things Greek, from the least to the greatest. From Fairbairn's and Manchester, Jenkin passed to a railway survey in Switzerland, and thence again to Mr. Penn's, at Greenwich, where he was engaged as draughtsman. There in 1856 we find him in a terribly busy state, finishing up engines for innumerable gunboats for the ensuing campaign. After some time he passed into the service of Messrs. Liddell and Gordon, who had begun to dabble in the new field of marine telegraphy, where he remained for fully two years of very great activity, now in London, now at Birkenhead, fitting out ships, inventing new machinery for new purposes, and dipping into electrical experiment, and now on a telegraph cruise in the Mediterranean. At this time, too, he made the acquaintance of Professor (now Sir William) Thomson, which ripened into the warmest friendship, and had the greatest influence on his future career. They worked together on the Committee on Electrical Standards, they served together at the laying down or the repair of many deep sea cables, and were associated in many valuable inventions and scientific investigations.

In 1859, Jenkin was married to Miss Austin, and shortly after he entered into a general engineering partnership with Mr. Forde, and for some years he had very uphill work in his profession, although his position continued rapidly to improve, not only as a lecturer on various departments of engineering, but also as a practical engineer, and when the Chair of Engineering in Edinburgh University was founded in 1868 he was appointed to it, a position which he occupied till his death in 1885, at the early age of fifty-three. We must refer to Mr. Stevenson's volumes for an account of his Edinburgh life, and for a fuller description of his character, as our remaining space will only allow us to glance at the articles and papers which are reprinted in these volumes. These are thoroughly representative of the man, containing as they do valuable contributions to literature, drama, art, political economy, and science, pure and applied. All except the last of these may be looked upon as the by-labours of a busy life; but they also show much more than taste and appreciation. They reveal a strong individual judgment, which, if not always correct, is always intelligent and suggestive. The papers on "Lucretius and the Atomic Theory," and on "Darwin and the Origin of Species," are especially valuable; and such men as Munro and Darwin have acknowledged the force of his arguments. Like almost all other thinking men he found himself drifting, or being forced into, the study of social and political economy. His paper on trade unions, on supply and demand, all show great grasp of the subjects; and while we may not be prepared to adopt all his conclusions, those on scientific and technical education abound in good sound common sense.

Professor Ewing has selected three papers, each representative in its way, from among Jenkin's technical writings. The first gives in a popular form an account of the scientific development of submarine telegraphy; the second is on "Telpherage," a subject to which the latter years of his life were chiefly devoted, while the third is "On the Application of Graphic Methods to the Determination of the Efficiency of Machinery," and only needs the wider publicity now given to it to make it more appreciated by engineers. The work is concluded by abstracts of "Jenkin's Scientific Papers," and with a list of his British patents, the number of which shows how carefully he must have utilised his time, and taken as a whole gives a very complete view of the professor as a man and as an engineer; and moreover has much intrinsic value.

BACKMAN'S HELICOIDAL LIFT.

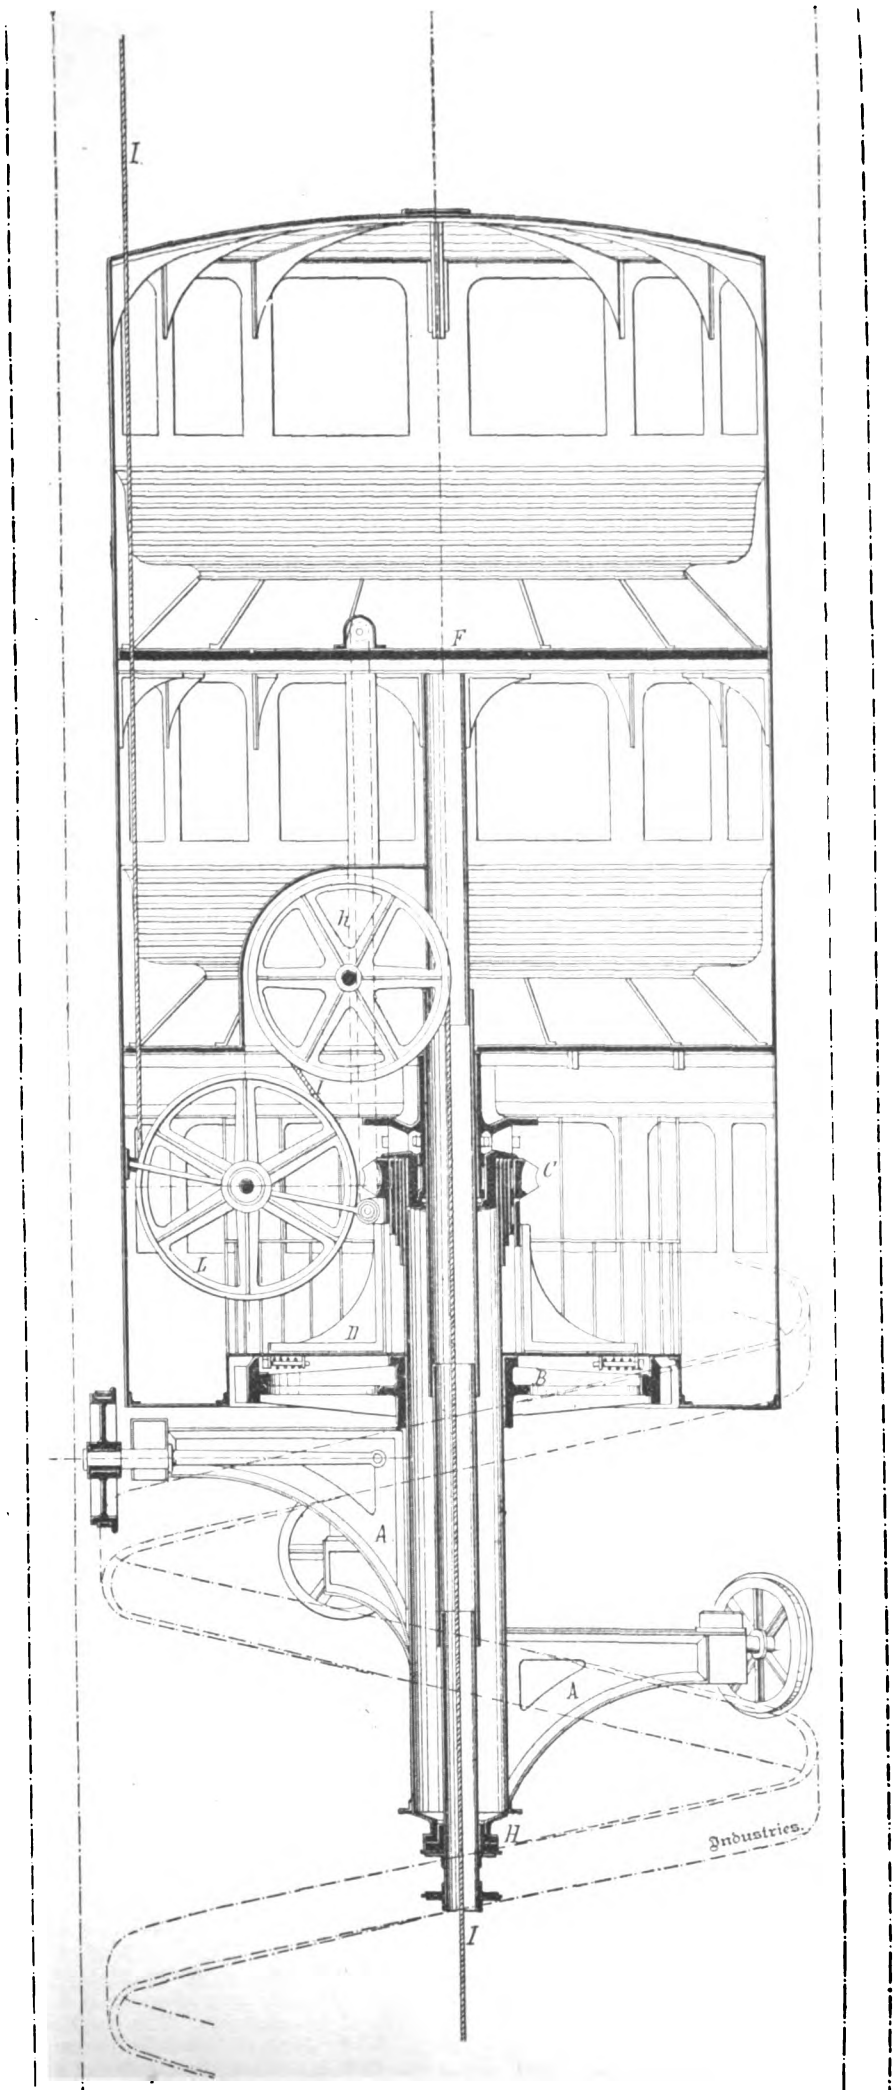

FIG. 1.

BACKMAN'S HELICOIDAL LIFT.

THE immense height of the Eiffel Tower—which is to constitute one of the chief attractions at the great Paris Exhibition in 1889—precludes the employment of any of the ordinary systems of lifts applicable only to moderate elevations. On the other hand, to erect a tower nearly 1000ft. high, and not provide some means for carrying passengers safely up and down, would render the undertaking commercially a failure; for visitors who are necessarily already fatigued with the labour of perambulating the Exhibition proper, will scarcely care to make an ascent as tiring, and perhaps more so, than a climb up a mountain in the Highlands. In fact, most tourists would rather climb a mountain 2000ft. high than walk up a winding staircase to half this height. Some kind of lift is, therefore, an absolute necessity; and as the ordinary winding engine rope and cage would be inadmissible, because not sufficiently safe, a new system has been devised by M. Backman, which has the advantage of being applicable to any height, and yet perfectly safe. Briefly described, the lift consists of a helicoidal railway, on which runs a truck supporting the cage. The truck is revolved on the irons of the helicoid, and thus screws itself up or down, whilst the cage with the passengers, which is placed above the truck, is guided by vertical rods, and participates in the vertical, but not in the rotary movement.

The construction of this apparatus will be clear from the accompanying drawings taken from the *Genie Civil*. Fig. 1 shows a sectional elevation, Fig. 3 the plan of the truck, and Figs. 3 and 4 show details of the mechanism for revolving the truck. The cylindrical cage, which is in two storeys and capable of holding one hundred passengers, is supported on a hollow central tube, which serves as an axis for the larger tube forming part of the revolving truck. The cage is guided between two vertical guides in the shape of riveted plate girders, each supporting a double headed rail as shown in plan (Fig. 4). There are guide pieces sliding against the webs of these rails and rollers running on the heads, these rollers being pressed inward by means of spiral springs *d*. At the lower end of the central tube is a cross piece H (shown in transverse section in Fig. 1), the arms of which are similarly provided with sliding pieces and rollers. The truck consists of the large tube already mentioned, and of five radial arms A (Fig. 3), each carrying a wheel. To insure an equal load to all the five wheels, notwithstanding some slight irregularity which might exist in the helicoidal track, the axes are not rigid, but are pivoted at the inner, and supported on spring washers at the outer end, these spring washers allowing a vertical play of about $\frac{3}{4}$in. The wheels are intended to run at seventy-two revolutions per minute, whilst the truck itself revolves thirteen times a minute. The well of the lift is formed by six vertical lattice girders for the support of the guides and of the helicoidal track. The latter is of rectangular section, and of cast steel strengthened by flanges. The inclination of the spiral is 18° to the horizontal, and the diameter is about 13ft. The vertical guides are placed inside the track, but are interrupted at suitable intervals to allow of the passage of the axes of the wheels. The larger central tube is provided at its upper end with a worm wheel C, and about its middle with a spur wheel B. Power is supplied by an endless rope I running at a speed of 3000ft. per minute, whilst the lift itself travels at about 100ft. per minute. The diameter of the rope is only ·6 of an inch, and to insure a constant tension, notwithstanding possible stretching, it is taken round a weighted pulley at the bottom of the tower. The rope runs in the same direction whether the cage be ascending, descending, or standing still. As will be seen from Fig. 1, the rope, which enters from below through the central tube, is taken within the cage over the pulley *h*, then round the pulley L, and up close to the wall of the cage. The pulley L serves to transmit power to the mechanism, as is illustrated in Figs. 2 and 4. Upon the shaft of this pulley are mounted two loose bevel wheels J and K, which can be coupled to the shaft by means of the friction clutches N and M respectively. These couplings are put in and out of gear alternately by means of two spiral springs and two pairs of levers, the ends of which are controlled by a double right and left handed screw S (Fig. 4). When M is in gear the wheel J communicates motion to the wheel O and pinion P, which gears into the spur wheel B above mentioned. This wheel is keyed to the tube forming the centre of the truck, and the latter is thus caused to rotate in the sense to raise the cage. During the ascent the friction clutch N is out of gear, and the wheels K and Q as well as the worm R and the worm wheel C are standing still. The worm wheel is fastened not directly upon the central tube, but upon a barrel D, which can revolve in one direction only round this tube. On the under side of this barrel there are eight pawls forced out by spiral springs against seventeen ratchet teeth arranged on the inner circumference of the spur wheel B. The inclination of these teeth is such as

Digitized by Google

to allow the spur wheel to rotate whilst the worm wheel is standing; but during the descent the motion is reversed, and one of the pawls engages with one of the teeth, thereby tending to revolve the worm wheel with its barrel round the tube. The worm wheel is allowed to follow this tendency by receiving motion from its worm R in the same direction. The inclination of the teeth in the worm is such that the latter cannot be turned from the worm wheel, and by this arrangement the possibility of the cage descending by gravity alone is excluded, even if the driving rope should break. The worm wheel simply permits the descent as long as the mechanism is in proper working order; but should the rope break or the friction clutches refuse to act, the worm wheel performs the function of a very efficient brake. In addition to this

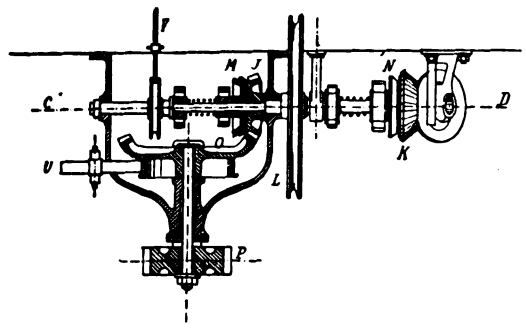

FIG. 2.

there is also a brake V on the shaft of the pulley L, and another brake U on the shaft of the pinion P. It will be seen that by thus sub-dividing the mechanism into two parts, one for the ascent and the other for the descent, it has been possible to employ spur gear for lifting the load, where efficiency is of importance, and worm gear for lowering the load, in which case efficiency is of no importance whatever, and safety is the first consideration. The lift is started, stopped, or reversed by means of a hand chain actuating the screw spindle S, and tappets are fixed at the top and bottom of the lift well, by which the chain is automatically operated at either extremity. The lift will be worked by a steam engine of 120 h.p. placed at the bottom of the tower. In this system the efficiency of the lift is almost independent of the height, and there are no signals whatever required between the cage and the driving engine.

ELECTRIC LIGHTING IN SWITZERLAND.

IT is not surprising in a country like Switzerland, where water power is abundant in almost every locality, that the electric light should be more rapidly introduced than in other countries, where coal is the chief source of power; but probably few English electricians have a just conception of the magnitude of installation work now in progress in Switzerland, with a view to utilise the natural resources of the country for electric illumination and transmission of energy. These large schemes are carried out almost in secret, and very little concerning them finds its way into the scientific or daily press. We have lately given an account of the electric power plant at Solothurn, and we propose in the present article to give a short description of some of the more important electric light and power installations now building in Switzerland, or already completed. The following list is by no means complete, but it is sufficient to show the general tendency of electric lighting in Switzerland, and the manner in which the work is carried out :—

LUCERNE.—The electric light installation at this town has already been briefly mentioned in our columns. Power is supplied by a 300 h.p. turbine, with vertical shaft, fed from a brook, which is a tributary to the river Reuss. The turbine shaft is geared by bevel wheels to a horizontal shaft, from which power is taken by bevel wheels again to two 1800-light self exciting Ganz dynamos, by a pulley and belt to a third Ganz dynamo of the same power, and by another pulley and belt to an Oerlikon continuous current dynamo of 100 h.p., the latter acting as a generator for a transmission plant, the power being given out by an Oerlikon motor installed at a mill near Lucerne. A 200 h.p. steam engine is also provided as reserve, to be used in case of scarcity of water in winter time. At present only one of the three alternate current dynamos is required for lighting purposes; but in summer, when there are many visitors and tourists in Lucerne, two dynamos are used during the evening. All the circuits from the central station are carried overhead across country on poles, and along the streets of Lucerne either on poles or on insulated brackets attached to the houses. At suitable places within the town are installed large transformers of 250 lights each. These are placed in underground localities where possible; but where room within the building could not be obtained the transformer is fixed in a kind of weather proof dovecot on a pole in the street. All the transformers are connected in parallel to the primary circuit, and their secondaries are connected to a network of double lead covered underground distributing mains, through which the subscribers are supplied at 100 volts pressure. The subscribers buy their own lamps, and are at liberty to use the light for as many hours as they please, paying 16s. for every 10 c.p., and 32s. for every 20 c.p. lamp installed. In summer one dynamo only is in use before noon; but in the middle of the day the machinery is stopped for ten minutes to allow a second dynamo to be put into gear, when both dynamos are worked for the rest of the day. Late at night, when the consumption again decreases, one dynamo is thrown out of gear without stopping the machinery, and to provide for this being done with safety an ingenious brake is added to the main shaft, actuated by a centrifugal governor. A sudden increase of speed throws out the weights of the governor and tightens a band brake, which for a short time is able to absorb 100 h.p., thus giving the attendant time to reduce the inlet of water at the turbine. The brake is also useful in case a circuit should be accidentally interrupted, and thus a considerable amount of power be taken suddenly off the shaft. The staff of the station consists of four men in summer and five in winter. Although the work is lighter in the winter time, a larger staff is required to cope with the difficulty of ice. There are no meters in use, but a log book is kept at the station,

BACKMAN'S HELICOIDAL LIFT.

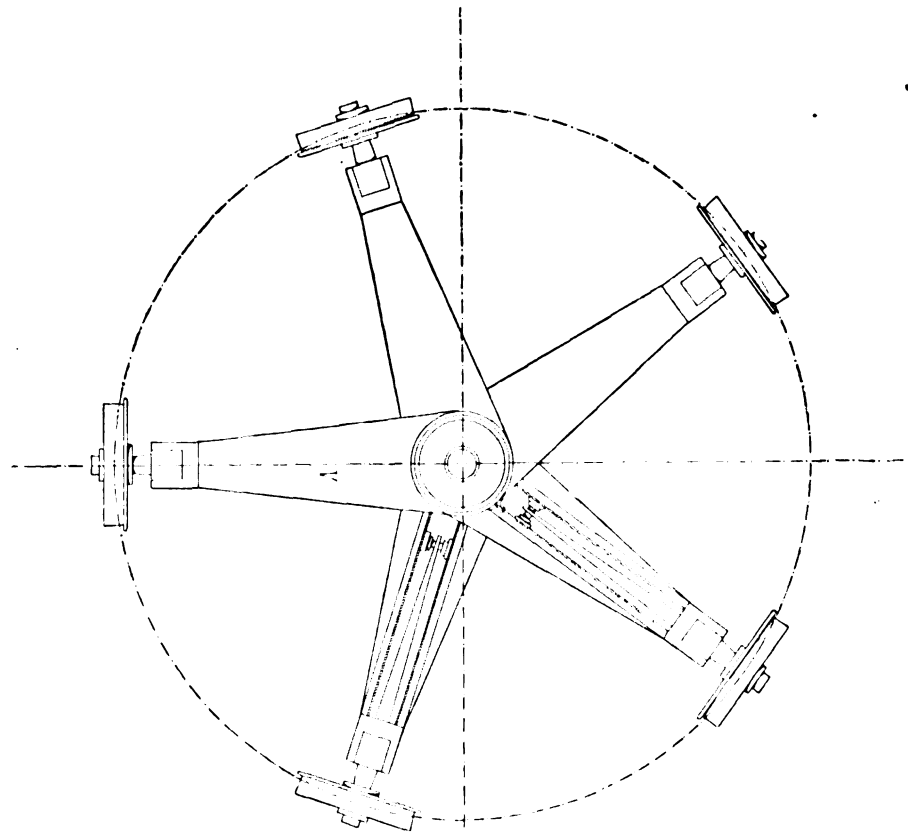

FIG. 3.

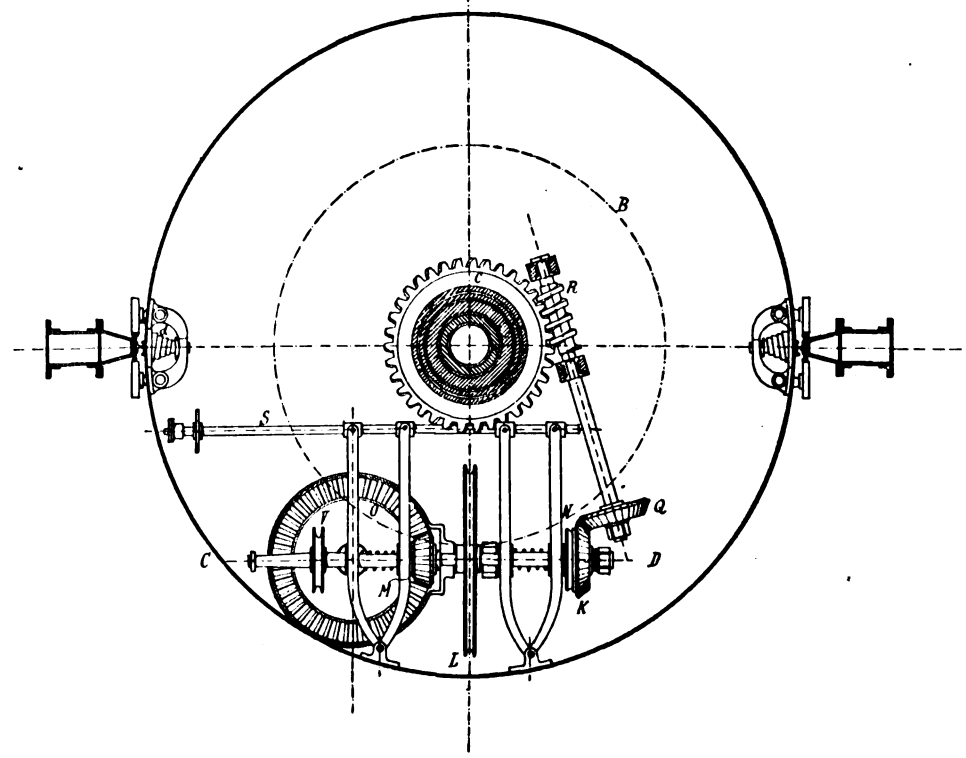

FIG. 4.

Digitized by Google

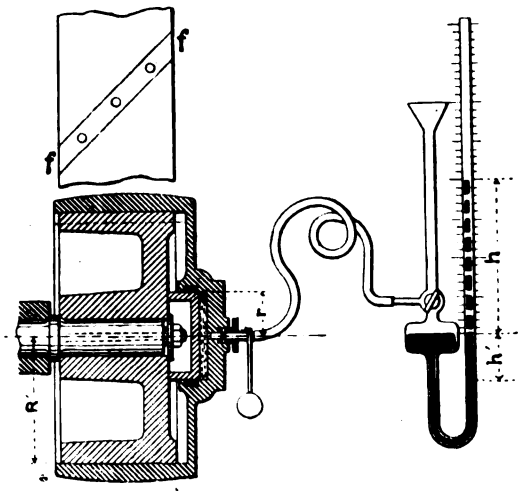
where the current is entered at stated intervals. The potential difference at the points of consumption is kept constant by regulating the speed of the turbine in conformity with the indications of audible and visible signals so arranged as to notify any departure from the normal pressure if this exceeds a certain small limit. The total cost of the central station, including land and buildings, turbine, boilers, steam engine, dynamos, and accessories, but exclusive of distributing plant, was about £16,000.

LAUSANNE.—This town is supplied with water at 12 atmospheres pressure (180lb. per square inch), from a lake lying at a higher level. Although this water is sufficiently pure for domestic use, it is mostly employed for power purposes, there being a second supply of potable water besides. The high pressure supply has been utilised in a small central electric light station, where there are installed three vertical turbines (by vertical we mean wheels revolving on horizontal axes), constructed by F. Duvillard on the Girard principle, with variable admission, and some dynamos, partly Edison machines for 250 lamps each, and speeded at 1100 revolutions, and partly Thury machines for 350 lamps each, and speeded at 500 revolutions. The supply is on the direct system, each dynamo sending current to its own circuit in the town during the evening; but during the day time, when very little current is required, all the circuits are coupled in parallel and served by one dynamo only. The company who own the installation pay 1s. 3½d. per thousand gallons of high pressure water, and as each thousand gallons is equivalent to 1·92 h.p. in falling water exerted for an hour, or say about 1¼ h.p. hour of electrical output, corresponding to 15½ 60-watt lamps, the cost of lighting for power alone amounts to the high figure of about 1d. per lamp hour. There are no Coulomb meters in use, but in some places special clocks are employed which are automatically started by the current as soon as it is switched on, and stopped again when the current is switched off, the clocks therefore acting as lamp-counters. The distributing circuits throughout the town are above ground, consisting partly of naked copper wires on poles, and partly of lead covered cables fastened along the walls of the houses. The light is used in the hospital, and in several hotels and restaurants.

MONTREUX.—The installation for light and power at Montreux is as yet only partially finished; but when completed, it will be the largest of its kind in Switzerland. The current is supplied to Vevey and Montreux for lighting purposes, and also for working the electric tramway between these two places. Water power is obtained from a small mountain torrent called the Baie, which is tapped above Sonzier, a distance of 1000 yards from the central station. As the demand for power in an installation of this kind is only intermittent, it was necessary to accumulate water power during the day for use at night, and an artificial basin, containing about 1½ million gallons, has been erected. From there piping, 16in. diam., of riveted ⅝in. steel plates, is carried to the station lying between 700ft. and 800ft. lower than the reservoir, so that a pressure of about 360lb. to the square inch is available in the mains. The reservoir and conduit cost £1,900. The water is used for actuating vertical Girard turbines, and to avoid breakage of the supply pipe in case the admission valve to any turbine should be closed too abruptly, there are provided two huge air vessels, made of steel boiler plates 40in. diam. by 25ft. high. The whole of the machinery is installed on the ground floor of the stations. There are in all five turbines, which are supplied by branch pipes from the mains situated in the cellar of the building. The main can be shut off by a sluice valve, and each branch pipe is also controlled by a valve. A sluice is also fitted at the intake near the reservoir, and the water from the mains can be run off through waste pipes to prevent bursting of the pipes in very frosty weather. It is, however, not contemplated to run the water off in winter time, except when the cold is very intense. At ordinary winter temperature the water in the pipes will be kept in motion by a small quantity being continually drawn off, whether the turbines are used or not, and by this means it is hoped to prevent accident to the pipes from frost. Considerable difficulty was experienced in making tight connections at the main in the cellar. In the outside conduit the pipes are fitted with steel flanges, riveted and caulked; but in the building the joints are made by screwed flanges, and after several failures to obtain a tight joint, brass rings, with india-rubber packing, were employed, and up to the present have given very little trouble. In addition to the five turbines there are provided two 200 h.p. Sulzer steam engines working direct on to the same shaft as three of the electric light turbines. The two other turbines out of the five are used for power purposes, each actuating a pair of Thury dynamos, the current from which is employed in working the electric tramway already mentioned. The mechanical installation is probably unique, in so far as the two engines and the three turbines all work upon the same shaft, upon which are also mounted the armatures of three Ganz alternate current machines. The whole length of shaft is close upon 65ft., and there are only two couplings in it. When the steam engines are not in use, a portion of the shaft is uncoupled, or the connecting rods taken off. The machines are disposed as follows, beginning at the end of the shaft nearest to the boilers: A 200 h.p. steam engine, a Ganz dynamo for 1800 lights, a 250 h.p. turbine, a 200 h.p. steam engine, a Ganz dynamo similar to the above, a 250 h.p. turbine, another Ganz dynamo for 1800 lights, and a rope pulley at the extreme end of the shaft transmitting motion to a counter shaft, which can be coupled to the shaft of one set of 60 h.p. turbine and pair of Thury dynamos—one on each side of the turbine. The coupling on this shaft is provided so that the Thury machines can be worked either from the main shaft when the water to the turbine is shut off, or by the turbine when the coupling is out of gear. In addition to this, there is another set consisting of a 60 h.p. turbine and a pair of Thury machines as reserve for the tramway. The wheels for the 250 h.p. turbines are contained in casings about 6ft. 6in. in diameter and 20in. wide. They run at 250 revolutions per minute. Steam is supplied to the engines by two boilers of 125 h.p., but space has been reserved for two more boilers. On the main shaft there is also space for some more dynamos and turbines. The boilers, which are worked at 150lb., are fed direct from the high pressure mains; but small feed pumps are supplied in case the water should have to be run out of the main in frosty weather. The steam engines are of short stroke, of very compact design, and intended to run at a speed of 250 revolutions per minute. All the electric distributing mains are placed underground; but the mains supplying current to the electric tramway are carried overhead and arranged in the same manner as on the Frankfort electric railway, that is to say, the conductors are slotted copper tubes in which travel contact shuttles drawn after the car by flexible connections. The tramway passes through Vevey, along the Rue de Samplon, then along the shore of the lake over Bel Air, Maladaire, Clarense, Vernex Montreux, Veytaux to the famous castle of Chillon, the whole length of the tramway being about 5¼ miles. The current is supplied about the middle of the line by four copper wires 285mils. diameter. The overhead conductor is supported on poles in the open, but on brackets from the houses where it passes along the streets. This line is to be opened in a few weeks. At the present moment about 2000 glow lamps have been installed in various shops and restaurants in Montreux, but the company expect to have 7000 installed by the end of the year.

GENEVA.—The central electric light station at Geneva has also been established with a view to utilise the extensive water power now running to waste in the river Rhone as it leaves the lake of Geneva. The employment of this water power for purposes of public utility is not a new feature in Geneva, since water wheels and turbines have for many years been installed for working the pumps which supply the town with water. This installation was, however, on a modest scale, and some ten years ago a scheme was elaborated, by which some 4200 h.p. was to be obtained from the Rhone at a point slightly below the old pumping station. The work was, however, not taken in hand until 1884, and in May, 1886, the new power station was started with six turbines placed in a large house, the turbines developing together 1200 h.p., and space has been provided in the building for fourteen more turbines, which will be gradually installed. Each turbine drives a horizontal three-throw pump, supplying water under a pressure of 750lb. to the square inch, the water being used in the town for motive power purposes. The power is paid for by consumers at the rate of £4. 16s. per horse power per annum, if it is used not longer than ten hours daily. Each turbine is automatically regulated to maintain the pressure in the supply mains constant, and a large air vessel is added to each pump so as to compensate for the slight irregularity of flow in the delivery from the pump. Although this installation has strictly speaking nothing to do with electric lighting, we mention it because owing to its establishment, the old pumping station nearer the town has become available, and a company was formed to utilise this site for the supply of electricity from a central station erected at that place. Up to the present there are erected two vertical turbines of 200 h.p., each directly coupled with two Thury dynamos, whilst a third set of turbine and pair of dynamos is being added. The four dynamos together are able to supply 2600 ampères at a pressure of 140 volts. The lamps installed are 105 volt lamps, and the extra pressure is required to overcome the resistance of the leads. The distribution of the current in the town is intended to be on the three-wire system by underground lead covered cables, and about 3½ miles of mains have been laid down up to the present time. The cables are laid under the surface of the street, and not under that of the footpath as usual. At present the distribution is effected temporarily by two overhead wires, there being only as yet 500 lamps subscribed for; but eventually the installation will comprise at least 6000 lamps fixed. In concluding our rapid sketch of some of the electric light installations in Switzerland, we would draw attention to the fact that the work is practically carried out by means of three types of dynamos, viz., the Thury dynamo for the direct supply at low tension, the Oerlikon dynamo for the transmission of energy at high tension, and the Ganz dynamo for lighting extended districts by means of alternating currents and transformers.

A NEW TRANSMISSION DYNAMOMETER.

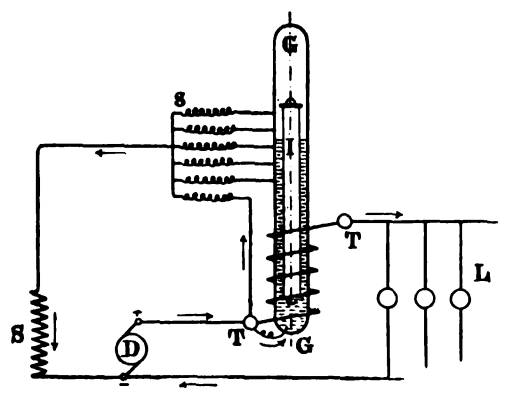


AT a recent meeting of the Berlin Society of Electricians Herr von Hefner-Alteneck read a paper describing a new belt dynamometer, in which the turning couple on the pulley is balanced by hydraulic pressure, and made visible on the mercury column of a gauge fixed against the wall of the dynamo room in any convenient position. The instrument was peculiarly designed for use in dynamos, but is of course also applicable to other power consuming machines. This extremely simple device will easily be understood by reference to the accompanying illustration. The usual pulley of the machine is removed and replaced by a cast iron drum, having a loose cylindrical rim which takes the belt. The rim is connected with the drum by obliquely set feathers *f f*, the inclination being as near as possible 45°. If a turning couple is now applied to the rim and resisted by the drum, the effect will be to slide the former more or less over the latter, and if the inclination of the feathers be exactly 45°, the axial force is exactly equal to the tangential force applied at the circumference of the drum. The sliding in of the rim is resisted by the pressure of some fluid (preferably glycerine) contained in the central chamber, as shown in our illustration. Escape of the fluid inwards is prevented by an ordinary leather packing, such as is used in hydraulic machinery, and its outward pressure is transmitted by a small metal tube with stuffing box to a mercury gauge fixed against the wall. One limb of the mercury gauge is very wide in comparison to the other, so that the variation in the level of the wide limb is only trifling as compared with the height to which the mercury is forced in the narrow limb. The small tube is prevented from turning round under the friction of the stuffing box by a pendant weight as shown. It might at first sight appear that the indication of the mercury column cannot be a true measure of the turning couple applied, because the friction of the feathers between the rim and drum must introduce a considerable error; but Herr von Hefner-Alteneck says in his paper that although when the apparatus is at rest such friction might cause a very considerable error, when the machinery is in motion no ordinary friction will prevent an exact balance being obtained between the turning moment and the hydraulic pressure in the central chamber, the reason being that under the continuous vibration the disturbing influence of friction is eliminated. There are, however, two points which require special attention before the indications of the mercury gauge can be taken as a true measure of the turning moment. It is in the first place necessary to carefully ascertain the diameter of the central chamber, that is to say, the area on which the fluid pressure is exerted and the exact angle under which the feathers are placed. The diameter of the cylindrical chamber can, of course, be callipered with very high accuracy, and to find the angle it is best to scribe on the surface of the drum a line exactly parallel with the shaft, mark a point on the rim coinciding with this line, then turn the rim and measure the distance of advance and rotation on the surface of the drum. If the two be exactly equal the angle of the feathers is 45°; but if, as will generally be the case, they are not equal, a correction must be applied. Let R be the radius in which the pitch of the screw corresponds to an angle of 45° in the feathers, R^1 the radius of the drum, b the length of arc, and a the corresponding advance parallel to the axis, then $R = \frac{a}{b} R^1$.

In calculating the power, this radius must be used instead of the actual radius of the drum. In the next place a correction must be introduced for the variation in hydraulic pressure by centrifugal force as the liquid in the central chamber is being rotated. It is evident that centrifugal force will tend to displace the liquid towards the circumference of this chamber, and thus slightly increase the pressure at the circumference, as compared with that at the centre, from where the indication is taken. The reading of the gauge h is therefore wrong by the amount h^1 due to the sucking action of the centre of the chamber, and this must be allowed for in calculating the power. The mathematical investigation of the influence of centrifugal force is not a difficult matter; but, as it would occupy more space than we can afford, we shall limit ourselves to giving the actual result. Assuming the density of glycerine to be 1·26, and that of mercury 13·55, the inventor finds that the power is expressed by the following formula:—

$$\text{h.p.} = \cdot 594\, R r^2 n\, (h + \cdot 00259\, n^2 r^2).$$

Digitized by Google



The meaning of the symbols used will be clear from the illustrations. The radii are to be given in metres, the gauge in centimetres, and the speed n in revolutions per minute. By making the chamber sufficiently small a very extended scale, with consequently a great degree of

accuracy in the readings, can be obtained. Oscillation of the mercury column, due to irregularity in the driving power of the engine, or inequality in the belt, can be avoided by throttling, more or less, the cock in the pipe which transmits the pressure to the gauge, whilst loss of glycerine can be compensated for by re-filling through the funnel when the apparatus is at rest, or with a force pump when working. The inventor suggests the use of this dynamometer as a permanent accessory to a dynamo room, so that the attendant may at all times see at a glance how much power is being consumed.

AUTOMATIC REGULATION OF DYNAMO MACHINES.

Now that the question of compound winding has been settled entirely in favour of the Brush Corporation, with the result that other dynamo makers have to pay a royalty for the use of the double exciting coils, other methods of making dynamos self regulating for constant potential are sure to receive the attention of manufacturers. In this connection it is interesting to note the method invented by Herr Wilhelm Lahmeyer, of Aix la Chapelle, which is described in our contemporary the *Centralblatt für Elektrotechnik*. Herr Lahmeyer dispenses with the main coils, and obtains regulation by an automatic device for

varying the resistance of the shunt circuit. Our illustration will explain the connections. D is the dynamo, preferably a purely shunt wound machine; S is its exciting coil; s represents a series of parallel resistances through which the exciting current passes; T T are the terminals of the dynamo, and L are the lamps, which may be at any distance. The problem is to keep the pressure at the lamp terminals constant, whilst the number of lamps alight is varied. The more lamps there are burning, the higher must be the pressure kept at the dynamo terminals, and this is done automatically by the simple device represented in our illustration. The main current is taken round the glass tube G, sealed at both ends, and partly filled with mercury, in which an iron core I floats. The shunt current is divided, one part flowing straight up to the first additional resistance s, and the other into the mercury. At the side of the glass tube are fused in platinum wires, connected with the shunt resistances s, and as the main current increases the iron core is sucked down, forcing up the mercury, and thus putting a greater number of these resistances into parallel circuit. By this means the total resistance of the shunt is decreased, and the e.m.f. of the dynamo accordingly increased. It will be noticed that with this arrangement it is quite feasible to obtain constancy of pressure at a considerable distance from the dynamo—that is to say, an ordinary shunt machine can in this way be made equivalent to a machine which is over compounded. The instrument has been in use at the electrical works at Aix la Chapelle and elsewhere for about a year and a half.

Notes.

A STEAM CANOE.

A STEAM canoe has recently been built for the Universities African Mission Society, by Messrs. Simpson and Strickland, of Dartmouth. She has been called the "Nyassa," after the lake on which she is intended for service. Delta metal has been used throughout her construction, and in her details and fittings no expense has been spared. The principal dimensions are: Length, 21ft.; beam, 7ft.; depth, 3ft.; and she draws 16in of water with her engine and boiler on board. On her trial trip she made seven miles an hour with the steam pressure at 100lb., and under sail she attained the speed of six miles an hour.

TRADE WITH SOUTH AMERICA.

GREAT stress is laid upon the importance of consulting the tastes of the South Americans if business is to be done. In a report by a United States Consul in Venezuela, he complains that American manufacturers will not do this, and states that by paying attention to the peculiar requirements of the market the Germans have gained a firm footing in the country. Three-fourths of the foreign mercantile capital in Venezuela is German, and German business houses outnumber those of all other countries combined. The quality of goods sent should be uniform, and the Consul mentions that trade has been partly spoilt owing to shipments of inferior merchandise being made after a profitable business had been established. Personal representation is strongly recommended.

COPPER ALLOYS.

M. G. A. FAURIE has recently announced to the French Academy of Sciences, that he has succeeded in preparing a series of valuable alloys of copper containing varying quantities of silicon. He has found that under suitable conditions an alloy containing 15 parts of silicon per 100 of copper can be obtained. The properties of these alloys are being investigated, as it is found that they vary considerably with their composition. The alloys of copper and silicon prepared by the Hensler process are known to possess great strength and ductility, and wires made from them have greater electric conductivity than ordinary copper wires, and castings made from these alloys are free from pores. M. Faurie's alloys are richer in silicon than those previously prepared in Germany, and the trials of their physical properties are awaited with interest.

TURKEY RED OIL.

THE Turkey red oil used in dyeing Turkey red is obtained by adding concentrated sulphuric acid to crude castor oil. Castor oil, or *oleum ricini*, is mainly composed of the glycerine salts of ricinic, ricinoleic, and ricinstearic acids, and also a small quantity of resinous matter. These substances are readily soluble in rectified spirit and absolute alcohol. The oil is expressed from the seeds of the castor oil plant (*ricinis comricinis*), which contain from 25 to 30 per cent. of the oil. This extraction is done either with or without heating. The "cold drawn" oil obtained in the latter case is of slightly less yellow colour than that obtained when heat is employed. The action of the sulphuric acid upon this oil has been recently studied by Benedikt and Ulzer, who find that the reactions which take place are similar in character to those which are known to occur when olive and other vegetable oils are similarly treated. From their experiments it is inferred that the acid of Turkey red oil is not a true sulpho-acid, but belongs to the class of acids of which ethyl-sulphuric acid is the type. When treated with hydrochloric or sulphuric acid it readily breaks up into sulphuric and oxystearic acids, thus:—

$$\underset{\text{Ricinic acid.}}{C_{18}H_{33}O_2OH} + H_2SO_4 = \underset{\text{Ricinol-sulphuric acid.}}{C_{18}H_{33}O_2OSO_3H} + H_2O \quad (1)$$

$$\underset{\text{Ricinic acid.}}{C_{18}H_{33}O_2OSO_3H} + H_2O = C_{18}H_{33}O_2OH + H_2SO_4 \quad (2)$$

Benedikt and Ulzer have also succeeded in isolating from the crude Turkey red oil prepared from castor oil, a small quantity of crystallised dioxystearic acid. The oils obtained by the action of concentrated sulphuric acid upon olive and cotton seed oil are also used in dyeing, and can be divided into a soluble and an insoluble part, the former consisting of a similar sulphuric ether to that obtained from castor oil, and the latter of oxystearic acid and its anhydride, and also small quantities of oleic acid and unaltered oil.

TOOLS AND IMPLEMENTS FOR CHINA.

IT is pretty well known now that there is little use in attempting to introduce into China tools and agricultural implements such as are in use in European countries, and the United States Consul-General at Shangai states that Chinese mechanics and farmers have strong prejudices in favour of the implements which have been in vogue for centuries. Experiments in placing American tools in the market have signally failed, with the exception of saws, pumps, and certain edged tools. The Consul, however, points out that there is no reason why tools and implements fashioned after their own models should not be imported, as they could be made better and cheaper by machinery than by hand.

THE MANUFACTURE OF GLASS IN CHINA.

A CONSIDERABLE quantity of glassware is turned out by the Chinese in Hong Kong, very inexpensive plant being employed, and the material used generally consisting of old glass re-melted. The United States Consul at Hong Kong states that the crucibles used are small, and rarely exceed 200lb. in capacity. These are set in a stove stoked from a small opening in the side, and about 3cwt. of coal is used in melting one crucible of glass. After being blown the glass is annealed in a small square pit containing ashes and straw, the latter being speedily converted into ash by contact with the heated glass. The moulds used are made of clay, and these, together with a small trowel-shaped iron tool and a few iron tubes, constitute the whole of the appliances used by the native glass blowers.

IMPROVEMENTS IN THE WESTINGHOUSE AUTOMATIC BRAKE.

WE are informed by the Westinghouse Company that they have recently improved the rapid action of their automatic brake to such an extent, that the velocity with which it is applied practically reaches that of sound. From experiments made at the works in Pittsburgh, it was found possible to apply the brakes on fifty vehicles in less than two seconds, the last car being 1900ft. from the engine. The speed of application has thus been considerably increased, in comparison even with the best previous records, in which five seconds were required to communicate the action of the brake from the engine to the last car in a train of fifty cars. The result of this acceleration will probably be to increase the average speed of urban trains, the percentage of time lost in stoppages being reduced.

THE METALLURGY OF BISMUTH.

MR. EDWARD MATTHEY, in a recent communication to the Royal Society, has drawn attention to the fact that metallic bismuth frequently contains a small quantity of copper, which very markedly affects the properties of the metal. The removal of these traces of copper by the usual analytical wet process is a tedious and costly operation; but Mr. Matthey has now succeeded in obtaining from cupreous bismuth the metal in a state of purity by a rapid and simple dry process. The metal is first purified from other metals, such as arsenic, antimony, lead, and tellurium, in the usual way, and is then fused with bismuth sulphide. By this means it is easy to remove all the copper, as the sulphur readily combines with the metallic copper present. Large quantities of alloy can be successfully operated upon, so that it is now possible to obtain commercially pure bismuth, wholly free from copper, from alloys containing ·1 to 1 per cent. of copper.

ELECTRIC SAFETY LAMPS.

MORE than two thousand electric lamps are now in use in the coal mines of this country, and we are informed that miners are in favour of the change, as they benefit considerably by the increased illumination. It is many years ago that it was suggested that our coal mines should be lit by electricity, but the use of portable lamps for this purpose has only recently been introduced. We hope that many companies will see the advantage of this method of illumination over the older and more cumbrous forms of safety lamp, and that an extended use of electricity in our coal mines may be a means of diminishing explosions. There is a disadvantage attending the use of incandescent lamps in mines, inasmuch as they offer no indications of the presence of fire damp. It has been found, however, by Mr. Liveing, that a red hot platinum wire glows more brightly in air contaminated with fire damp than in pure air, and this fact has been recently utilised so as to afford a convenient indicator for the presence of fire damp in mines. As the wire can be heated by the current from the same accumulator as supplies the lamp, no additional energy or expense is incurred, and we learn that from experiments with this apparatus, much better and more reliable indications are afforded of the presence of an explosive mixture than when a Davy safety lamp is the only guide employed.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

20th January, 1888.

877. Ashworth & Ashworth Carding engine cylinders.
878. Matthews, S. ..... Machine tools.
881. Ayres, P. P. ..... Safety apparatus for tram engines.
882. Sinkinson, H. H..... Mules.
884. Skipworth, G. P..... Weighing machines.
885. Otter, J. ..... Crane.
892. Briggs, A. H..... Spinning machinery.
904. Goolden & Atkinson... Method of working coal.
908. Ambjörn, P. (Comte de Sparre)..... Punching jacquard cards.
909. Southall, J..... Gas engines.
912. Purves, D., & others .... Boiler plates.
913. Mallinson & Speight.. Machine for splitting belting.
916. Lockerbie, T. ..... Slide valves.
926. Tomson, W. H..... Freezing machines.

21st January, 1888.

929. Fish, G. H..... Apparatus for forcing liquids.
930. Daltry, T. L..... Looms.
931. Hudson, J..... Washing machines.
934. Clegg, J. C. ..... Lineal measuring and registering blocking machines.
942. Blumrich, M. ..... Hydrocarbon engine.
943. Asbury, J. T. H. ..... Exhausters and pumps.
947. Buckley & Taylor..... Governing steam engines.
952. Tatham, R. .... Carding engines.
960. McGee & McGee..... Thread spooling machines.
972. Goüin, J. ..... Trussed girders.
973. Galloway & Beckwith Steam boilers.

23rd January, 1888.

993. Carter, H. W., & others Machine for charging bottles with aërated water.
998. Thomson, A..... Mechanical stokers.
999. Jones, E. J. ..... Calico printing machines.
1000. Hart, A. C. ..... Trollies.
1011. Bailly, J. B..... Sewing machines.
1014. Goolden & Atkinson .. Machinery for working coal.
1015. Barnes & Tangyes ..... Hydraulic duplex pumping engines.
1019. Robinson & Hanff..... Sewing machines.
1020. Anthon, H. T. ..... Apparatus for manufacturing wood wool.
1022. Tatham, R..... Preparing slivers of cotton.
1028. Carr & Carr..... Cable grips.

24th January, 1888.

1035. Thorp, T. ..... Speed and pressure indicator.
1038. Rankine & Hall..... Boiler furnaces.
1043. Irving, J. ..... Looms.
1053. Beal, W. H. ..... Mangling machines.
1054. Rankine, J..... Furnaces.
1056. Peddie, H. J..... Locomotive steam cut-off.
1074. Mills, B. J. B. ..... Warp machines (*Beer & Co.*).
1080. Lake, H. H. ..... Stop motion spinning machines (*Sanford*).
1081. Granger, A. P..... Crushing machines.
1084. Bintcliffe & Parkins.. Stamping, embossing, and printing in colours.
1087. Orlando, S. ..... Steam boilers.
1106. Stone, R. ..... Machinery for grinding.
1107. Tafel, P. ..... Roller mills.
1110. Leak & Wilson..... Travellers for ring spinning.
1111. White, M. H., & others. Spool finishing machine.
1112. Barbour & Berkeley... Spinning frames.
1113. Thomson, W..... Machines for corking bottles.
1114. Hall, B. G. ..... Digging and intrenching tool.

25th January, 1888.

1115. Douglas, G. C..... Driving gear for roller mangles.
1116. Payne, C. E..... Weighing machines.
1120. Michaelis, E., & others Gig mills.
1121. Tweedale, E. ..... Carding engine.
1123. Moseley, J..... Machinery employed in grinding needles.
1132. Betjemann, S. ..... Hansom cabs.
1137. Hunt, E..... Driving gear for twin screw propellers (*Henry*).
1147. Whitney, A..... Drilling machine.
1153. Greenwood, A..... Machines for the compression of gunpowder.
1160. Davey, H. ..... Steam boilers.
1162. Griffin, E. C. ..... Machinery for pulverising ores.
1168. Bell, T..... Superheating steam (*Niven*).
1170. Lake, H. H. ..... Machines for felting hat bodies (*Waring*).
1171. Dunbar, A. ..... Manufacture of casks.

26th January, 1888.

1179. Guest & Brookes ..... Winding frames.
1185. Monteith, J..... Rotary engines.
1188. Cutlan, J..... Manufacture of boots and shoes.
1191. Coster, J..... Ejectors for breech loading fire arms.
1200. Field, H. ..... Fusible plug for steam boilers.
1204. Walker & Heffer..... Range finding apparatus.
1206. Birks & Cropper ..... Embroidering machines.
1217. Durham, F. W..... Combing and carding machines.
1228. Walker, F. W..... Machinery for loading coals.
1229. Gustavus, Baron de O. Breech loading fire arms (*Fortelka*).
1230. Wolf, G. de..... Furnaces for roasting ores.

ELECTRICITY.

21st January, 1888.

932. Thomas & Warwick ... Batteries.
933. Bosshardt, F. ..... Electric clocks (*Bouchet*).
980. Balch, W..... Battery.
981. Spratt, C..... Electric "call."

23rd January, 1888.

984. Burleigh, W. F. ..... Controlling railway signal levers by electricity.
1009. Davies, J. H..... Dynamo-electric machines.
1016. Taylor, A. M. ..... Electrical transforming apparatus.
1024. Pyke & Barnett..... Electric coils.
1029. Wunderlich, A. ..... Rotary galvanic batteries.

24th January, 1888.

1055. Jones & Wright..... Electric safety apparatus.
1078. Bergmann & Dempster Electrical switches.
1100. Downing, G..... Electrical brazing (*Blass*).
1105. Webster, W..... Treating sewage by electrolytic action.

25th January, 1888.

1128. Fortin, A. A..... Galvanic batteries.
1173. Scheithauer, B. ..... Electric induction apparatus.

26th January, 1888.

1177. Mandeville, E. E. ..... Electric batteries.
1210. Andreoli, E..... Chlorine batteries (*Fichet and Nodon*).

CHEMISTRY.

20th January, 1888.

896. Kenyon, H..... Recovery of sulphur, cyanogen, and ammonia.
920. Overbeck, Baron de G. Production of the alkaline metals (*Hornung & Kassmuyer*).

21st January, 1888.

949. Thornton, J. E. ..... Flash lights for photographic purposes.

24th January, 1888.

1082. Weidig & Remmey ..... Absorption towers for the manufacture of muriatic or nitric acid.

25th January, 1888.

1158. Lennard & Eastick..... Purification of anthracene.
1174. Farquharson and Gubbins ..... Removing the tin from tin scrap.

MISCELLANEOUS.

20th January, 1888.

879. Blakeney, W. H..... Gas and oil burners.
883. Adams, S. H..... Ventilating sewers.
886. Whatley, E. B. ..... Regulating by pass cock.
887. Howard, R. T..... Colliers' picks.
889. Fletcher, A. E. ..... Stoves for heating air.
890. Brett, E. P. ..... Ventilating apparatus.
893. Cadbury & Rollason... Locks and latches.
897. Marshall, J..... Dyeing cotton pile fabrics.
899. Morris, F. S..... Railroad chairs.
903. Putz, F. R..... Material for packing.
911. Gordon, T..... Gas lamps and burners.
914. Fisher, R. H..... Centrifugal beaters.
917. Easthope, A..... Bicycles.
918. Easthope, A..... Velocipedes.
921. Ransome, J. E..... Plough shares.
923. Tighe, C. ..... Fog signalling apparatus.
924–5. Lorrain, J. G..... Recording apparatus.

21st January, 1888.

927. Atwater, H. W. ..... Removable jaw for pipe and bolt wrenches.
928. Spencer, A. ..... Buffers for railway vehicles.
935. Turner, S..... Roof tile.
937. Porri, L. ..... Brake.
940. Muter, D. D..... Printing of colour blocks.
944. Rhodes, O. Y., & others Lamp.
946. Haythornthwaite, W.. Alarm apparatus.
948. Bullen, J..... Mouths of carboys.
950. Andrews, E. B..... Safety doors for hoists.
953. O'Reilly, G. J..... Gas burners.
954. Hart, D. R. ..... Screw drivers.
955. Rainey, C..... Winding bobbins for sewing machines.
958. Armstrong, R..... Railway chairs.
964. Craig, A. M..... Argand gas burners.
967. Wood, A. M..... Rubber compositions.
971. Imray, O. ..... Drawing aerated liquid from reservoirs (*Rowlands*).
977. Ashton, J..... Signalling upon railway trains in motion.
978. Benjamin, H..... Storing water in lifeboats.

23rd January, 1888.

985. Burleigh, W. F. ..... Interlocking apparatus for railways.
988. McNab, A..... Bleaching and washing textile fabrics.
989–90–91–92. Priestley, C. H. ..... Rolling boards for piece goods.
996. Allwood, A. R..... Sewing needles.
1001. Milnes, J..... Warming railway carriages.
1004. Wright, G. A. ..... Brick block or slab for building.
1005. Hunnable, A..... Velocipedes.
1006. Barker & Andrews..... Cartridges.
1007. Stone, J. H. ..... Fittings for hose pipes.
1010. Junge & Junge..... Differential screws.
1013. McEvoy, C. A. ..... Projectiles.
1018. Herzog, C..... Carburetting air and enriching gas.
1021. Davies, A..... Automatic lock.
1023. Holliss, C. P. ..... Axletrees.
1027. Lake, H. H. ..... Permutation locks (*Kromer*).
1031. Pain & Craig ..... Signal lights for use at sea.

24th January, 1888.

1036. Lyon, J. S..... Automatic form of "Clements driver."
1040. Irving, J. ..... Appliance for examining the underside of cloth when being woven.
1045. Rose, G..... Lamps.
1050. Whitehead, G..... Lamps.
1059. East & East..... Taps, valves, and hydrants.
1061. Thompson, W. P..... Valves (*Barnett Brass Co.*).
1063. Cottrell, J..... Velocipedes.
1064. Lindon, H..... Bale band fastenings.
1065. Halliday, C..... Oil lamps.
1066. Dölberg, R. ..... Switches for field railways.
1068–9. Dölberg, A. ..... Joints of rails for field railways.
1071. Bowley, A. S..... Improved clutch.
1072. Cory, E., & others ..... Travelling circular saw benches.
1076. Asher, G. M..... Drawing pens.
1083. Don, A. ..... Consumption of smoke.
1085. Newton, H. E..... Chain bolts (*Cleveland*).
1091. Aird, A..... Counting mechanism.
1092. Simpson, W. S. ..... "Sighting" from torpedo boats.
1093. Edwards, J. ..... Supporting pottery during baking.
1094. Purnell, P. ..... Velocipedes.
1095. Ransome & Garrard... Horse rakes.
1098. Albone, D..... Velocipede.
1101. Wallace & Ward ..... Anti-corrosive compositions for submerged surfaces.
1103. Daley, P. ..... Signals on railway trains.

25th January, 1888.

1109. Prescott, G..... Light giving apparatus.
1117. Masters, J. ..... Circular wire brushes.
1118. Galloway, J. J. ..... Packing for stuffing boxes.
1119. Quick, G..... Cartridges.
1122. Campbell & Pomphrey Manufacture of woven gloves.
1124. Moore, G., & others..... Barrel bolts.
1125. Rogers, S. A..... Cellular rubber sheets.
1126–29. Carter, J. E. ..... Gas heating apparatus (*Böhm*).
1130. Freeman & Bunn..... Alarums.
1134. Kuhnt & Deissler..... Gas burners.
1135. Clery, A. ..... "Metallic cement."
1136. Sargeant, T. C. ..... Belt fastener.
1138. Rankin, A. N. ..... Tools.
1146. Hawke & Ford ..... Apparatus for producing water mark on paper, &c.
1148. Rose, S. J..... Safety bicycle.
1149. Rieth, H. P..... Drying the interior of casks.
1154. Eggiman, A. ..... Hollow tiles.
1156. Grimes & Wakefield... Sight feed lubricators.
1161. Capron, A. J..... Purification of sewage.
1163. Stockheim, H..... Filtering beer.
1165. Schütz, A., & others..... Screws.
1167. Lorenz, W..... Cartridge cases.
1169. Saxby, J., & others ..... Interlocking railway levers.
1175. Arnold, J..... Deodorising sewer gases.

26th January, 1888.

1178. Kennedy, R..... Perforating attachment.
1180. Jevon, A. P. ..... Rack and catch.
1181. Anderson & Anderson. Screw cramp.
1192. Erskin, J..... Lamps.
1195. Williams, J. T..... Treating small anthracite.
1196. Rettie, J., & others .... Utilisation of water power.
1197. Brook & Brook..... Catch for securing corves.
1198. McKenzie, P..... Automatic brake.
1199. Brown, A..... Ventilator.
1202. Bagnall & Heath ..... Railway sleepers.
1203. Jackson, T..... Safety lamp.
1205. Wells, J. S. ..... Warp lace fabrics.
1207. Mills, G. ..... Wet gas meters.
1208. Martins & Rocha ..... Railway switches.
1212. Stevenson, J. ..... Winding bobbin (*Lallemand*).
1214. Werner, J. ..... Gauge glasses for steam boilers.
1216. Truffault, J. M. M.... Tricycles.
1219. Stevens & Cunninghame ..... Velocipedes.
1223. Ibbotson, A. B. ..... Railway buffers.
1226. Gower, S., & others ... Oil lamp.
1232. Gosling, C. H..... Artificial fuel.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

28th January, 1888.

988. Lake, H. H. ..... Reversing steam engines (*Knott and Knott*).
1315. Bergh, W..... Centrifugal apparatus for separating fluids.
1350. Roger, G. ..... Cutting piled fabrics.
1526. Bullough, J..... Grinding carding engine cylinders and flats.
2206–7. Scott, D. ..... Cutting the pile of velvets.
2208. Roger, G. ..... Cutting piled fabrics.
2325. Dorman, W. H..... Circular knitting machines
2585. Catlow, C..... Dobbies for looms.
2923. Kershaw, J..... Machines for cutting mouldings
2953. Hawkins, C. ..... Wind motors.
3750. Copeman, E. S..... Life saving rafts.

Digitized by Google

3964. West, H. J. ..... Refrigerating machines.
3970. Dixon & Simpson..... Cartridge loading machines.
4058. Thompson, J..... Manufacture of paper.
4073. Rogers, H. J. ..... Manufacture of paper.
4117. Cowburn & Peck..... "Taking up motions."
4328. Knox, R..... Propulsion of vessels.
4343. Lambert, T..... Rotary engines.
4361. Wood & Smith..... Cutting steel wire.
4403. Ross & McDowall ..... Rotary engines.
4419. Jardine & Crawley ... Jacquard needles.
4429. Lewis & Hunter..... Shipping coal.
4432. Pilcher, C..... Apparatus for giving first motion to tram cars.
4454. Lister & Carter..... Looms.
4513. Drury & Smith ..... Road vehicles.
4528. Taylor & Struvé ..... Metal plates coated with tin.
4550-1. Daniels, F. H..... Rolling mills.
4595. Lefert, J..... Balancing two wheeled carriages.
4612. Perkins & Cotton ..... Journal for driving shafts.
4663. Thompson, W. P..... Steam engines (*Smith*).
4693. McQuaker, G. W. ..... Pistons.
4799. Binns, C..... Raising yarns, wool, or cotton.
4811. Hawkins, C..... Wind or fluid motors.
5143. Haddan, R. ..... Sewing machines (*Felix Engel*).
5151. Ford-Smith, W. ..... Grinding twist drills.
5672. Woolley, J..... Warp lace machines.
6176. Husband, A., and others Adjusting the pumping load of a Cornish engine.
11186. Brenton, W..... Mowing machines.
12741. Mullins, G. G..... Puddling.
12813-14. Dampier Hickman, J. Rudder attachment.
14400. Sherman, J. ..... Screw propeller.
15626. Kerr & Kerr ..... Wood working machinery.
16405. Fox & Lombard ..... Machines for moulding boot stiffeners.
17384. Boult, A. J. ..... Magazine guns (*Hartley*).
17573. Arnodin & de Palacio. Transporting loads.
17653. Vine, J. W., & others ... Rag tearing machine.
17793. Thompson, W. P..... Apparatus for extracting the juice from cane (*Man*).
17808. Stratton, E. P. ..... Steam separators.

ELECTRICITY.

28th January, 1888.

747. Wynne, F..... Electric motor.
949. Percival, G..... Electrical switch.
2419. Bosshardt, F. ..... Dynamo-electric machines (*Hillaire-Deshois*).
4546. Abel, C. D..... Dynamo-electrical machines (*Siemens & Halske*).
4553. Dickenson, W..... Electric telegraph.
4914. Smillie, R. D. ..... Electric switches.
7530. Statter, J. G..... Electrical transformers.
15858. Main, W. ..... Dynamo-electric machines.
16032. Main, W. ..... Electromotors.

CHEMISTRY.

28th January, 1888.

4201. Taylor, J..... Nitric acid.
4228. Netto, C. ..... Extraction of aluminium.
4241. Baum, H..... Pyro-sulphates.
4397. Walker & Patterson.. Refining sugar.
4430. Brock, J..... Sulphuric acid (*Lunge*).
15265. Thomas, G. ..... Dye matters (*Schulz*).

MISCELLANEOUS.

28th January, 1888.

704. Hall, H. ..... Coating sheets of iron.
2386. Press, W. B. ..... Cistern valves and water taps.
2776. Crastin & Cunningham Lamps.
3027. Tuteur & Goulborne Leather compositions.
3060. Fines, T. W. ..... Swivel and pivot for leather backbands.
3578. Thorpe, J. E. ..... Velocipedes.
3610. Partridge, E..... Clips for axles.
3834. Webb, A. E., & others... Incombustible wicks.
3855. Berg, J. A. ..... Coupling apparatus.
4029. Barton, C. C. ..... Fluid meters.
4067. Onions, J. T. ..... Utilising waste metal tubing.
4161. Rippingille & Rippingille ..... Lamp stoves.
4250. Rylands, D. ..... Bottles for aerated liquids.
4296. Phillips, R. E..... Velocipedes (*Overman*).
4301. Ribbans, E. C..... Petroleum lamps.
4364. Barrow, E. ..... Bale fastenings.
4386. Bordenave, J. ..... Pipes, tubes, and culverts.
4415. Latham, T. ..... Locks and bolts.
4457. Archer & Wilson ..... Relieving the strain upon ropes.
4509. Sutcliffe & Sutcliffe Bleaching and dyeing textile materials.
4512. Marshall, T. ..... Miners' lamps.
4547. Chadwick & Chadwick Dyeing yarns.
4607. Collingham, R. M..... Manufacture of black lead.
4643. Turner & Douglas ..... Snatch or notch blocks.
4796. Low, R. ..... Projectile for throwing lines.
4845. Rössler & Reinhard... Removing roots from malted grain.
4886. Wybauw, J. ..... Heating by means of gas.
4940. Wallwork, R..... Lubricator.
5150. MacNaught & MacNaught..... Scouring and washing wool.
5255. Priestman & Priestman ..... Manufacture of vapour.
6053. Ridgway & Ridgway... Transfer paper.
6203. Alexander, H. McC. ... Spades.
12620. Rofe, S. J..... Locking railway carriages.
13169. Roberts, J. ..... Oil lamps.
13564. Horn, W. W. ..... Nut lock (*Sylvester*).
13779. Emerson & Midgley ... Belting of woven wire.
13896. Boult, A. J. ..... Dyeing of wool tops (*Alexander*).
15396. Brierley, W. ..... Starting of tram cars (*Jeenel*).
16123. Dobson, J. D. ..... Oil lamps.
16797. Boult, A. J. ..... Wire grips (*Evans*).
17042. Cloud, J. W..... Axle boxes.
17237. Drummond, D. ..... Signal alarums on trains.
17392. Davis & Turner ..... Gas burners.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Welding Steel.—*W. B. Middleton, Lancaster, Pennsylvania.*—The inventor proposes to weld pieces of steel together by first applying to them a solution of silicate of soda. The pieces thus treated are then heated and passed through the ordinary welding rolls. One claim is made for this process.—No. 15257. November 8th, 1887. 4*d.*

Warping Machines.—*W. G. Bywater & T. B. Beanland, Leeds.*—The purpose to which this invention is adapted is for winding the warp on each section of the complete warp with the same tension, and so obtaining more perfect uniformity in its building. Fig. 1 is a side elevation, and Fig. 2 a front elevation of the mechanism. The warp is wound on to the section B at a uniform speed by means of the friction plate C and the movable friction pulleys C^1, the movement of the pulleys on the plate corresponding with the movement of the presser pulley C^2, which is operated on by the warp as it is being wound on B. The rollers D draw the warp from the bobbins. A horizontal roller E is supported in bearings E^1, which are fastened to endless chains F carried on chain wheels G. These wheels

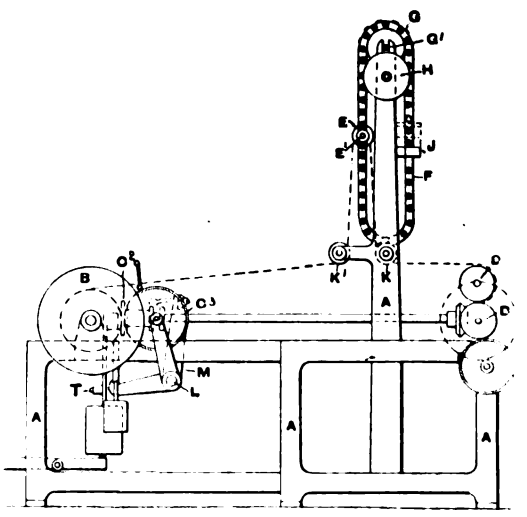

Fig. 1.

are fastened to a shaft G^1, the ends of which rest upon pulleys H. Thus the shaft G^1 is free to revolve, and the chains F and roller E to move up and down. A variable weight J is fastened to each chain. The warp is passed under the roller K, in a vertical direction to the roller E, back again to K^1, and thence to the section B. The warp is subjected to an outward pull between K and K^1, corresponding to the weights J. In order to make the speed of B correspond to that of D, a mechanism is arranged as at L M T. The arm M is fastened to the pressure shaft L, and carries a wheel at its upper extremity; and the other arm, which works loosely on L, is connected to the arm M by a screw, as shown. The other arm

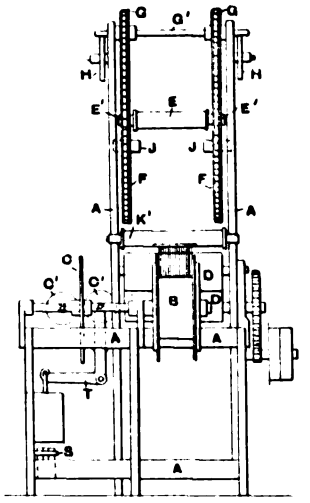

Fig. 2.

also carries a runner stud, engaging between the flanges of the pulleys C^1. By turning the wheel on the arm M, the position of the friction pulleys C^1, on the plate C, may be altered without changing the position of the presser pulley C^2. The inventors claim the application of the movable weighted roller in such a manner as to give a constant uniform tension to the warp.—No. 2140. February 11th, 1887. 8*d.*

Pulverising Machinery.—*W. Boulton, Burslem.*—In accordance with this improvement the machinery is so constructed that the combined effects of centrifugal impulse and impact on the fixed parts of the apparatus shall disintegrate the substance. Through the centre of the feeding hopper extends a vertical shaft, which is driven by a worm gearing at its upper extremity, and which is provided with a series of knives. This shaft and its accessories cause a constant downward feed of the material through a grated bottom, and a lateral delivery of the material which passes through that grating into the pulverising chamber. The upper part of this chamber is made of an eccentric form relatively to the lower part thereof, and is fitted with a removable hard part, which is so disposed that the material flies violently against it on escaping from the limited space between the rapidly rotating arms or beaters and the narrower part of the chamber. The impact thus imparted to the material is effective of pulverisation, and the powder is pressed by the arms through a grating at the bottom of the chamber. The arms or beaters are fastened to a shaft which is driven by a pulley gearing. When hard substances such as flint are operated on, the arms are slotted at their outer ends, and are provided with

Digitized by Google

rollers which carry the material round and exert more force on it. When used for grinding a friable substance, the arms consist of a series of depending fixed studs. The inventor makes three claims for the construction of the rotating parts and the case, and for the feeding motions.—No. 2767. February 22nd, 1887. 8*d*.

Manufacture of Iron Bars from Scraps.—*J. Butler, Neath, Glamorgan.*—The object of this invention is to provide machinery for compressing iron or metal scraps, thick or thin, cold or otherwise, for the manufacture of bars. Fig. 1 represents a longitudinal vertical section, and Fig. 2 a plan of the proposed machine. AA are the boxes in which the bundles of scraps are placed, and B^1 B^2 B^3 B^4 are the four plunger heads which, when brought into

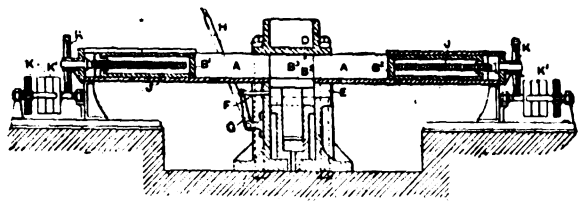

Fig. 1.

position, form the four side walls of the press chamber. B^5 is the lower ram, and E is the aperture through which the compressed blocks are ejected. The ejecting mechanism consists of a sliding bolt F, which is actuated by the lever arm G, and by the hand lever H. The scraps are placed in the receptacles AA, and are driven into the press chamber D by the rams B^1B^2, the ram B^5 being in the position shown in the figures. The motion

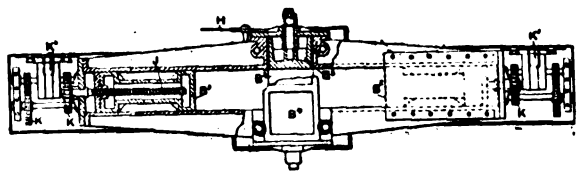

Fig. 2.

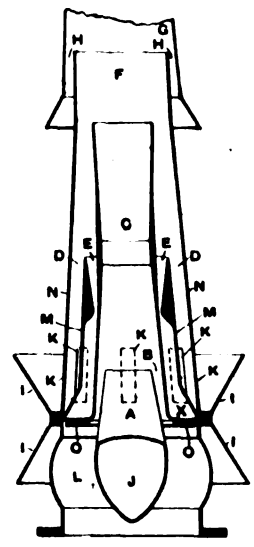
of the rams may be effected by the screws J, which are actuated by double purchase gearing K, and driven by belt pulleys K^1. The rams B^3B^4 then come into operation, whilst the motion of B^1B^2 is arrested, and the final pressure is given by the ram B^5. In withdrawing the resulting block of metal, the ram head B^5 is lowered into the position indicated by the dotted lines in Fig. 1, and the block is carried down with it, the hand lever H is operated, and the sliding bolt F performs the ejectment. It is also allowable to use hydraulic or other power for the compression instead of the screw mechanism made use of in this particular case. The inventor claims the employment of the machinery as described, and the combination of rams and screws, and the arrangement for ejectment.—No. 13560. October 6th, 1887. 8*d*.

Loose Reed Motions.—*H. Preston & J. Bennett, Withnell, and J. Lewis & F. W. Jepson, Blackburn.*—The object of this invention is to simplify the construction of the apparatus used for releasing the reed when the shuttle is trapped or caught in the shed. Attached to the stop rod of the loom are two or more projecting fingers, which, when the slay is forward for the beat up, come opposite to and in contact with projecting lugs on a shaft extending across the loom under the breast beam. A partial rotary motion is imparted to this shaft by the slay swords, so that the lugs are turned opposite the fingers on the stop rod at the time the slay is up for the beat. If the shuttle is caught in the shed, the slay sword will not have operated the cross beam, consequently there is nothing to prevent the reed swinging on its cap, the fingers and the lugs passing clear of one another. One claim is made.—No. 1215. January 26th, 1887. 8*d*.

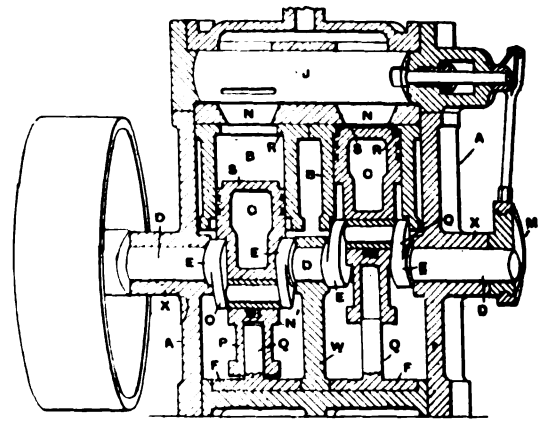


Hydraulic Presses.—*L. R. Bodmer, London.*—According to this invention the hydraulic cylinder and ram are constructed in such a manner as to allow of the renewal of the ram leathers without the removal of the ram from the cylinder. The cylinder is lengthened so as to permit of the ram being lowered from its normal working position sufficiently to expose the leather. A slot is formed in the lower end of the ram, and a stop plate secured to the bottom of the cylinder is formed to fit into the slot. In the normal position of the ram the slot is at right angles to the stop plate; but when the ram is required to be lowered it is turned through a quarter of a revolution, and the slot and stop plate then allow it to sink. A modification consists in raising and lowering the ram from a loose ram top by means of a headed screw spindle screwing into the body of the ram; in this case the slot at the bottom of the ram and the stop plate are dispensed with. The invention also includes a method of removing the damaged leather. A stud which passes through the side of the cylinder is forced inward by a set screw working in a screwed plate; this action presses forward the leather, which can then be removed by a tool. The inventor claims the several ways of lowering the ram for the purpose described, and the method of removing the leathers.—No. 2434. February 16th, 1887. 8*d*.

Smelting Iron Ores.—*H. Gardner, London.* (*R. J. Henderson, Oswego, New York.*)—The object of this invention is to reduce iron ores in such a way as to obtain a malleable metal free from graphite at the first casting. All solid fuel is dispensed with in this process, and the reducing agent employed is pure protoxide of carbon. This gas first reduces the ore, and, afterwards, its combustion with oxygen melts the metal. The apparatus made use of is a form of blast furnace, at the lower end of which are two rows of tuyeres. Into the upper stage of tuyeres carbonic oxide vapour is introduced; the metal produced by this process falls, and is subjected to the action of the blast of oxygen and carbonic oxide from the lower tuyeres, which is sufficient to melt it. The inventor makes four claims for the arrangement of furnace, and for the employment of the particular gaseous agents.—No. 2834. February 23rd, 1887. 8*d*.

Curvilinear Planing Machines.—*B. C. Tilghman & G. Richards, Altrincham, Cheshire.*—The appliance here invented is adapted for combination with a side planing machine, of the kind described in Richards' patent, No. 2260 of 1882. A radius bar is fitted to the machine in such a manner that the tool which is fastened to its end receives its longitudinal motion and cutting force from the overhanging arm, and at the same time the tool is free to slide in the arm, so that it may be made to traverse a curved path by the combination of these motions. The tool post is fastened to the radius bar in a way which allows the tool to retain the proper angle of clearance with the work during the whole stroke. Different degrees of curvature are obtained by varying the distance of the pivot of the radius bar from the tool, and by sliding the radius bar on the pivot box. By giving the radius bar two pivots, which move in slots placed at an angle with each other, the tool may be made to describe ellipses and other curves. The vertical and horizontal feeds may be automatic or given by hand. The inventors make one claim for this combination.—No. 2930. February 25th, 1887. 8*d*.

Shearing Machine for Cutting Hot Blooms.—*J. H. Wicksteed, Leeds.*—This invention relates to vertical shearing machines constructed with a series of live rollers for conveying the bloom from the cogging mill to the shears. The improvement embodied in this invention consists in arranging the face of the shears at 180° relatively with the feed and the delivery rollers, and in feeding the bloom into the shears on the side where there is no obstruction from the fixed bolster. The feeding rollers may therefore be brought close enough to the line of cut to convey into the shears the short remaining piece of the bloom after the longer portion has been severed from it. The roller frame which feeds the bloom is hinged and balanced, so that it will dip as the upper steeling of the vertical shear descends, and recover its level upon its ascent. The gauging stop is disposed on the same side as the fixed bolster, and can be more readily made to reach close to the line of cut when gauging short pieces. Claim: A vertical bloom shearing machine, served by live rollers, in which the bloom is fed into the machine on the side opposite to the fixed bolster.—No. 3340. March 4th, 1887. 8*d*.



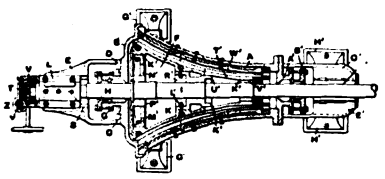
Blast for Locomotives.—*J. V. Smith, Doylestown, Pennsylvania.*—The object of this invention is to prevent the back pressure on the piston caused by the blast, and to secure a means of regulating the draught produced in the flues. The accompanying figure represents a section of one form of apparatus described in the specification. A is the central air passage communicating by induction passages J with the space surrounding the apparatus, B the annular steam space communicating with the steam supply, C the confining flue into which the blast of steam from B is delivered. A confining passage F surrounds this inner ejector A B C, and between C and F is arranged a second ejector, which includes an air inlet D and an annular

steam passage F. The products of both ejectors are delivered into F, whose exit opening is within the third confining chamber G, between which and the flue F a space is formed constituting the air inlet H. The steam issuing through the nozzles B and E operates to draw the air and gases through the passages A and D, and the mixture takes place in the passage F. The tube M is enlarged or tapered at its bottom, and provided with a flange and secured to the base L, and the outer casing N is provided with a series of inlet openings K. The chamber E at its lower end is free from obstruction, and opens directly into the base L; and in like manner the air space D is unobstructed, and opens through the ports K to the space surrounding the apparatus. An annular valve O for regulating the draught is mounted on cams, to which the valve is connected by links, so that when one or more cams are oscillated the valve will be caused to reciprocate laterally and vertically, and will be brought against its seat with a rubbing movement. The valve is prevented from sticking by a mixture of steam and oil, the corrosive nature of this compound being obviated by coating the sliding surface with asbestos or glass. The inventor makes twenty-five claims for the various combinations and modifications.—No. 15573. November 14th, 1887. 11*d*.

Injectors.—*J. Thiry & G. Chantrenne-Soiron, Brussels.*—This invention consists of certain improvements which enable an injector to be brought into operation by a single device. The plug of the steam jet is formed of a conical plug and of a valve. The conical part has an axial bore, and is extended below in the form of a hollow cylinder. The valve slides in this cylindrical portion, and its travel is limited by suitable guides. The valve carries at its forward end a plug of conical form adapted to close the axial bore. The central portion of the valve consists of a toothed rack, and its lower end forms a tongue sliding in a suitable guide in the casing of the injector. A toothed pinion mounted on a shaft operated by a hand lever gears with the rack and gives the required motion to the valve. When the plug is set firmly in the steam nozzle the lever is turned for a short distance, by which means the valve is drawn back and the steam is enabled to pass through the central bore in the plug; when the action of the injector commences the lever is turned further until the valve arrives at its rearward limit in the cylindrical extension of the plug; the continued motion of the lever then draws back the whole of the plug, and the injector attains its full action. The inventors make two claims.—No. 2827. February 23rd, 1887. 8*d*.

Steam Engine.—*D. D. Hardy, Chicago.*—This invention relates to direct acting steam engines, and its special object is the balancing of the parts. The diagram represents an oblique vertical section through the axes of both the cylinders. The two cylinders B are formed in such a way that they may slide horizontally in the casing A. The sliding plates F are connected by pillars and springs with the cylinders, and participate in their motion; and the pistons C take hold of the crank pins directly without the intervention of a connecting rod. The caps N^1 of the pistons carry springs, which press the journal box to the crank pin, thus preventing pounding at high speeds. The caps N^1 are also elongated to contain guides P, which slide

in the standard Q. The simultaneous reciprocations horizontally and vertically of the cylinders and pistons permit of the revolution of the cranks. The springs in the standards which connect the cylinders with the plates F tend to force the cylinders against the surface of the casing, and thus a steam tight joint is maintained between the two. Also the shoulders R are formed in the top of the cylinders to reduce the area of the opening of the cylinders at the ends, thereby producing an upward pressure when steam is in the cylinder, tending to force the cylinder against the casing. The cranks are placed 180° apart, and the weight of the pistons thus balance each other in all positions. The weights of cylinders are to be equal, and also the parts of the pistons above and below the crank pin. The plates F and standards are also proportioned to balance the cylinders. The valve gear consists of an eccentric which causes the cylinder J to oscillate and admit exhaust steam in a well known manner. The inventor makes six claims for the several methods and combinations.—No. 15673. November 15th, 1887. 8*d*.



Utilisation of Iron Stone Waste.—*L. A. Brode, Glasgow.*—The object of this invention is the utilisation of iron stone waste and similar ferruginous material by preparing briquettes of the waste material for use in the smelting furnace. The waste is thoroughly mixed with Armenian bole, which contains a silicated oxide of iron. This mixture is rendered cohesive by a liquor formed by boiling ground rice in water, together with a small quantity of silicate of soda. This plastic mass may then be moulded into briquettes, which are suitable for smelting in an ordinary blast furnace along with the ordinary ore. There is one claim for the process described.—No. 2999. February 26th, 1887. 4*d*.

Boiler Flues.—*E. Earnshaw, sen., E. Earnshaw, jun., & T. Davies, Heywood, Lancashire.*—This invention relates to the flanged circular seamed joints of steam boiler furnaces and flues, and its object is to reduce the liability of the flues to collapse. The two flanged edges, together with the strengthening ring, are to be welded together into a solid joint. The joint thus obtained will be stronger and more perfectly steam tight than the riveted joint hitherto employed, and there will, moreover, be no rivets to get out of order. The inventors make one claim for this construction.—No. 3010. February 26th, 1887. 6*d*.

Hydraulic Motors.—*E. Pombas, Rheims, France.*—This invention relates to mechanism employed in the utilisation of water currents for the propulsion of boats or other purposes. The device is based on a system of four rods arranged in the form of a parallelogram. Let A B C D represent the four rods, A and C being equal and greater than B and D, and generally assuming a vertical position, while the plane of A B C D is always vertical. In one point of its length the rod C is pivoted to the frame work, and the rod A extends downwards to the water, its lower extremity being provided with a float. The arm D is also extended, and forms a connecting rod by being jointed to a crank. The action of the mechanism is begun by the float descending and coming in contact with the current of the water. The float thence obtains a longitudinal motion, which is communicated through the system of rods to the crank. The revolution of the crank supplies the motive power for the purposes mentioned. As the propelling force only strikes the float at one part of its path, it is necessary to have a series of floats and parallelograms arranged in a row, or side by side, in such a manner that no dead points shall occur in the revolution of the propelling shaft on which the cranks are fixed. An adaptation of the mechanism is applicable to the steering of the vessel. The inventor makes three claims for the mechanism and its adaptations.—No. 15786. November 17th, 1887. 8*d*.

Digitized by Google

PULP ENGINES.—*W. W. D. Jeffers, Ticonderoga, New York, U.S.A.*—The inventor's method of constructing and adjusting the grinding rollers is illustrated in the accompanying diagram, which represents a horizontal section of the machine. The rotary grinder F is of conical form, and of separate sections, which are bound together by the bolts L¹. The axle upon which the hub P¹ fits is slightly larger than the part of the shaft upon which R¹ fits, so that the first can be slipped on over the smaller part by shrinkage, and the hub R¹ afterwards similarly fitted and shrunk on. The section T¹ is composed of one piece, and fits upon shoulders U¹. It is confined in its place by a ring V¹, which is shrunk on the part of the shaft which is less in diameter than the other parts. The surface of the grinder is

provided with parallel longitudinal teeth, which co-operate with similar teeth on the removable sections secured in the shell. The adjusting mechanism is supported by the semi-tubular extension E. The end of the shaft is provided with a series of annular grooves, which fit inside similar grooves in the box L. The extension E is provided with longitudinal ways S at each side, in which slide the lateral flanges of the box L so as to guide the box longitudinally as it is moved by the adjusting mechanism. The handle shown in the figure turns the worm wheel, which causes the gear V to revolve. This motion imparts a sliding movement to the box L, and thereby to the shaft I. A wheel Z serves to clamp the worm wheel after the correct adjustment has been made. The inventor makes three claims for the removable sections of the shell, for the grinder, and for the adjustment of the grinder.—No. 15543. November 14th, 1887. 8*d.*

ELECTRICITY.

INDICATING THE SPEED OF SHAFTS.—*R. P. Fuge, Youghal.*—This invention is applicable more particularly to the shafts of marine engines, and serves to indicate the direction and speed of revolution. A dynamo is driven from the shaft by means of belt gearing, and the two poles of the generator are connected with the terminals of the indicating device. This indicator is some instrument such as a voltmeter, which measures the strength of the current generated by the dynamo. The movement of the index on the dial plate of the voltmeter thus indicates the varying speed and direction of the rotation. The inventor makes one claim for this application of generator and indicator.—No. 15977. November 21st, 1887. 6*d.*

DYNAMO-ELECTRIC MACHINES.—*R. E. B. Crompton & J. Swinburne, Chelmsford.*—In dynamos a large proportion of the magnetising force is spent in overcoming the air resistance between the armature and the poles of the field magnet, and when this space has been reduced, the poles often become heated. This invention provides a means for reducing this space, so that a very small magnetic force on the field magnets is necessary to magnetise the armature nearly to saturation. In the case of the cylinder armature in the "Crompton" dynamo, a space is allowed between the outside of the armature and the pole pieces sufficient to admit of the requisite amount of wire being wound on. In this invention the field magnets are relatively small, and the wire is not wound on the outside of the armature, but passes through holes which are punched through the discs near the outside edges. These holes are punched at such distances apart that there is enough section of iron remaining to admit of the induction due to the field magnets. Another form of machine made according to this invention is a ring armature of square section. The field magnets take the form of thick slabs, which cross the sides of the ring so that the axle goes through the centre of the magnets. In this case the wire of the armature passes through holes bored radially in the ring. The wire that comes out at one hole passes round the periphery of the ring, and then passes in at another hole, crossing over inside to the first hole again, and so on. This invention is also applicable to a very large number of types of armatures. The inventors make ten claims. —No. 17120. December 31st, 1886. 8*d.*

INDICATING SPEEDS AT A DISTANCE.—*J. G. Statter, London.*—The object of this invention is to improve the apparatus for determining speeds, which consists of a transmitter and an indicator connected by an electric circuit and battery. The invention is based on the fact that when a dynamo-electric machine is run at varying speeds on an open circuit, it generates a current whose electromotive force varies with the angular velocity of the armature. The speed of rotation can thus be indicated by measuring the electromotive force. The shaft whose rate of revolution is required to be ascertained is coupled by belt gearing to a dynamo, and the current thereby generated is led by a circuit to a voltmeter, which serves to indicate the electromotive force and hence the speed of the revolving piece. By this method the closing push operated by hand and the winding up of the springs are dispensed with. The inventor makes three claims for the application and combination of the dynamo and voltmeter for the purpose described.—No. 2990. February 25th, 1887. 6*d.*

CHEMISTRY.

EXTRACTION OF GOLD FROM ORES.—*C. T. J. Vautin, London.*—The invention here described consists of improvements in the process and apparatus described in the specification of Patent No. 4609 of 1887, granted to the same patentee, in conjunction with J. C. Newbery. The pulverised auriferous material is treated with chlorine, applied as gas or in solution, under a pressure greater than that of the atmosphere. This process is carried out in a closed chamber, which is caused to agitate its contents by rotation. The chamber is connected with an air force pump, and is otherwise capable of being hermetically sealed. After the material has been exposed sufficiently to the action of the chlorine solution the chamber is tipped, and its contents emptied into a filtering vessel. Here the auriferous solution is drawn through the filtering medium by means of suction produced by a suction pump, which is so constructed as to produce in every stroke a partial reflux through the filtering medium of the withdrawn liquid charge. The filtering medium is thus cleansed and kept free from choking. From the suction pump the auriferous solution is discharged into a suitable vat, through which air or steam is passed, and afterwards is allowed to penetrate successive beds of charcoal. The solution is here rapidly decomposed, and the gold is deposited on the charcoal. The inventor makes six claims for the combination of air compressor and hermetically sealed rotating vessel, with the filtering vessel and reflux suction pump, and the beds of charcoal, as described.—No. 15574. November 14th, 1887. 8*d.*

KIESELGUHR DYNAMITE.—*E. Grüne, Unterlüss, Hanover.*—When kieselguhr dynamite comes in contact with water, the nitroglycerine is violently expelled from the kieselguhr. In order to obviate the inconvenience and danger arising from this circumstance, the inventor mixes certain quantities of vegetable or animal carbon with the kieselguhr, or carbonises such substances as starch, sugar, glue, &c., in kieselguhr. It is found that this mixture is not affected by its contact with water, and that the frozen cartridges may be thawed in warm water. It is possible with kieselguhr carbon to blast under water without surrounding the cartridges with any case, and the loaded blast holes may be rammed with water. There is one claim.—No. 16116. November 23rd, 1887. 4d.

FLUORIDES OF MAGNESIUM, STRONTIUM, AND BARIUM.—*A. Feldmann, Hanover.*—The production of these fluorides is effected by treating the chlorides with the fluoride of calcium during the application of heat. The process may be carried out in either the dry or wet way. Instead of using the anhydrous chloride of magnesium, it is more economical to employ the double chloride of magnesium and potassium. The inventor makes two claims for the dry and wet process respectively.—No. 15295. November 9th, 1887. 4*d.*

MISCELLANEOUS.

PULSOMETERS.—*A. G. Brookes, London.* (*M. Greeven & Co., Düsseldorf.*)—The first part of this invention relates to the valves of the steam vacuum pumps known as pulsometers. Fig. 1 represents a vertical section taken through the pump chambers P. The valves L I are fitted in the cases L¹ I¹ respectively, and the lever J has at each end a link J¹, which

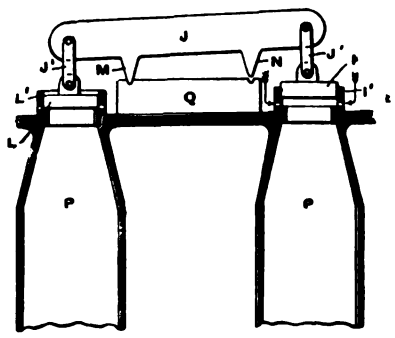


FIG. 1.

serves to lift and lower the valve. Two pegs M N are provided on the under side of the lever J, and they alternately act as fulcrums for the lever whilst it lifts the valve L or I. The second part of the invention is connected with the main forcing chamber of pulsometers. The liquid is first caused to pass through a forcing chamber worked by steam before entering the pump chamber. Fig. 2 shows an arrangement of parts designed in accordance with this invention. A is the first chamber and B the pump chamber, C the suction pipe, D the valve to the suction pipe C, and E the valve controlling the

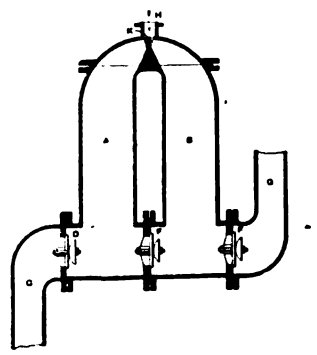

FIG. 2.

passage of communication for the pumped liquid between the chambers A and B. The valve F controls the passage of liquid through the discharge pipe G, and H supplies the steam for forcing and condensation; K is the valve for distributing the steam. If the chambers A B are filled with water, and if K be in the position shown, the water will first be driven by the steam from the chamber B into G until the condensation takes place. The valve K then changes its position, and the steam is allowed to force the water from A into B. When the condensation takes place in A, the valve K changes position again and opens communication afresh with B, and the water is forced into the discharge pipe G, whilst A receives a fresh supply of water through C. This completes the cycle of operations. The inventor claims: (1) The rocking lever; (2) the parts and combinations of parts of the lever; and (3) the arrangement of the chambers A and B.—No. 3151. March 1st, 1887. 8*d.*

WASHING TEXTILE FABRICS.—*E. B. Petrie, Rochdale, & R. Wild, Littleborough.*—This invention consists of the manufacture of a mixture for washing and scouring all sorts of textile fabrics. This mixture is composed of sub-borate of soda, soda ash, chloride of soda, soap, phosphate of soda, caustic soda, and hyposulphite of soda, in certain proportions. In the bleaching process the inventors make use of a somewhat similar mixture; and modifications are introduced into the composition of the mixtures, to adapt them for household use. Four claims are made.—No. 7550. May 25th, 1887. 6*d.*

SPINNING MACHINERY.—*T. Bentley & S. Makin, Oldham.*—This invention relates to improvements in apparatus described in Patent No. 5319 of 1883, and has for its object the simplification of the said apparatus and the counterbalancing of certain parts in order to reduce the strain on the sliver yarns. In the accompanying drawings, Fig. 1 is a cross section of part of a

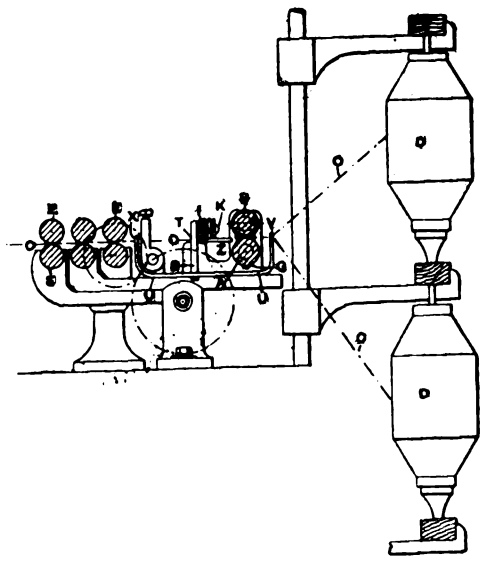

FIG. 1.

slubbing frame, and Fig. 2 is a plan view of the same machine on a larger scale. A shaft A supports another roller B, and between these two the sliver yarns pass as they come from the bobbins D. Longitudinal projections G are formed upon the periphery of the roller A, and to accommodate such projections the roller B is reduced in diameter where necessary. The extensions Y and Z of the arms I thereby permit of shortening. For the counterbalancing of these arms I, two sets of such arms are now employed, and are mounted upon a single stud K at the back of the bars T. Instead of bars extending the length

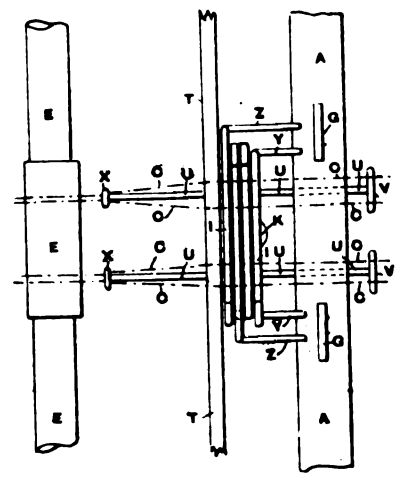

FIG. 2.

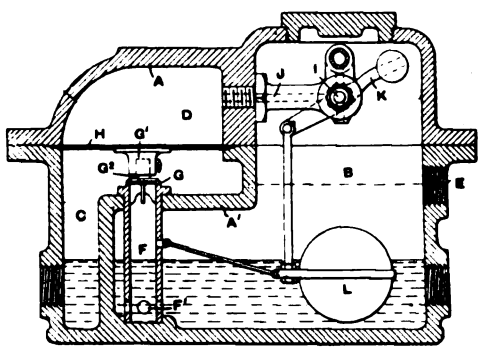
of the frame behind the drawing rollers, the inventors substitute a bracket S, secured to the under side of the remaining bar T and provided with a pair of arms U, one projecting backwards to the rear of the shaft A, and there provided with a pair of eyelets V to receive the two separate yarns C, and the other projecting forwards and provided with a single hole X to conduct the two sliver yarns together to the drawing rollers E. The inventors make three claims, for the longitudinal projections on the back roller, for the counterbalanced arms, for the arrangement of the bracket and eyelets, as described.—No. 4674. March 29th, 1887. 8*d.*



REFRIGERATING MACHINES.—*A. Conacher, Augusta, Georgia, U.S.A.*—These improvements refer to refrigerating machines, in which cold is obtained by exposing water to a high vacuum, and by passing the vapour from the water over the surface of sulphuric acid, as described in Provisional Specification No. 1181 of 1887. The acid vessel is made of iron, provided with an inner coating of enamel or aluminium. A furnace is placed beneath this vessel for the concentration of the acid after it has been weakened by the watery vapour. The vessel is so arranged that the acid is never removed from its container for the purpose of

Digitized by Google

re-concentration, and one supply of acid may thus be used for a considerable time. The acid is divided by a central partition, to assist in the agitation of the acid during the absorption of the water, and to prevent the formation of a thick upper layer of weak acid, which would retard the freezing operation. Pipes connect the two divisions of the liquid, and are placed in a slanting direction away from the partition; they are closed at their ends, and are provided with perforations, so that when one end of the vessel is raised the acid from the lower part of the raised end may be carried up into the other compartment, and through the perforations drop on to the surface of the upper layer of acid in that compartment. At each end of the vessel are domes, which are the continuations of the vessel, by which flexible pipes are connected with the pump and freezing vessel respectively. The pump is fixed to the upper part of the framing of the machine, and the acid vessel is underneath the pump. The valve plate is formed with annular apertures, and intermediate grooves, so as to reduce the bearing surface of the valve disc thereon. The inventor makes three claims: For the coating of the acid vessel, for the application of the rocking acid vessels to refrigerating machines, and for the construction of the rocking vessels.—No. 2319. February 14th, 1887. 8*d*.

Manufacture of Textile Threads.—*A. M. Clark, London.* (*M. P. E. Gérard, Paris.*)—In producing textile threads from viscous and pasty materials, such as gelatine, by forcing them through holes in a cylinder, the chief difficulties to be overcome are the agglomeration of the material round the orifice and the disinclination of the material to coagulate after the operation. The present invention has for its object the obviation of these hindering circumstances. The medium in which the operation is conducted is to be water or some gas depending on the nature of the material. The substances which the inventor more particularly makes use of are those which have a base of gelatine and gun cotton. The medium in this case may be superheated steam or ammonia. The inventor makes three claims: (1) For the general process of using a gaseous medium for the purpose described; (2) for the application of superheated steam; and (3) for the use of ammonia as described.—No 2695. February 21st, 1887. 6*d*.

Steam Traps.—*P. Fyfe, Glasgow.*—This improvement renders steam traps intermittent in action as regards the discharge of the accumulating water. A longitudinal vertical section is shown in the figure. The casing A is divided by means of a web A¹ and a disc H into three compartments B C D. To the main compartment B, the water and steam from the vessel to be drained is admitted by an inlet E, while the compartment C serves as an outlet for the water discharged from B; the compartment D is intermittently and automatically placed in communication with the steam space of B. A tube F extends into

the compartment C, and forms the seating for a valve G, through which the water is discharged from B when at a sufficient height. Upon the admission of steam to the vessel D, the disc H bears down on a flanged piece G¹, screwed to the upper end of the valve spindle G², and thereby closes the valve, whilst upon discharge of the steam from the compartment D, the pressure is relieved, and the valve is raised by the steam above the water in B. The alternate admission to and discharge from D is effected by a three-way cock I, placed in the pipe J, which forms the connection between B and D. The lever K and float L serve to operate the cock. When the water level in the trap is low, and the float in the position in the figure, the chambers B and D are connected by the pipe J. When the water rises to the dotted level, the cock is turned into a position which closes communication between B and D, and opens D to the atmosphere by means of another tube connected to the cock I. The pressure on H is thus relieved, and the valve G is opened, and the water forced out of the trap until the level is reached at which the float turns the cock to its previous position. The inventor claims the combination of discharge valve, pressure chamber D, diaphragm, three-way cock, and float.—No. 15345. November 10th, 1887. 6*d*.

Refrigerating Materials.—*G. Downing, London.* (*H. T. Baeschlin, Montpellier, France.*)—The refrigerating materials are manufactured in a form so that they may be kept ready for use at any time. A non-conducting absorbent substance, such as cotton wadding, felt, jute, &c., is caused to absorb by pressure a mixture of refrigerating salts, for example, ammonium nitrate or sal ammoniac. The crystals of these salts may be either produced within the fibres after the latter have been immersed in a solution of the salts, or several layers of the material may be impregnated with solutions and the water subsequently evaporated. In the latter case the crystals assume the form of a crust, which is then distributed uniformly by means of mechanical pressure. In applying these refrigerating materials medically, one side of the compress is wetted. The imbibed water gradually penetrates the material, producing a continually increasing cooling action. The inventor suggests the advantage of a comparatively dry cooling process here obtained over the usual method by the application of ice; and a perfectly dry cooling effect may be produced by the interposition of an impermeable fabric. There are two claims.—No. 3843. March 14th, 1887. 6*d*.

GERMAN PATENT ABSTRACTS.

Safety Lamp.—*Julius Jaff, Vienna.*—This invention relates to the improvement of safety lamps for miners. The sides and upper parts of the wire gauze D are provided with a cover E, made by coiling a string of hollow iron or steel beads A round D. This string is shown in Fig. 2. The object of this cover is

Fig. 1.

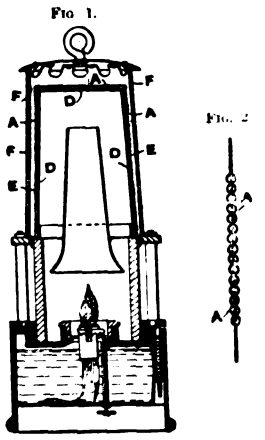


Fig. 2

to prevent the flame of an explosion inside the lamp from being communicated to the surrounding gases. The access of air to the inside of the lamp can be prevented by shutting the slides F.—No. 41755. May 21st, 1887.

Compressors.—*C. Hasemann, Berlin.*—This invention relates to an automatic valve gear for compressors. The inventor uses slide valves, which are adjusted by means of a link. The difference of pressure of the compressed air in the valve casing, and

Fig. 1.

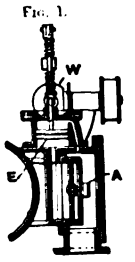

Fig. 2

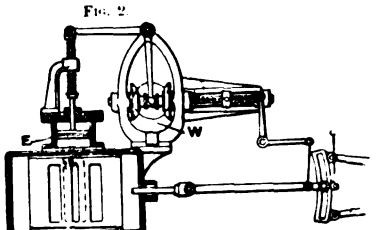

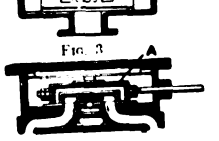

Fig. 3

in the cylinder, is used for moving the piston E, which actuates the slide valve A, thereby regulating the degree of compression. In small compressors the motion of E is directly communicated to A, but in larger machines a gearing W driven by an engine, and a combination of levers, is arranged for that purpose.—No. 41681. March 8th, 1887.

UNITED STATES PATENT ABSTRACTS.

Manure Distributor.—*M. P. Faris & H. A. Falls, Bethany, South Carolina.*—This apparatus is in the form of a wheelbarrow upon three wheels. The hopper in which the manure is placed has one of its ends made adjustable, so as to regulate the rate of distribution. The two large wheels are connected by an axle, which passes through the hopper near its bottom. The axle carries a central distributing wheel, which consists of a series of radial knives fastened to the axle. As the carrying wheels rotate, the central wheel feeds the manure out of the hopper on to the ground.—No. 375807, dated 3rd January, 1888.

Hinge.—*F. P. Bailey, Indianapolis.*—The hinge is composed of two end plates, which are fastened to the ends of the two pieces of wood to be jointed. The corners of these plates, which form the centre of rotation, are rounded off, and in each plate is a pivot pin. A link is pivoted to the plates by means of these pins, and other pins one in each plate slide in circular slots which are formed in the link concentrically with the pivot pins. This method of forming the hinge tends to reduce lateral strains in the screws which hold the plates to the wood.—No. 375792, dated 3rd January, 1888.

Harvesters.—*L. Miller, Akron, Ohio.*—The modifications in the self binding harvesters introduced by this invention include a needle arranged to operate in a vertical plane oblique to the grain carrier movement, a system of packers whose path of motion is oblique to that of the grain delivering apparatus, and a mechanism for turning the grain and delivering it to the packers. Other parts made use of in this machine are described in the specifications of Patents No. 276448, 290459, and 293345. There are twenty-two claims.—No. 371698, dated 18th October, 1887.

Fish Trap.—*J. Brosch, St. Louis.*—This invention consists of an illuminated bait receptacle for submergence in water. A lamp is encased in a water tight glass globe, and two vertical concentric chimneys rise up over the globe for the purpose of supplying air to the lamp, and of taking away the products of combustion. Outside the lamp globe is another transparent casing, between which and the globe is suspended the bait. This apparatus is designed for use in the night fishing industries. The inventor makes six claims for the combinations.—No. 373333, dated 15th November, 1887.

Machine for Screw Threading Tubes.—*A. Saunders, Yonkers, New York.*—Fig. 1 represents a partial sectional view of the machine embracing this invention, and Fig. 2 shows a vertical transverse section, in a plane at right angles to that of Fig. 1. In the standards C are horizontal grooves C¹, in which are fitted the splines D¹. These splines are on the side of the cage D, which carries a chuck. The tube to be operated on is placed within the sleeve B¹, which is shown in Fig. 2. The vertical guides F² fit into grooves in the edge of a frame E, which holds the upper and lower gripping jaws E¹ and E² of a gripping chuck. The upper jaw E¹ is suspended by a screw A², which extends downwards through the central space of a double nut. The screw bolt I¹ is turned by a hand lever passing through its head, and the revolution of this screw tends to raise the frame E and the jaw E², and at the same time to lower the jaw E¹ in the frame. This mechanism is intended to improve the method of gripping the tube. The externally threaded sleeve B¹ extends forward into the rearmost part of a sleeve F, which is provided on the rearmost side of a face plate F¹. At the inner

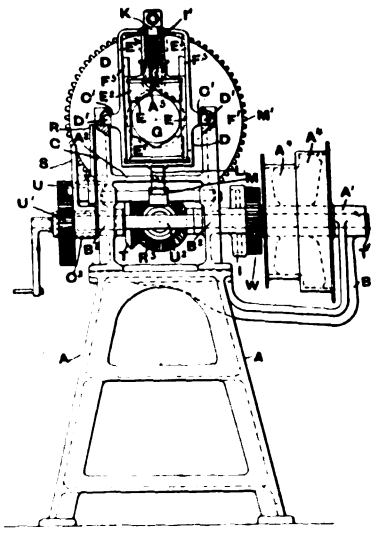

Fig. 1.

end of the sleeve F are rectangular sockets, in which are placed the parts of a sectional nut H¹. The inner surfaces of the sections are threaded to act in connection with the screw thread of the sleeve B¹, and are fastened by means of bolts to the cam ring G, which may be turned round the axis of the tube by a lever. The rotation of the cam ring depresses the nut sections, and makes them gear with the thread B², and thereby enables the sleeve B¹, together with the chuck, to be moved inward or outward by the rotation of the sleeve F. The tube to be operated on being thrust between the chuck jaws, and any suitable screw threading mechanism being secured upon the

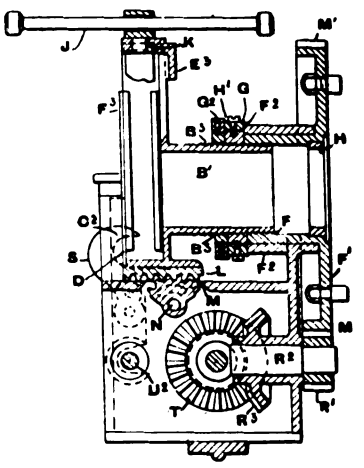

Fig. 2.

face plate F¹, the rotation of the face plate F¹ causes the nut sections to feed the sleeve B¹, and, consequently, the tube to be threaded. The motion of the face plate is communicated to it by the cogs M¹, which gear with shaft R¹, and the gearing R² R³ T T¹ drives this shaft. In order to move the sleeve B¹ inward or outward, the rack L is provided at the bottom of the cage D, gearing into a toothed quadrant M, the shaft N of which carries an operating lever R. The shaft may thus be rocked, and its motion causes the longitudinal movement of the sleeve B¹. The inventor makes twelve claims for the combination of face plate, sleeves, nuts, jaws, and their respective feed motions. —No. 372490, dated 1st November, 1887.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. HIGH PRESSURE TURBINES.

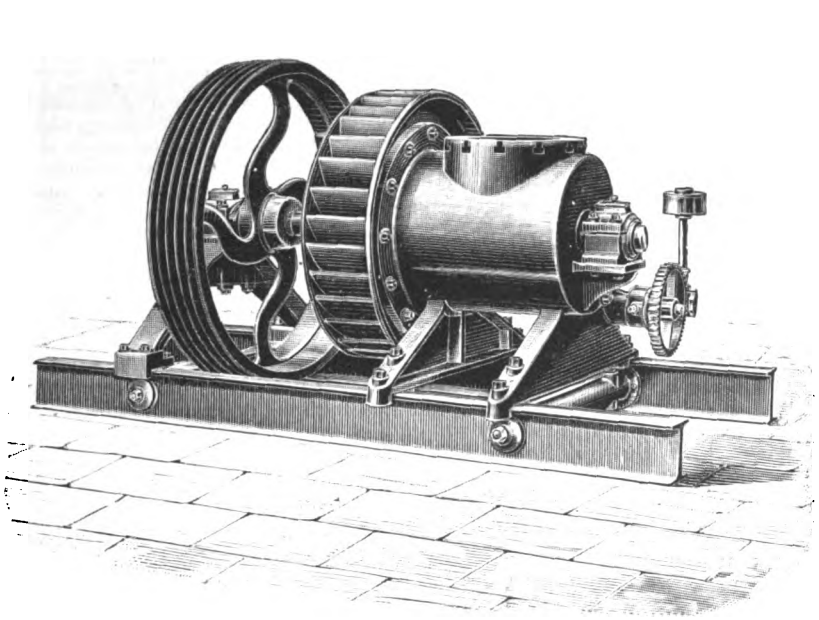

Fig. 1.

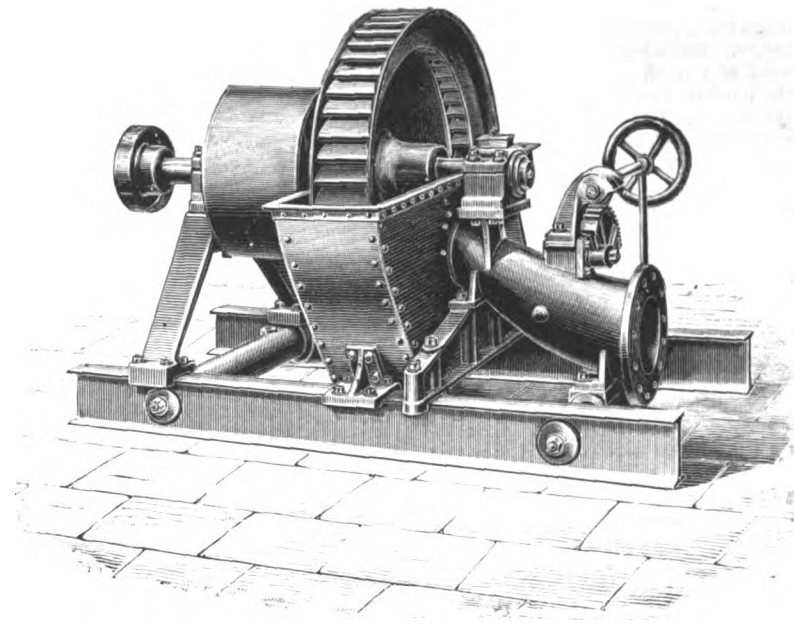

Fig. 2.

HIGH PRESSURE TURBINES.

For a high fall, the Girard turbine has the advantage of a comparatively low speed, due to the fact that the diameter of the wheel can be made as large as desired. The water issues from the guide blades with the full velocity due to the fall, but without pressure, and thus partial admission is possible. This type also admits of perfect regulation without materially reducing the efficiency of the machine. Lastly, its position above the tail water is an advantage, because it facilitates examination and repairs when necessary. The two horizontal shaft turbines shown in our illustrations are of the Girard type, with partial admission, and have been constructed by Mr. Charles L. Hett, Turbine Foundry, Brigg. Fig. 1 is a turbine recently forwarded to Mexico for driving a cotton mill. It is designed to work under a medium fall of 48ft., the water being supplied by a 15in. pipe, and admitted into the horizontal cylinder shown on the right of the turbine wheel. In this cylinder, and within the wheel, are the distributing ports, which are covered by a segmental gun metal valve, with cogs cast on its back. A pinion, driven by the worm and wheel shown on the right, gears into these cogs and regulates the flow of water through the wheel. The regulating gear is controlled by a governor. This governor is placed on the floor above the turbine, and only the lower part of the regulating rod, with a coupling ready for connection to the length above, is shown in the engraving. Hand gear is also added for regulating purposes. The diameter of the turbine wheel is 2ft. 8in.; it runs at two hundred revolutions per minute, and develops 40 h.p. The water outlet is directly under the wheel, the turbine being fixed a few inches clear of the tail water level. To protect the turbine, and to keep the cotton ropes, which transmit the power, free from water, the whole is boxed in with a wood casing, not shown in our illustration. The power is taken off, by cotton ropes, from a 4ft. grooved pulley, and transmitted to a 5ft. 4in. pulley on a lay or intermediate shaft. The turbine is fixed on a pair of wrought iron rolled girders, as shown, the ends of which will be built into the masonary walls of the turbine well.

The turbine shown in Fig. 2 is another example of a partial Girard turbine, supplied for working mining machinery in Bolivia, under the exceptionally high head of 440ft. All parts are therefore very strongly made. The distributor, valve, and turbine wheel are of specially tough gun metal; the main shaft is of steel, with extra long gun metal bearings. The pulley is of wrought iron, and is 24in. diam. and 15in. wide, with two sets of arms. This turbine is one of a pair which are to work together, the ends of the shafts being coupled together by the flange coupling shown on the left. Each turbine is supplied by a 14in. pipe, and runs at a speed of 577 revolutions per minute, developing 80 h.p. The diameter of the turbine wheel is the same as that of Fig. 1. Also in this case the turbine is fixed to wrought iron beams built into the wall. The turbine is protected by a wrought iron casing, of which only the lower half is shown in our illustration. The regulating gear is worked by a hand wheel through a worm and segment. As an approximate rule for the speed of Girard turbines, it is customary to reckon that the wheel has about half the circumferential speed of that which a body would acquire when freely falling from a height equal to the head of water. In the present cases, the circumferential speeds of the wheels at the entrance to the buckets are 27·9ft. and 80·2ft. per second, the speeds of a falling body being respectively 55·5ft. and 168ft. In the first case the ratio of circumferential speed is therefore about ·50, and in the second case ·48, thus showing that the above approximate rule is well borne out in actual practice.

UNIVERSITY EXTENSION AND TECHNICAL EDUCATION.

By Henry Dyer, C.E., M.A.

III.

(Concluded from page 105.)

The West of Scotland affords opportunities for the practical study of almost every industrial art, profession, or trade. Glasgow and neighbourhood, with its immense engineering establishments, shipbuilding yards, and manufactories; Lanarkshire and Ayrshire, with their coal, iron, and steel industries; Paisley, with its artistic textile productions, and many other districts with specialties, all afford opportunities for gaining practical experience, such as are not elsewhere to be met within such a small compass; so that if we had an organisation similar to that which I have suggested, we might do much not only to maintain and extend our manufactures, but also afford to the world an example of the training which is best suited in all departments of industrial art. Organisation, however, must be looked upon simply as a means, not as an end: it must be arranged to assist and guide local effort, not to cramp it or supersede it. The greatest possible liberty, consistent with the general object in view, must be left to the local bodies and institutions, and even to individuals, so that originality may be encouraged and diversity of training produced. Science shows that all progress is from the homogeneous towards the heterogeneous, and the greatest fault of all modern educational methods is that they attempt to reverse this, and produce a dull level of uniformity; and this tendency, if not checked, will end in intellectual stagnation.

Agricultural education is not usually included under an ordinary scheme of technical education; but there are no reasons why it should not, as the subjects to be taught and the methods employed are very similar to those required in what are usually considered industrial departments. In the Glasgow and West of Scotland Technical College we have therefore arranged a course of study for agricultural students, and the classes this session are, I believe, the largest in the United Kingdom. If we had local classes in the different districts for training students in the elements of the subjects, and a few bursaries in each parish to bring up some of the best scholars to the day classes of the College for a session or two, and, lastly, if our most distinguished students could obtain a University degree, I believe that in a very short time there would be a marked improvement in agriculture throughout the country.

We have heard a great deal about the necessity for improved commercial education recently, and I believe that there is as much need for it as for that which is usually considered technical. It *is* technical, and should form part of every scheme of technical education, as many of the scientific classes would be of great use to merchants and others. In the Glasgow and West of Scotland Technical College no special courses of instruction have as yet been arranged for commercial men, although many of the classes are taken advantage of by those who either are engaged or intend to engage in commerce. As the College develops and means increase I have no doubt, however, that arrangements will be made for the systematic education of merchants, either in the College itself, or in an institution affiliated to it and the University. Sir Philip Magnus, in his recent paper on "Schools of Commerce" (*Contemporary Review*, December, 1887), has shown how our existing educational machinery may be modified to meet the demands of commercial education, so that I need not enter into this part of the subject, beyond remarking that the place occupied by many of the special schools on the Continent might be filled to a large extent by the recently founded University Colleges, or by such institutions as the Glasgow and West of Scotland Technical College. The Governors of the latter College have no wish to create a large monopoly under their charge, and are anxious to utilise the work done by any institution when that is of a high order. For instance, in Glasgow we have the School of Art and Haldane Academy. That institution has governors of its own, but arrangements have been made for the recognition of its classes in those parts of the College curriculum where art subjects are necessary, so that, while retaining its independence, it is for all practical purposes a part of the College.

Hitherto the subjects included under any of the university extension schemes have been chiefly of a literary or purely scientific nature, and I trust that those will be continued and extended. An exclusively technical system of education would soon lead to disastrous results. Men would become keen machines for cutting down prices to the last farthing, and what Walter Besant calls the "law of elevenpence ha'penny" would become universal. Pure science, literature, and social politics must always form an essential part of every man's education, so that he may raise himself above his mere selfish interests, and be able to look around on his wider interests as a citizen and a member of the State. Professor Huxley, in his recent address at Manchester, touched on this aspect of the question with his usual sound common sense. After pointing out what was required from a technical point of view, he said: "We have to consider what other matters there are for us to attend to, what other arrangements have to be kept carefully in sight in order that pursuing these ends we do not forget that which is the end of civil existence, that is a stable social state—without which all other measures are merely futile modes of going faster to ruin;" and after entering into details of several parts of the subject, he added: "There comes yet one other question which, I think, is of profound importance, perhaps of more importance than all the rest, and on which I earnestly beg to be permitted to say some few words, and that is not in the strict sense of the word an educational question. It is the need, while doing all these things, of keeping an eye—an anxious eye—upon those measures which are necessary for the preservation of the stable condition of the population, which is the

Digitized by Google

object of all education. You will all recollect that some time ago there was a great scandal, and a very great outcry, about certain cutlasses and bayonets which had been supplied to our troops and sailors. These warlike implements were polished as bright as rubbing could make them; they were very well sharpened; they looked lovely. But when they were applied to the test of the work of war, they broke and they bent, and rather hurt the hand of him that used them than did any harm to the enemy. Let me apply that analogy to the business of education as a sharpening and polishing process. You may develop the intellectual side of people so far as you like, and you may confer upon them all the skill that teaching and instruction can give; but if there is not underneath all that outside form and superficial polish the firm fibre of healthy manhood and earnest desire, your labour is absolutely in vain."

If people would only free themselves from the fetters of mere words, and look at actual facts, conditions, and requirements, much more rapid progress would be made. If they looked upon a university, not simply as a building in which certain professors taught, but as a national institution or organisation for the advancement and spread of useful knowledge of all kinds, in which, while high positions were secured for men of great ability, willing workers of all kinds would be cordially welcomed, for the work to be done is certain to increase largely, and to be very varied both in nature and standard; if they considered "technical education" only as a small part of the work of that organisation, which ought to be developed in due proportion to the other parts, then we might have more logical efforts, and consequently more efficient results. In these articles I have sketched in outline a scheme which in my opinion would meet the demands of the times, and to show that it is no mere fancy, I have explained what is being attempted in Glasgow and the West of Scotland, in order that it may become a reality for that district, and which, with slight modifications, will be applicable to any part of the United Kingdom.

INSTITUTION OF MECHANICAL ENGINEERS.

The forty-first annual general meeting of this Institution was opened on Thursday, the 2nd inst., at the Institution of Civil Engineers; the president, Mr. Edward H. Carbutt, occupying the chair. From the annual report of the Council presented to the meeting, it appears that the membership at the end of 1887 was 1741, as compared with 1674 at the end of the previous year. The receipts during the year amounted to £5,753. 15s. 7d., and the expenditure to £4,787. 10s. 8d., leaving a balance of £966. 4s. 11d. The capital of the Institution amounts to £20,501. 3s. 2d. The report stated that the further series of experiments arranged by the research committee on friction, for determining the friction of a collar bearing, have now being carried out, and the report prepared. A report is in course of preparation in connection with the research upon riveted joints. Some progress has also been made by the research committee appointed to draw up a standard system of marine engine trials, and preliminary work is being done by the committee appointed to inquire into the value of the steam jacket.

The President, in commenting upon the report, congratulated the Institution upon the net gain of sixty-seven members, and upon the value of the papers read during the year. He specially referred to Mr. Wyllies' paper on "Triple Expansion Marine Engines," and stated that a number of steamers were now being altered to triple expansion which had previously been idle. He also called the attention of the meeting to the important recommendations of Lord Morley's committee on guns, which were to the effect that the mechanical work of the Government should be placed in the hands of trained mechanical engineers, instead of leaving it under the entire control of military men. As a member of Lord Morley's committee, he was strongly convinced of the necessity for this change, and he intended to urge it upon the Secretary of State for War.

The first technical business of the meeting was the discussion on Mr. John Richards' paper on "Irrigating Machinery on the Pacific Coast," which was read at the previous meeting of the Institution on the 30th September, 1887, and an illustrated reprint of which will be found on pages 3 and 27 of our current volume. The discussion on this paper was short, and considering the large amount of practical information which the author had placed before the Institution, of comparatively little importance. One of the most interesting facts brought out during the discussion at the previous meeting was that adduced by Professor Unwin, who showed how hydraulic pressure could be used to balance the weight of a heavy vertical spindle, such as is required in centrifugal pumps when placed in a pit (see Fig. 2 on page 4). The author had made use of the one sided thrust on a shrouded wheel for taking part of the weight; but Professor Unwin showed how the weight could be taken by a kind of hydraulic footstep, consisting of a cylindrical cast iron box filled with water, and through which the spindle passes. The box is divided by a circular disc on the spindle into two compartments, and the water in the lower compartment is prevented from revolving by radial plates fixed to the bottom and sides. Similar radial plates are fixed to the disc, and thus when the shaft is in motion the water above the disc is rotated, whilst that below remains stationary. Owing to the action of centrifugal force, unequal pressure is therefore exerted on both faces of the disc, and by suitably choosing the diameter of the disc any desired upward thrust could be produced. To show how powerful this arrangement is, Professor Unwin stated that with a box only 18in. diam. an upward thrust of 1½ tons was obtained. The friction is only about half that of an ordinary footstep. Professor Unwin also drew attention to the fact that the centrifugal pump is simply a reversed turbine, and as turbines show the same efficiency at higher heads as at lower heads, it was reasonable to expect centrifugal pumps to be equally efficient for high and low heads; but the fact was generally overlooked that no single machine could be adapted to great variations of conditions, and therefore centrifugal pumps should be constructed specially for each case. He considered that the low efficiency of the centrifugal pump had arisen chiefly from two causes. The first was that the pump was expected to adapt itself to the motor, instead of the motor being adapted to the pump. The efficiency of the centrifugal pump was very closely connected with the diameter of the pump; and the friction of the pump increased something like as the fifth power of the diameter; whence the waste of work, which was almost entirely friction in the pump, increased very fast if the pump was made of too large a diameter. The second cause of low efficiency was the absence of proper arrangements for utilising the kinetic energy of the water leaving the pump disc. In pumps with shrouded vanes the water between the stationary casing and the pump wheel was put in rotation by the friction of the outside surface of the revolving pump wheel. Consequently the ordinary proportion of pressure or head at the joint round the inlet orifice was only one-fourth what it was at the outer circumference of the wheel; and therefore, although there might be a slight gap at the joint, any leakage at that point he thought was not really a very serious matter.

To these remarks of Professor Unwin, the author of the paper replied by a letter, which was read by the Secretary, and in which he pointed out that in the case of a single inlet pump shrouded wheels caused an axial thrust equal to the area of the inlet multiplied by the discharge pressure. When two or more such wheels were compounded the rotation of the water outside the wheels had to be prevented by baffling vanes or fixed guide blades, in order to destroy centrifugal effect, and so permit the water to return to the centre of the second wheel. The axial thrust of the pump discs was not well understood. A wheel of 24in. diam., without the vanes on the back, would, when working against a head of 40ft., sustain an axial pressure on the back of more than 7000lb. This was opposed by less than one-half as much pressure on the front face, leaving what might be called a destructive force pulling the wheel and spindle towards the front of the inlet face. The pressure resulting from the impact of the entering water on the front of the receiving face, and the gradually increasing pressure on this face from the central inlet to the circumference, were subjects well deserving attention from a scientific point of view; as was also the pressure at different points of the pump casing from the central axis to the circumference, which, so far as Mr. Richards knew, was a matter not yet treated in any literature upon this subject.

Mr. Davey thought that the centrifugal pump (Fig. 5) could not give a high efficiency. Such a pump should have a free vortex; but in this case the water was baffled with the object of compelling it to leave the first pump and go to the second, and then it was baffled again to go from the second to the third. Guide vanes had been put in pumps with the object of utilising the energy in the vortex; but unless properly disposed, they did more harm than good. Guide vanes were useful if they were above the free vortex, and not too many were put in. With regard to the collar bearing, he did not consider it suitable for carrying heavy weights. When bearings of that kind had failed he had used the "onion" bearing, introduced by Messrs. Easton & Anderson, which was entirely submerged in oil, and being free did not bind the spindle in any way. It was not so with an ordinary collar bearing, which had to perform two functions, viz., support the load, and also centre the spindle. In one case he took out a thrust block that had given trouble and substituted an onion bearing of only a third the surface, and he never had the slightest trouble with it afterwards. The principle of balancing the weight of a centrifugal pump wheel and shaft by one sided water pressure was by no means new, having been introduced by Messrs. Easton & Anderson in one of their earliest designs, in which the wheel was hung from the onion bearing attached to the overhead girders; and to the same girders were attached the suspension rods of a circular disc covering the upper surface of the wheel, with just sufficient clearance round the rim to prevent excessive leakage. Thus the pressure was taken off the top of the wheel, and whatever small quantity of water leaked into the disc was allowed to escape to the inlet of the wheel through the openings near the shaft.

Mr. Mair, after pointing out that the diagram criticised by Mr. Davey referred only to a proposed pump, and not to one actually constructed, drew the attention of the meeting to the comparative efficiency of reciprocating and centrifugal pumps as affected by the lift. On a lift of 22ft. the efficiency of a reciprocating pump might be taken at 55 per cent.; but for higher lifts up to 100ft. the efficiency increased very rapidly, whilst for lower lifts than 20ft. it was very low indeed. On the other hand, the efficiency of the centrifugal pump was high at moderate lifts, and decreased rapidly for high lifts. If the curves of efficiency be plotted as affected by the lift we obtain two curves, the crossing point of which indicates that lift for which both kinds of pumps are equally efficient. Speaking from memory, he thought that this lift is about 35ft., but the point is also affected to a certain extent by the consideration that with a reciprocating pump we must have an engine of low piston speed which in itself may be less efficient than the high speed engines usually employed with centrifugal pumps. The speaker, however, did not say what was the size of pumps which he compared, and as it is obvious that the efficiency of a centrifugal pump does not only depend upon the lift, but also upon the quantity of water to be raised per minute, his limit of 35ft. can hardly be considered as universally applicable. He also pointed out that for very low lifts of say about 10ft., centrifugal pumps become again less efficient, and that the best machine for raising water is then a scoop wheel, preferably of the form devised by Sagebien, the celebrated French engineer. The efficiency of these wheels may reach 80 or 82 per cent.

Mr. Richards, the son of the author of the paper, drew the attention of the meeting to the way of balancing the weight of the pump by water pressure, and asked whether similar arrangements had been previously used. To this question Mr. Schoenheyder replied by saying that Mr. David Thompson, twenty-five years ago, had already employed this principle, not only to balance, but even to overbalance the weights, so that there was an upward thrust on the collar bearing.

Mr. Wm. Geipel then read a paper on "Prospects of Electricity as applied to Engineering," which we reproduce on page 146, and the discussion on it was opened by Mr. Fearfield, of Stapleford, who reminded the members that before long they would have to take up the subject of electrical engineering as one of the regular branches of their profession. He himself had already devoted considerable attention to electric lighting and transmission of energy, and had found that electricity possessed all the advantages claimed for it in Mr. Geipel's paper, but that the author had neglected to point out one important matter, which in certain cases might seriously counterbalance the advantages, viz., the cost of repairs to electrical machinery, and especially to the armature and commutator. He had several dynamos running in his own works, and found that the commutators wore and required renewing, the cost of repair being £4 to £8, and in one instance even £10 per armature, which originally only cost £18. It was important not to oil the commutator too much, so as to avoid its flashing round; whilst on the other hand, if allowed to run dry, the copper dust would find its way into the armature and destroy the installation. In his experience the cost of electric lighting depended entirely on the size of the installation. In Nottingham the Corporation supplied gas at 2s. 4d. per thousand cubic feet up to a distance of nearly eight miles from the gas works, and the electric light might be either slightly cheaper or very much dearer than gas light, according to the number of lamps installed in each works. In some large installations it was cheaper, and to obtain an equal amount of light from gas at the same annual expenditure, the gas would have to be sold at 2s. 1d. per thousand; whereas in the smallest installations the expenses increased rapidly, making the equivalent in gas nearly 7s. per thousand. He found incandescent lighting specially suitable for his lace factories, where, besides conducing to the better health of the work girls, there was the absence of dirt, a better light, and a saving of spoilt stock, on account of the absence of dust on the lace. To show how easily and quickly electric lighting apparatus can be fixed, the speaker mentioned that when on the occasion of a party given in a house adjoining their factories some electric lights were required, two men ran the leads and fixed twenty-four glow lamps in the garden in front of the house within two hours. The lights were worked for two nights, and were taken down afterwards within the space of an hour and a half. Mr. Fearfield also referred to the question of safety, and criticised adversely the statement in the paper that 600 volts is the

Digitized by Google

upper safe limit of pressure for electric tram cars. He thought the day had already gone by when electricians considered 2000 volts an excessive pressure, and that currents of 10,000 volts will in future be looked upon as perfectly safe. It was, in fact, very much the same as with steam. In the early days of steam engineering a pressure of 10lb. per square inch above the atmosphere was considered high, but now they work with 160lb. and 200lb. in perfect safety.

On Friday, before resuming the discussion, the Secretary read some letters received on the subject. Among these was one from Mr. Albion Snell, in which he criticised the author's statement that 70 per cent. efficiency had been obtained in the Kriegstetten-Solothurn transmission plant. In his opinion the actual efficiency should only be taken at 50 per cent. Another letter from Mr. Thomas Urquhart described the electric welding process as carried on at Dr. Bernardos' works in St. Petersburg. As we have already described this in our columns we need not reproduce this letter, but would simply state that some of the specimens shown to the meeting could by no means be called samples of good welding. The two pieces of metal were simply fused together on the surface. An interesting application of cutting metals by Dr. Bernardos' process was, however, mentioned. This referred to a proposal to cut up an iron bridge which had fallen into a river, so that the separate pieces might be lifted. It appears that by passing the carbon pencil under water, along any metal surface, the latter can be cut by fusion, and thus the whole bridge could be cut up into manageable pieces.

The discussion was opened by Mr. Shoolbred, who indorsed the author's statement that the electric power business will in the near future become of greater importance than the electric light business, and he contended that for this reason local authorities, if they establish electric lighting stations, have no right to adopt any system which precludes the use of electricity for motive power purposes. In making comparisons between the cost of electric and gas lighting, the circumstance was generally overlooked that hitherto the former was carried out on a comparatively small scale, whereas the number of lights supplied from a gas works was hundreds and thousands of times larger than those in an electric installation. If they found that even under such disadvantages the electric light supplied from isolated small installations became comparable in price with gas lighting, it is only reasonable to suppose that if all these separate installations were concentrated in one central establishment the cost of lighting would be reduced below that of gas. The author had mentioned Messrs. Jagers' sugar manufactory, and Mr. Shoolbred wished to draw attention to the large installation which is now in use at Messrs. Tait's sugar works in the east of London. This had grown from a small beginning eight years ago, when only a few arc lamps were used, to its present dimension. The incandescent lamp is employed throughout the works, and no gas at all is used, although the works are close to the Beckton gas works. Messrs. Tait employ about 1000 men in their London works, and so satisfied were they with the economy and convenience of the electric light that they erected a similar installation in their Liverpool works, where an equal number of hands is employed.

Mr. Magnus Volk asked the mechanical engineers not to look upon electricity as though it were a rival, but rather to regard it as a useful adjunct to the forces which form the basis of engineering. Electricity simply serves to transmit power from one place to another, but can in nowise generate power. Electrically propelled trains could climb steeper gradients than those drawn by a locomotive, and the cars on a downward slope would return power to the system to assist cars on the upward slope. On his own line at Brighton, which is nearly a mile long and contains some heavy gradients, the motors were put under the floor of the car, and the power was transmitted by leather link belts. The repairs were trifling. The first motor which began running, in April, 1884, had only one set of new bushes after three years, and the life of a belt is about four years. He considered that 10 per cent. would cover depreciation, renewals, and repairs. On this line gas engines are used for driving the generators, and the actual working expenses during the past four years, including gas, oil, and waste, amounted to £430. 13s. 7d. The repairs to the gas engines (refacing of slides, packing, &c.) amounted to £16. 7s. 5d., and repairs to the dynamos and motors amounted to £64. 5s. 6d. The total mileage of the cars for the last four years was 94,000 miles. The working cost per car mile is 2·1d., including 1·02d. for gas, oil, and waste, ·04d. repairs to engines, ·16d. repairs to dynamos and motors, and ·7d. wages.

Mr. Holroyd Smith objected to the author's statement that in America the practice and in England the science of electrical engineering are further ahead. He thought that both in science and practice the Americans led the way. An American would generally accept the first solution of a problem and carry it into effect without loss of time, whereas an Englishman would always seek for some better solution, and end by not doing the work at all. Another reason why electrical engineering is progressing much faster in America was the tolerance of the people towards new enterprises, which in England would meet with continual opposition on the score of unsightliness or inconvenience. He thought that the colossus Brush machine used in the Cowles aluminium process was a striking example of the perfection of American engineering, and when last in New York he was shown a closed box, which the owner assured him would without application of power or batteries transform high tension continuous currents into low tension continuous currents. He could not say how this was done, but it had certainly not been done in England. He also thought that the Thomson welding process was far better than that devised by Dr. Bernardos, which would prove an absolute failure. Referring to his electric tramway at Blackpool, Mr. H. Smith wished to correct the statement of the author that his cars were driven by worm gearing. As a matter of fact he had only employed worm gearing on a car which was sent to France, but on the Blackpool line the first motion was by internal spur gearing, and the second motion by chain gearing. To tighten the chain the internally geared wheel could be shifted round on a centre coinciding with that of the armature spindle, and the jerk at starting was taken off by a spring connection between the chain wheel and its spokes on the car axle.

Dr. Hopkinson described his system of overhead conductors, to which we made reference in our article on the Lineff tramway. He also pointed out that the property of self regulation on a shunt wound motor was not peculiar to the Victoria type of machine, but was shared by many others. The reason why the machine was self regulating was not only on account of the low resistance in the armature, but also because the brushes had to be set with a backward lead, and as the current increased the strength of the field was slightly decreased, which was the very condition required for obtaining constant speed under varying loads.

Sir James Douglas thought that electrical engineering had not progressed so slowly in this country as was made out by the previous speakers. In his own experience the weak point of installation was rather with the motor than with the dynamo, and this tended to delay progress. His work had been in the development of electric light for lighthouses, and it appeared that the light had a power actually beyond what was required, and the only thing that mariners complained about was that at times they had too much light.

Mr. Crompton strongly opposed the views put forward by Mr. Holroyd Smith with reference to the comparative merits of English and American practice. All the great improvements in dynamo machines had originated in England. The largest dynamo in the world had been made by himself, and unlike the Brush colossus, which was designed to develop 400 h.p., but only developed 200 h.p., his own machine had actually developed the 500 h.p. for which it was designed. The first time he had used an electric furnace, he could hardly believe that such intense metallurgical action was going on in the small box he had before him; but when the operation was finished, they found that direct from the charge of corundum they had obtained a large ingot of aluminium bronze, containing about 50 per cent. of aluminium. He thought mechanical engineers were hardly aware of the enormous future which was before the new industry of electrical engineering.

Mr. Cochrane directed the attention of the meeting to the beautiful and ingenious turbo generator devised by the Hon. C. Parsons, and of which a description appeared in our issue of 13th January.

Mr. Thomas Gower referred to the electrical service on the North Metropolitan Tramway, where during six months 30,000 car miles had been run, and over 300,000 passengers carried. He was not prepared to give the cost per mile, but he thought that as accumulators became improved the cost would not stand in the way of electric traction. From any depôt in which they could put a dynamo, and a steam engine or a gas engine, they could run storage cars, whereas with any system of conductor they would first have to specially prepare the road and conquer the prejudices of the local and central authorities.

Mr. Kapp confirmed the author in his statement regarding the efficiency obtained in the transmission plant at Solothurn, notwithstanding Mr. Snell's letter. The discrepancy was due to a misconception on the part of Mr. Snell. When measuring the commercial efficiency of a system of transmission it was unfair to take as a basis the power which the turbine could give. They must take the power which the turbine actually did give, and compare it with that actually obtained at the other end of the line. The experiments were carried out by a committee of scientific men, and from an advanced proof of the report which had been sent to him by a member of the committee, he found that the commercial efficiency of the plant was not 70 per cent., as stated by the author, but actually 75 per cent. Referring to the very mysterious apparatus which Mr. Holroyd Smith had seen in America, Mr. Kapp thought it was probably a continuous current transformer of the type originally invented by M. Gramme, and lately taken up on a large scale by an English firm of electricians. He had himself tested this apparatus and found the efficiency to average 90 per cent. Referring to Dr. Hopkinson's ingenious system of overhead conductors for tramways by which the difficulty of crossings was overcome, Mr. Kapp pointed out that quite recently an underground system had been developed which has the same advantages. This was the invention of Mr. Lineff, who had laid down an experimental line at the Chiswick depôt of the West Metropolitan tramways. As we described this in our issue of last week, we need not report Mr. Kapp's explanation of the system.

Mr. Henry Davey objected to the use of electricity for underground pumping, partly on account of the difficulty of reducing the speed from the fast running motor to the slow running pumps, and partly because such pumps must often work when completely submerged. For this reason he preferred the application of hydraulic power. He thought that electric transmission of energy would come into extensive use only in such cases where the distance was great.

Mr. Mordey said that although at the present time electricians generally are aware that a shunt wound dynamo makes a self regulating motor, when his curve was published very conflicting views were held by electricians on this subject, and only a week previously Dr. Frölich had published an investigation on self regulating motors, in which he completely missed the most important point. For a long time a theory advocated by Professors Ayrton and Perry was current, according to which in a motor the armature should be very large, and the field magnets small and weak. This theory he considered now exploded, the best dynamos making also the best motors. He thought that English electricians always made inventions, but seldom utilised them. This was left to American electricians, who thus reaped the benefit of our own scientific progress.

After a few remarks from Mr. Shippey on the use of fire damp as a source of motive power, the discussion terminated.

Mr. Geipel, in his reply, thought that Mr. Fearfield must have been particularly unfortunate in his dynamos, in which the armatures were continually scrubbing, the commutators wearing, and the brushes sparking. He had experienced none of these difficulties in the many installations which had come under his own care from time to time; in which the attendants were not even skilled mechanics, but only labourers. He did not think the size of an installation above a certain minimum had so much to do with the working expenses as the number of hours the light was required annually. If the time of lighting exceeds one thousand hours, the cost per lamp hour is fairly low; but when the lights are only required for a few hundred hours, the cost became very great. The advantage an electric motor has over the steam engine is that it can exert a very much greater static effort when the load is suddenly increased. With a steam engine, the turning movement on the crank shaft is limited by the dimensions of the cylinder and the steam pressure; but with an electromotor there is practically no limitation, provided there is a sufficient supply of current on the mains.

The President, in proposing a vote of thanks to the author, congratulated the meeting upon having listened to a paper which was a fairly complete *résumé* of the present position of electrical engineering, and he thought that the advances made in electrical science would put abundant work into the hands of mechanical engineers, and thus benefit their profession.

NOTES ON FOUNDRY WORK.

By the Author of "Pattern Making."

(Continued from page 85.)

XII.

Flasks.—Foundry flasks or moulding boxes are stout frames of cast iron for enclosing the sand in which the moulds are made. They are therefore of every conceivable shape and size, but they may be divided into two main classes, viz., boxes for general use and boxes for special use. The first ones are mostly made of rectangular shape, both square and oblong, and of different dimensions. The depth is approximately proportional to the area, and is rather small in comparison to some of the work moulded in the boxes. Thus, when deep castings have to be made, the necessary depth is usually obtained by the superposition of several shallow "middle parts," two, three, or four of them being usually kept in stock for each top and bottom part. The "top" or "cope" A (Fig. 67), is always made with vertical "bars" or "stays" A^1, the "bottom" or "drag" B (Fig. 67), with flat bars A^1, the "middle" C (Fig. 67), without bars, but having a fillet B running round the internal bottom edge, and sometimes also round the top edge. The relative position of the flasks when the mould is complete is as follows; B is

NOTES ON FOUNDRY WORK.

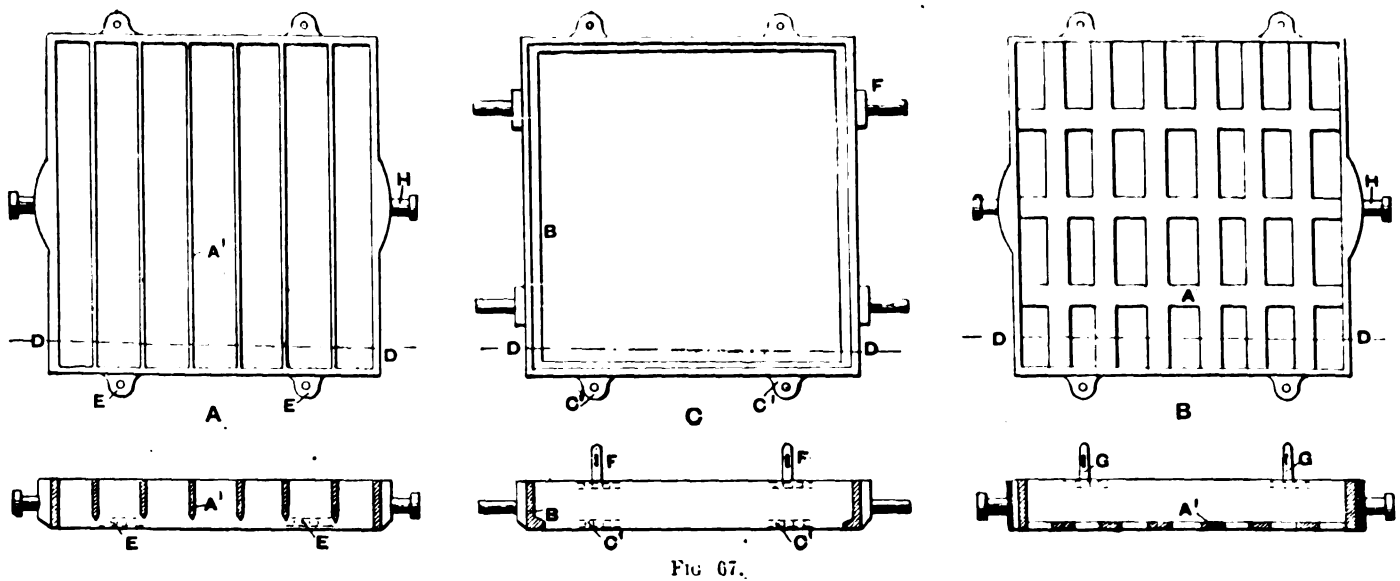

Fig 67.

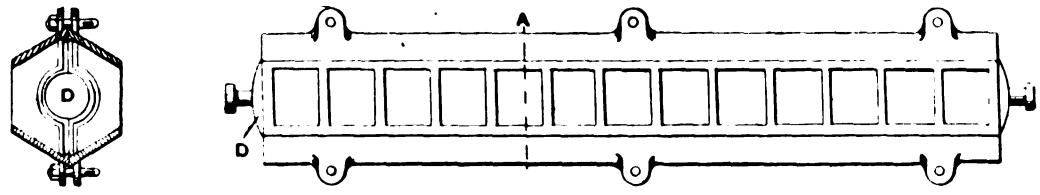

Fig 68

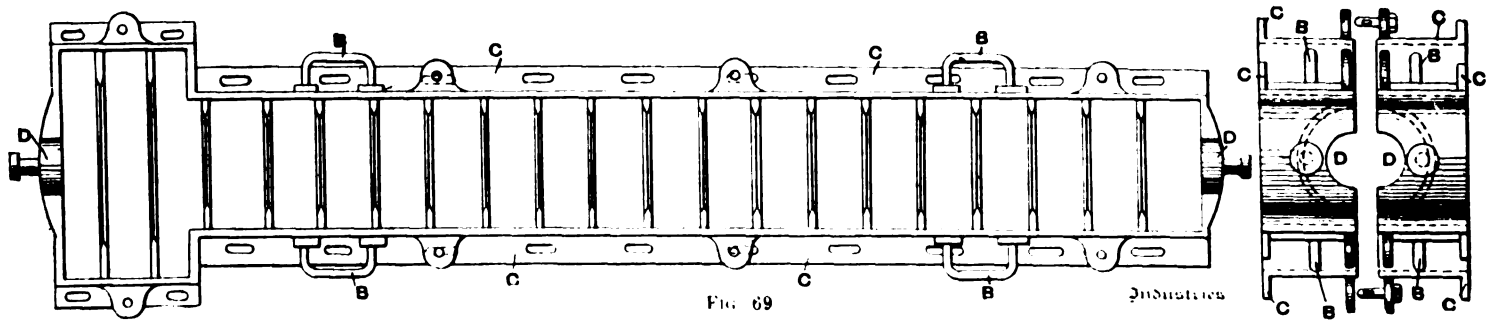

Fig 69

resting with the flat bars A¹ on a level bed of sand; C rests on B, the holes C¹ over the pins C¹ fastened in the lugs of B. Flask A is laid upon C, the holes E fitting over the pins F of flask C. If the middle box C admits of bars being used they are put in temporarily. Often, however, iron rods are driven in, and give support to the lifters, binding the sand together and preventing a "drop out." Fig. 67 therefore illustrates the usual type of "three parted" flask employed for general work. Special boxes, on the other hand, are made shallow or deep as required, the bars are cut to the outline required, the joints are sometimes bevelled and if needs be curved, while the sides are made to follow the outline of the pattern sides, in order to economise sand and labour in ramming. Such special flasks are often broken up after they have served their purpose, so as to keep all available space and capital for standard boxes. The regular flasks will range from 6in. square upwards to say 12ft. square; or if oblong, from 1ft. or 2ft. long to 20ft. in length, the dimensions of course depending on the general character of the work which is done in a particular foundry. The considerations to be regarded in making moulding boxes are not so much strength, which is almost always in excess, as stiffness. A box which springs will always give much trouble through the dropping out of sand and the crushing of moulds. It is poor economy to stint the metal in moulding boxes, since iron is always worth its first cost. But, on the other hand, flasks made too heavy involve more labour in carrying when of small size, more strain on the cranes if of large dimensions; therefore the boxes ought not to be made heavier than absolutely necessary. If the boxes be stacked out of doors, something ought to be allowed for annual loss due to rust. We illustrate in the succeeding figures some flasks of different shapes, and as all the parts are drawn proportionately, a good idea may be obtained of the relative dimensions.

The cope A and drag B (Fig. 67) have straight bars, but standard boxes for columns and pipes are necessarily fitted differently, as they have no middle, but only drag and cope, which are both alike, as shown in section in Fig. 68 and end view in Fig. 69. To save sand space the sides of such flasks are often sloped, as shown in Fig. 68, or a pocket is provided in cases where a large flange or a base has to be cast at one end of a pipe or column, as shown at the left hand of Fig. 69. The holes D at the ends of these boxes are made to receive the ends of core bars. Circular flasks like Fig. 70 are made with cope, drag, and middle like Fig. 67. Small hand flasks like Fig. 71 are made from 6in. to 10in. or 12in. square, and others, like Fig. 72, from about 12in. to 20in. square. There are some essential points of detail about these boxes which should be borne in mind. As regards the patterns, there ought to be plenty of taper everywhere. This is necessary to facilitate moulding, and rough flasks will not pay for the time spent in mending up. There should be given not less than $\frac{3}{16}$in. of taper per foot of depth to the sides, and $\frac{1}{4}$in. to the bars. The bars are to be chamfered to about $\frac{1}{8}$in. in thickness at the edges, as shown in A A¹ (Fig. 67), and in Fig. 69. This chamfering allows the sand to be rammed close around the pattern, without leaving soft unrammed spaces underneath the bars. All the boxes' sides and bar faces ought to be left rough, in order to take the clay water which is poured over, and to cause the sand to adhere thereto. It is a not unusual practice to roughen the vertical faces of the flasks by thrusting a stout vent wire between the flask pattern faces while yet in the mould, and the abutting sand, so that after the pattern is drawn, and the metal poured, the faces present a ridged and rough surface. With pipe and column boxes it is often the practice to diminish the total number required for stock by making "pockets" A (Fig. 73), to bolt on the ends of the actual boxes B. Thus a 12ft. box could be extended to 16ft. by bolting a 4ft. pocket on the end. A pocket can also be put on the side of a flask to receive the branch piece of a pattern, or any similar lateral extension; but an opening must be cut in the side of the box at the place where the pocket abuts. When the latter is not required for present use the opening is closed with a piece of plate bolted against it. The cutting out of the side of a flask in this fashion tends to impair its rigidity, and should only be adopted to a limited extent. Pockets are fastened in any manner most convenient. If provision is made beforehand for them, flanges are cast on the flask ends C (Fig. 73); but if no flanges are provided a pocket can always be put on by extending its sides to embrace the sides of the flask. Where a box like Fig. 73 is required of its normal length only, the piece A is removed, and an end plate is bolted in its place, as shown in Fig. 74.

For common and jobbing work the joints of the flasks are left rough, just as they come from the sand; but in order to obtain the best results, as in repetition and certain other classes of work, their joints are, or should be, planed, to make a close fit with each other. In some works they plane all or nearly all the box joints, while in others the practice is exceptional. For common work it is not necessary, but in cases where patterns are jointed—more especially if they are long and slight, and likely to become curved or twisted in their joint faces—there is a decided advantage in having planed joints for the flasks. Then the sand can be strickled off level, thereby giving a perfectly true face to lay the pattern joint on for ramming up. In the case of deep moulds poured vertically there is also less risk of the boxes becoming strained and started under pressure, and of the metal finding its way out of the joint. And beyond these instances of acknowledged advantage, I think that in a shop doing good work it is always wise economy to plane the joints of all the standard flasks—that is, those which are in regular use.

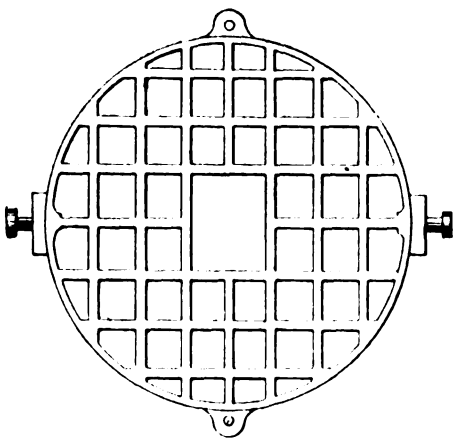
It is often convenient to utilise a middle part as a cope for some special purpose by making loose bars, and bolting or wedging them in, as shown in Figs. 75 and 76 respectively. And by means of such loose bars a column box, both cope and drag parts, can be used for columns of different diameters, and having caps and bases of different shapes and sizes, by substituting one set of bars for another. The practice of using loose bars is in such cases capable of effecting a considerable saving in the weight of boxes kept in stock in a jobbing shop. Another makeshift plan is to use wooden bars for temporarily arranging flasks to stand a few rammings. This is a handy and convenient method, because the bars can be cut to match the outlines of the pattern, and if spruce deal or slab is used the cost is trifling. In some out of the way shops flasks made entirely of wood are employed; but considering their fragile character, and the certainty of becoming cracked and burnt, it is difficult to see wherein their economy lies. They are used more in America than with us.

Digitized by Google

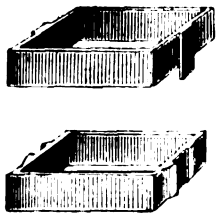
A middle part can be utilised as a drag by using a latticed plate A (Fig. 77) as a substitute for bars, and bolting it to the middle part B. Many of the larger and heavier rectangular flasks are economically made by forming sides, ends, and cross bars in separate pieces, and bolting them together, the advantage being that they are cheaper to make in the first instance, and by the substitution of new sides, or ends, or cross bars, the size of the flask and the shape of the bars can be modified to suit patterns of different dimensions and outline. This is only an extension of the method of using loose bars.

For uniting flasks, lugs and pins are provided, as shown in the illustrations. These pins may be differently fitted. First, they may be roughly forged, and drop loosely in their holes, or they may be turned pins, closely fitting; and in either case they may be short or long. Where good work is expected to be done, they should always be long turned pins (Fig. 78), fitting closely, yet freely, into drilled holes. The evil of using badly fitting pins is that the moulder cannot trust to them for the adjusting of his box parts truly to one another, and so prevent lapping joints, since the flasks may have as much as $\frac{1}{8}$in. or $\frac{1}{4}$in. of play on their pins, causing the risk of lap to that amount. He has therefore to rely entirely on the correspondence of the trowel marks which he makes on the whitened sides of the flasks. Short but well fitting pins are suitable enough for flat work; but in cases where there are deep vertical sand joints, or cores standing up, and entering into deep prints, these joints and prints may, and often do, become crushed during the lowering of the upper flasks before the pins can enter their holes. Long and truly turned pins ought therefore to be provided which enter their holes some time before the box joints come into contact, so that for a distance of from 2in. to 4in. before any sand faces come into contact the flasks are being closed by the guidance of the pins alone. These should therefore measure from about 7in. to 10in. in length, according to requirements, and be turned parallel throughout, never tapered—a rounding off of the points only being permissible. They are attached to their lugs in the manner shown in Fig. 78.

Flasks are cottared, bolted, clamped, or weighted. Cottaring is the simplest plan, and is as safe as bolting, as there is no bother with burred threads; but the cottars should be deep, or they will probably be broken off. Bolts are often used for work cast vertically in the pit, cottars being liable to become knocked out during the ramming of the sand around the flask. Weights are used for bedded in work, and clamps generally instead of cottars and bolts. But the wedging of clamps is not so secure as the fastening of cottars and bolts; yet it often supplies a ready mode of union, and is therefore often resorted to.



Various attachments are provided for moving the boxes. All flasks have to be turned over, either for moulding or for cleaning up. The smallest of all, say those under 12in. square, are often made without handles, like Fig. 71, the sides of the boxes being grasped by the hands. Flat lips or handles may be cast on, standing out from opposite sides. Boxes measuring from 12in. to 18in. or 20in. square are often provided with handles made of wrought iron rods, like Fig. 72. But most flasks above these sizes up to the largest have handles of cast iron or of wrought iron cast in, shown at F (Fig. 67), the latter being preferable, because less liable to break off. Large flasks are provided with swivels made of wrought iron, and cast in, shown at H (Fig. 67) and D (Figs. 68, 69), the metal being thickened around them to give sufficient hold. That portion of the swivel around which the metal is poured is made square, and jagged (see Fig. 79), square to prevent the possibility of its turning round, and jagged to better hold, and prevent loosening under stress. A pocket print is put on the pattern for each swivel (shown dotted in Fig. 79, section). The sand is dug away beyond the print thickness, in order to allow the neck of the swivel to bed down into the print. When in place, the sand is stopped over it, leaving the square jagged portion projecting into the space which the metal will ultimately fill.



But swivels only serve the purpose of turning over in the crane slings, with the boxes in even balance, but form no point of attachment for applying the force necessary for turning a set of heavy flasks over, or for lifting or lowering them into the foundry pit. The loop handles B (Fig. 69) are used for these purposes, sling chains and hooks being attached to them. The straight handles on boxes like Figs. 67 and 77 are also employed for turning the flasks over.

When casting deep work in the foundry pit, back plates are bolted on the flasks to prevent the pressure of the liquid metal from forcing out the sand. Flanges C (Fig. 69) are therefore cast on many boxes, to afford a surface of attachment for the clamps or the screw bolts used for that purpose, the latter passing through the slot holes in the flanges C.

The method of making flasks was partly described in the article on moulding in open sand, in *Industries*,

Fig. 85.

Vol. III., page 56. Some of the minor details will therefore only be noted now. Swivels are cast in the pocket prints; so are also plain handles like those in Fig. 67. Handles like B, in Fig 69, require that two prints be put on at the centres where they enter the box sides, and the sand without is cut away to clear the looped portion. Lugs may be put in variously. When they are wanted only in the bottom or in the top, they are best made in a core box like A in Fig. 80, which shows the lug. The lug centres being then marked on the edge of the pattern, the sand in the vicinity is dug away, and the cores bedded in, a centre line on the core being brought to correspond with the centre line on the box. Fig. 81 shows such a lug core A in place, and the sand made good over it to the edge of the mould. Another method is to dig out the sand, lay in, and mould a lug pattern, with or without a round print for the pin hole, shown in Fig. 82, then to withdraw it, and cover over the space left with a piece of slate B, or with a piece of loam cake, and finally ram the sand above it. If a number of standard flasks are required it pays to put the lugs in the pattern with prints above them, and make plain cores simply to fill the prints. Fig. 83 shows the relations of the lug, print, and pattern side. In middle parts two lugs will often come over one another on opposite edges; then, the mould being in open sand, the top lug cannot be left as when a cope is used, but must be put in a core box. In that case, as in Fig. 83, the rectangular core A fitting in the print would have a lug formed in its top face. Handles cast in circular bosses, as in Fig. 72, would be carried in a core, whose print is shown in A (Fig. 84), and its core box in section, in Fig. 85, the handle being rammed up in the core, the jagged portion, which is cast in, passing through holes cut in the pattern bosses and bottom board.

Weak flasks get sometimes broken at the corners through rough usuage, and straps of wrought iron are conveniently used for their repair. If broken in several places, or thinned and greatly weakened by rust, it is cheaper to break and melt them up than to continue patching. If bars require to be cut out for clearing parts of patterns, they are nicked with a cold set, and struck with a hammer, a sledge being held against the side opposite to which the blow is struck, to prevent jar and extension of the fracture, or numerous holes are drilled through the bars to facilitate their separation. When copes are shallow and weak, stiffeners or binders, consisting of rigid bars of cast or wrought iron, are bolted on the top to increase their rigidity. When the area of a mould is such that the largest cope in stock is not sufficient to cover it, two or even three copes are placed end to end, leaving a space of $\frac{1}{4}$in. or $\frac{3}{8}$in. only between them, which is filled in with loam or sand.

These remarks embrace the essential features of flask making generally, though, as was remarked at the commencement, special work demands flasks specially adapted thereto.

(To be continued.)

PETROLEUM.—The fact that small springs of petroleum, together with certain gases, have been met with in the course of boring the Suram tunnel, have given rise at Baku to the opinion that large supplies of petroleum probably exist in the interior of the Caucasus. A large petroleum field has been opened on the shores of the Black Sea, in the Government of Kutaisk, on the estate of Prince Gourieli. It has been taken up by some large capitalists. The great petroleum fountain at Baku has at last ceased to spout, although the oil in the well is still agitated.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 7TH FEBRUARY, 1888.

THE IRON MARKET.—Though the business in iron is not animated, the general situation is to be regarded as satisfactory. The fear of competition in the Paris market between the Centre and the North has subsided, a complete understanding having been arrived at between the contending parties. The market, which for a moment became disorganised, has consequently regained its former strength. Business is fairly active, and there is no question of lower prices. There is a strong feeling among the iron masters against rushing up prices in the way the Germans have done, and it has to be borne in mind that one effect of the hard times through which we have passed has been to cheapen production, so that a small advance will be sufficient to give a fair margin for profit. The wire syndicate has announced a rise of from 2fr. to 3fr. a ton. The difficulty experienced in renewing the Treaty of Commerce with Italy has had a disturbing influence on the iron market.

THE METAL MARKET.—Copper is so completely in the hands of the syndicate that its fluctuations in price are in no degree dependent upon commercial conditions, and it is impossible to predict its movements. Little or no genuine business takes place, consumers holding off in the hope of a relapse. The syndicate is now endeavouring to bring about a combination of the principal mine owners to keep up the price of copper. If they succeed in their attempt, the present high rates will be maintained till a greatly reduced consumption has modified the conditions of trade. The over-inflated tin market shows signs of collapsing. Prices fluctuated between £98 and £105 in the first nine months of last year, and then ran up to £165 before the end of December. But the stocks were considerably greater at the end of 1887 than at the end of the preceding year, and they have increased since. Present prices are thus out of accord with the condition of trade, and, like those of copper, are wholly dependent upon the "rising" of speculators who have "cornered" the market. In this case, however, the end appears to be near. Spelter, which at present moves in a sure market, is still in strong demand at full prices.

FOREIGN COAL IN FRANCE.—The consumption of coal in France in 1887 was considerably greater than in the previous year. Not only has the larger home production been absorbed, but increased imports have been called for. The Customs returns show that the total purchases of foreign coal delivered for consumption in France amounted to 8,473,473 tons in 1887, against 8,366,239 tons in 1886, and 8,811,489 tons in 1885. Of last year's quantity, 41·58 per cent. was derived from England, 48·15 per cent. from Belgium, and 10·24 per cent. from Germany. There were also imported 1,065,771 tons of coke, against 1,058,756 tons in 1886, and 1,131,980 tons in 1885. Of last year's imports, Belgium furnished 72·72 per cent., and Germany 25·30 per cent. The home production of coke was in 1887 considerably above that of the previous year.

HOURS OF LABOUR FOR WOMEN AND CHILDREN.—M. Richard Waddington has presented to the Chamber of Deputies his report on the hours of labour of women and children. He recommends the following modifications of, or additions to, existing laws, which, if adopted, will tend to increase the cost of production in all industries: (1) Extension of the system of Government inspection to all public schools and to shops; (2) the abolition of the practice of half time, and the raising of the limit of age from twelve to thirteen years; (3) the institution of a certificate of fitness for all children under sixteen; (4) the reduction of the working day to ten hours for all under eighteen years of age, and to eleven hours for women; (5) the prohibition of night work for women and all under eighteen years of age; (6) the prohibition of Sunday labour for the same classes of persons; (7) the temporary prohibition of all work for women after child birth; (8) the raising of the limit of age to fourteen for boys employed in mines.

BERLIN, 6TH FEBRUARY, 1888.

THE IRON MARKET.—Some little flutter has been caused in the German iron market by the new French law, according to which the existing traffic in *acquits à caution* has been abolished. German crude iron may still be imported into France duty free under special permits, but the latter are henceforth not negotiable. The German iron market continues firm. In Upper Silesia there are twenty-eight blast furnaces at work, the production of which is estimated at 35,000 tons per month. Of this quantity 26,000 tons is forge pig, 2000 tons foundry pig, and the rest Thomas, Bessemer, and other special brands. The demand for crude iron continues brisk, and blast furnace owners have no chance of accumulating stocks. The present ruling prices at the works are 50s. for forge pig, and from 56s. to 58s. for foundry pig. Rolling mills in Upper Silesia are well supplied with orders, which will last them over the present quarter. The demand for wire and French nails continues exceedingly brisk, dealers anticipating a rise as the result of the formation of the syndicate of wire nail makers. Recent tenders asked for by the Breslau Railway Board show that fairly remunerative prices are being obtained for finished iron. For round and flat iron the quotations varied from 142s. to 150s. at the works, and for square iron from 142s. to 177s. The Hanover Railway Board have recently ordered ten three-coupled tender locomotives. The cheapest offer was made by Henschel, of Cassel, at £880 on the rails at Cassel; the Vulcan Company, Stettin, asked £942; Egerstorff, of Hanover, £972; Schickau, of Elbing, £1,040; and Schwartzkopf, of Berlin, £1,150. Amongst the tenders for the supply of 670 tons of fire grate bars, the Peiner rolling mill obtained the contract at 94s. per ton, whilst for 515 tons of sheets, the Hörde Company were successful at 143s. per ton. It is interesting to note that amongst the tenders was one for the supply of 820 tons of rolled iron, for which the price of the rolled iron syndicate is now from 125s. to 129s.; but the order was obtained by an outside firm at 121s., thus showing that the syndicate is not so all powerful as might be supposed.

TEXTILES.—According to reports from Thuringia, the manufacturers of hosiery goods and fancy articles in that district are still well employed, and have plenty of orders on hand. Trade is very brisk, and many factories are working night and day in order to get out new patterns and samples. The favourable condition of this branch of the Thuringian industry is exciting competition from French, Belgian, and Austrian manufacturers, and some works in France are introducing the manufacture of knitting machines into that country. In Saxony, the most important district for knitted goods, business is also exceedingly brisk not only in the textiles themselves, but also in the machinery required to produce them. Within the last week or so there was quite a concourse of foreign buyers of textile machinery at Appolda, and orders have been booked from Spain, Sweden, Italy, Switzerland, and even Portugal. The agent of a Spanish firm has also succeeded in persuading some foremen and skilled knitters of that district to enter their works in Spain, and there develop that industry.

THE GERMANS IN ITALY.—German traders are seeking to turn to their own profit the block in the harbour of Genoa. The long delay in discharging a cargo, due to insufficient accommodation, has become a source of great irritation and annoyance to English ship owners, who have resolved to largely increase their rates till the evil is remedied. This circumstance affords an opportunity to German exporters trading by the way of St. Gothard, which will not be allowed to slip by unused.

EXPLOSIVES.—A new kind of explosive has been brought out by Messrs. Grüne & Co., of Unterluess, near Hanover. This firm has for a long time been engaged in the preparation of fossil meal for various industrial purposes, and they have now succeeded in effecting considerable improvements in the explosive known as fossil meal dynamite. Water is said to have no influence on this new explosive. Cartridges charged with it when placed under water still retain their explosive power; they can be placed without the slightest danger in warm water so as to prevent freezing, and frozen cartridges can also with equal safety be put into warm water to be thawed. Direct blasting under water is possible, even if the cartridges have been exposed for months to the influence of the water. The firm have patented a fossil meal cartridge in substitution of the usual cartridge case.

ALUMINIUM.—A factory has been erected in Upper Silesia for working Dr. Walter's patent for the manufacture of aluminium from silicate of alumina by means of electrolysis in cold solution (not in the electric furnace, as on Cowles' plan). It is expected that this process will bring about a considerable reduction in the price of aluminium.

VIENNA, 6TH FEBRUARY, 1888.

THE COAL MARKET.—The condition of the coal market during the past week has not been very active, this being partly due to the warmer weather. It is very probable that the winter coal season will not terminate very satisfactorily, since the sugar campaign was short, and other industries in which large quantities of coal are generally used have greatly suffered through the war scare and the interruptions of railway traffic.

THE IRON MARKET.—There has been no important change in the condition of the iron market during the past week, and the fluctuations in the prices of other metals, and particularly of copper, do not influence that of iron; the price of copper, however, has slightly decreased. The stocks of iron in Austria-Hungary are small, and orders are expected to be booked shortly. In Hungary the unfavourable weather has greatly interfered with business, whilst in Bohemia the market is quiet, and the sale of cast iron goods and enamelled ware is less than what had been anticipated. Nevertheless, manufactories and works are well employed, the articles most in demand being weighing scales and weights, which are being manufactured in large quantities in consequence of the new law regarding periodical revision of weights and scales. The formation of a union of wire nail makers is very probable, whilst the axle tree union has been prolonged to the end of 1889. The balance sheets of the large iron works and companies for the past financial year have not yet been published, but it is hoped that the results will be more favourable than in 1886.

TEXTILES.—The condition of all branches of the textile industry during the latter half of January was more unfavourable than in the first half. Purchases were only made for immediate requirements, in consequence of the unsettled political circumstances, and wholesale merchants, in spite of the peaceable assurances of the Ministry, limited their transactions. The business in bleached cotton yarns, shirtings, &c., is not very brisk; but in printed cotton goods trade is somewhat better, and fairly large sales are taking place in woollen goods and prints. Considerable transactions are expected to take place in the cloth branch, and particularly for military purposes, as soon as navigation is resumed on the Danube, when the buyers from Southern Hungary appear in the market.

A NEW MICROPHONE TRANSMITTER.—Messrs. Siemens and Halske, of Vienna, have just patented a new microphone transmitter, in which the loose contacts consist of hollow carbon cones placed within each other. The object of this arrangement is to facilitate a change of the surfaces in contact, and prevent deterioration under the influence of the current.

THE NEW AUSTRIAN PATENT LAW.—Although improvements in the law for protecting inventions are very badly wanted in Austria, it will yet be some time before the law is altered. The Patent Office is under the control of the Ministry of Commerce, where the project of a new patent law has been elaborated; but before it can come into Parliament the Ministry of Justice must pass and if necessary amend it, so that the new law shall not cause difficulties with existing Acts and with the general principles of the law. After the two Ministries have thus elaborated the Bill in Austria, it must be sent to the Hungarian Government, where it will again be amended, so as not to clash with the different regulations referring to Customs tariffs and trade between the two sections of the empire. The process of transfer and amendment between these various authorities is likely to be a long one, so that English inventors should not place too much confidence in the prospect of speedily enjoying the benefit of a better Austrian patent law.

BRUSSELS, 7TH FEBRUARY, 1888.

THE COAL MARKET.—There is a good deal of business being done in the coal market, which is still firm. Unscreened household coal has risen slightly since my last report, the rates now being from 8s. 9d. to 10s. 5d. Coke is in good demand. The collieries of Sars-Longchamps, of La Louvière, and of La Paix have amalgamated, whereby their interests will be considerably advanced. The profits of the Unis Ouest de Mons Collieries for the past year amount to £28,000. The Produits du Flènu Colliery have renewed some important contracts at an advance of 10d. per ton. The briquette industry has been making great headway since it was first introduced at the Pâturages-Wasmes Colliery, with the object of utilising refuse coal. The machinery employed in Belgium for making briquettes allows of their being manufactured in any form. The Société de Gilly have now installed one of these machines, and Messrs. Zimmermann & Henrez are erecting an additional one.

THE METAL MARKET.—There is little change in the iron market, and the following rates are being quoted: Girders, 96s. to 100s.; angle iron, 104s.; merchant bars, 89s.; No. 2 sheets, 116s.; No. 3, 132s.; No. 4, 176s. The price of pig iron is maintained. Some of the works are busy pushing forward material for the Exhibition. The result of the last State railway contracts is that La Métallurgie gets ten first and second class carriages at £2,754, and £2,670 respectively, and fifteen light carriages at £4,016; La Franco-Belge, twenty third class carriages at £2,060; Nicaise & Delaive, twenty third class carriages at £2,056; Morlanwelz, twenty third class carriages at £2,052; and Seneffe twenty third class carriages at £2,059. The contracts of the economic railways have resulted in Halot Frères, of Louvain, obtaining thirty trucks at £74 each; La Franco-Belge, seventeen luggage vans at £147 each, and five at £149 each; La Dyle, seventeen luggage vans at £147; and Verhaegen twenty first class carriages at £204 each. Important orders have also been given to Hiart, Bailly, and Germain.

THE GLASS TRADE.—The market continues very quiet. The convention for England having ceased to exist, the rates for the market are 19s. for coarse, 21s. for fourth, and 23s. for third quality. The attempts at conventions have merely served to place the trade in a worse plight than it was in before. The accounts which have been published in England respecting bottle making by machinery have caused a good deal of interest in the Charleroi district.

SYNDICATE OF ELECTRICIANS.—It is proposed to establish an electrical syndicate here, but there will be some difficulty in arriving at a proper understanding as to the share each firm is to have of the business which comes in. One of the main objects for which the syndicate is being formed is to light the town by electricity, and in order to do this it is proposed to buy up the gas works. Failing this, which would cost some millions of francs, a central station would be established to supply the electric light to the principal establishments in the business part of the town. The syndicate also intends to acquire the most important electrical patents, so as to put down outside competition. The project is very good on paper, but whether it can be realised is another matter.

THE DEVELOPMENT OF THE TELEGRAPH IN BELGIUM.—The first telegraph line in Belgium was established in 1846, between Brussels and Antwerp, and was worked by Messrs. Wheatstone & Cooke, under license from the Government. There were offices for the public at Brussels, Malines, and Antwerp. The line was taken over by the State in 1850, in which year a law was passed making telegraphs a State monopoly, and authorising the establishment of telegraph communication on all the railway lines.

Digitized by Google

On the 15th March, 1851, State telegraph offices were opened to the public at Brussels, Malines, Antwerp, Ghent, Ostend, Liège, and Verviers, and the Belgian lines were connected to those of the Austro-German Telegraph Union. On the 6th May, 1853, communication with England was established. At the end of 1853, there were in Belgium 406 miles of lines, comprising a total of 1350 miles of wire, and forty-two telegraph offices; while 52,050 telegrams were transmitted in the course of the year. Since that period the whole country has been covered with a network of wires, the number of offices open has risen to 870, and the annual number of telegrams to over 4,000,000.

DÜSSELDORF, 6TH FEBRUARY, 1888.

THE IRON MARKET.—The characteristic features of the iron market are still great activity and rising prices. The tendency of crude iron to advance in price persists, in spite of influences which might be expected to operate strongly against it. Forge pig is much sought after, and from 1s. to 1s. 6d. a ton above syndicate prices is willingly paid for it. Other sorts are in strong demand. The spiegeleisen syndicate has fixed the rate for 10 to 12 per cent. manganese at 58s., but 59s. has been paid this week on the Siegen exchange. A brisk business is being done in Bessemer and basic steel pig at rising prices. Dealings have taken place for delivery at the end of June. Thus the business of the crude iron makers is assured for the first half of the current year. The home demand for finished iron and steel exhibits no tendency to abate; but the export trade, thanks to the high prices, is steadily shrinking. Such business as is transacted yields but little profit. Home consumers are growing alarmed at the aspect affairs are assuming, and there is talk of invoking the authority of the Government to aid in putting an end to the syndicating process, which threatens to involve every branch of the industry. The latest Cologne prices are as follow: Spiegel pig, 58s.; Rhenish-Westphalian forge pig, 53s. to 54s.; Bessemer pig, 53s.; Luxemburg white forge, 38s.; German foundry pig, No. 1, 57s.; merchant bars, £6. 2s. 6d. and £6. 5s., according to quantity; angles, £6. 12s. 6d. and £6. 15s.; joists, £5. 18s. and £6; boiler plate, £8; Siegen II K plate, £7. 8s. and £7. 11s. for three months bill, or with 1½ per cent. discount for cash.

THE EXPORT IRON TRADE.—The Customs returns just issued will afford German manufacturers matter for serious reflection. Merely comparing the total amount of business transacted with foreign customers in 1887 with that of the preceding year, we arrive at a satisfactory result, for there is an increase of over 4 per cent.; but when the business of the year is reviewed month by month, there is abundant cause for regret and apprehension. Thus, for example, the exports of iron in the first quarter of the year were greater than those of the corresponding quarter of 1886 by 13·86 per cent. By the end of the second quarter the increase revealed a tendency to shrink, being at that date 12·05 per cent. The contraction proceeded more and more rapidly, so that the increase appeared at the end of the third quarter as 8·18 per cent., and at the end of the year as 4·14 per cent. only. This shrinkage corresponds with the rise in prices, of which it is doubtless an effect. The later months of the year compare unfavourably with those of 1886. The life and vigour which characterised the trade of the early months appear to have died out. There is a clearly marked tendency to further shrinkage, which renders the prospect cheerless. The following are the quantities exported in 1887, compared with those of 1886: Pig iron, 212,294 (250,681) tons, a loss of 15·3 per cent.; scrap iron, 60,548 (52,236) tons, a gain of 15·9 per cent.; half finished iron and steel blooms, ingots, puddle bars, &c., 40,135 (42,401) tons, a loss of 5·3 per cent.; finished iron and steel bars, angles, plates, &c., 292,099 (251,192) tons, a gain of 16·3 per cent.; wire, 242,553 (238,498) tons, a gain of 1·7 per cent.; rails, 174,226 (163,222) tons, a gain of 6·7 per cent.; other railway iron, 42,000 (35,417) tons, a gain of 8·6 per cent.; and manufactured goods, other than machines, 196,441 (176,515) tons, a gain of 11·3 per cent.; total exports of iron of all sorts, 1,260,296 (1,210,162) tons, a gain of 4·14 per cent. The trade of the last month of the year shows, compared with that of November, an increase in wire, plates, wrought iron pipes, and scrap; but in all other goods there has been a falling off.

LINEN YARNS.—The latest report received from Bielefeld describes the market as very animated for tow yarns and linen yarns. A large amount of business has been transacted at full prices.

LILLE, 7TH FEBRUARY, 1888.

TEXTILE MANUFACTURES.—The week just ended has been a period of great activity in the linen trade of this locality. A hopeful feeling has shown itself among manufacturers at Armentières, who have received with pleasant surprise renewed orders from customers who had bought largely at the beginning of January. The prospect is steadily improving all round. If weavers could get a substantial advance in prices, now more than ever needed since yarns have become dearer, the situation would be fairly good. There is a little more animation in the foreign trade, and hopes are entertained that the demand for export will now increase. During the year 1887, the export trade in linen and hempen goods fell off heavily, the total declared value for that year being only £318,840, against £532,160 in 1886. The value for the year 1880 reached £1,119,880. At Roubaix business is slowly reviving. The market is quiet for combed wool, and prices remain unaltered at about 5 francs per kilogramme for South American; but there is a brisk demand for "noils" at full prices. There is more animation in the market for woollen fabrics, a steady course of business giving rise to hopes of continued activity. Dulness is the characteristic feature of the market for raw silk at Lyons. Silk stuffs exhibit scarcely more animation. The business done is chiefly on Paris account. London agents have bought smooth black stuffs, but only after much bargaining over the prices. There is nothing doing on American account. The Calais tulle trade is beginning to revive. American orders in this line come to hand freely, and as the season has commenced a month earlier than usual, the prospect is cheering. The Calais manufacturers are making arrangements to provide an imposing display of their goods at the great Exhibition next year.

FLAX AND YARN MARKETS.—For flax the general situation has not changed since my last report. Home grown remains in strong demand, and a large amount of business has been done at full prices. A considerable shrinkage has, however, taken place in Russian flax, consumers having provided sufficiently for present wants. Our market here is still favourably influenced by the strong tone of affairs at Ghent, where Irish buyers are dealing largely in home grown flax. There is not much doing in Russian tows, but French, Belgian, and Dutch are in good demand for export. Business in yarns continues active, and prices are very firm, the finer numbers being scarce. The foreign demand is brisk, but not quite so strong as it was a few weeks ago. The total value of the exports of flax and hemp yarns in the year 1887 amounted to £412,360, against £242,400 in the previous year. The demand for jute yarns remains unabated.

WINTERTHUR, 6TH FEBRUARY, 1888.

STEAM AND HYDRAULIC POWER IN SWITZERLAND.—In one of my previous letters, I gave details of a scheme elaborated with a view to obtain additional water power from the river Limmat, by the erection of a weir near Baden. This scheme has been opposed by the Cantonal Government of Zürich, on the ground that it would interfere with navigation and injure existing fishing rights. During the discussion of the project, some interesting figures have been brought forward with reference to the total amount of mechanical power now in use throughout Switzerland. It appears that there are 3500 workshops or mills coming under the Factory Act. The total number of hands employed in these is 150,000, and the total power 68,000 h.p., of which 18,000 are supplied by steam and the rest by water. There are throughout Switzerland about 2600 stationary steam boilers. In addition to the stationary engines and boilers, there are six hundred locomotives, representing a total of 175,000 h.p., and the annual consumption of coal and coke in Switzerland is about 787,000 tons. The satisfactory result of the trials recently made with the plant for transmitting water power from Kriegstetten to Solothurn has given a further impetus to electrical engineering, and caused quite a number of projects to be put forth for utilising some of the water power now running to waste.

THE MANUFACTURE OF ALUMINIUM.—Since the original project for the establishment of a large aluminium factory on the Rhine near Schaffhausen was abandoned, owing to a universal protest throughout the country, the promoters are now coming forward with a scheme on a reduced scale, and a company has been formed under the title the Swiss Metallurgical Company of Neuhausen, with the object of establishing works in the town for the electrical production of aluminium and other metals. The total share capital is only £8,000, divided into forty £200 shares.

MADRID, 6TH FEBRUARY, 1888.

IRON ORE MINES.—Some English speculators lately examined the iron ore mines of the Pedroso Company, but came to the conclusion not to enter into a contract to carry on the working of the mines. The company has since then stopped payment. It was established in 1817, but never proved remunerative to the shareholders, all the profits having been devoted to fresh purchases of land and plant. The liabilities amount to nearly £240,000, while the assets, including 35,000 acres of land, are estimated at about £70,000, exclusive of the value of the mines and stock. Most of the shares of the company are held by a well known Seville house, which has, in consequence, stopped payment also.

THE CADIZ ARSENAL.—La Carraca Arsenal, in the Bay of Cadiz, will probably be transferred by the Government for twenty-five years to a private company, which is to be formed under the auspices of the well known Barcelona company, La Maquinista Terrestre of Maritima. The terms suggested are very favourable to the Government. It is proposed to make considerable improvements in the arsenal, which will be left for the benefit of the Government on the expiration of the period of the contract, on condition that a ship is to be ordered from the company whenever one is built at the Government establishments at Carthagena and Ferrol. Ships will be built by the company at the estimated cost of similar ships built simultaneously in the Government yards.

TIN PLATE WORKS.—Although it is only a few months ago since Messrs. Goitia & Co., of Beasain, started the first tin plate works in Spain, they intend establishing another at Bilbao. They will manufacture at Beasain real charcoal plates of superior quality, and a cheaper article at Bilbao. A high duty is payable on tin plates; but the home market is too small even for only two works, so that it looks as if the firm had some hopes of being able to do an export trade to neutral markets at present supplied by English makers.

NEW YORK, 28TH JANUARY, 1888.

THE COAL MARKET.—The condition of the anthracite coal market is practically unchanged. There has been no progress made towards settling the miners' strike. One of the latest signs of the intentions of the Reading Railroad is that President Corbin will in a few days issue a statement of the business of the Reading Company covering several years, the object being prepared to convince the public that too much of the money received for the coal goes to the miners. This indicates that the officials will insist upon the acceptance by the miners of the 10s. basis of wages. The general opinion is that the strike will be an extended one. Much pressure is being brought to bear upon the Reading officials by business men of Reading and Pottsville to submit the difference to arbitration, but with little if any effect. Meanwhile the Wyoming collieries are being worked to their utmost capacities. Eighty-five per cent. of the present production of anthracite is from the Wyoming region, which has nearly doubled its output as compared with last year. A report is current that the railroad company proposes leasing its collieries to a powerful syndicate, by which means the two businesses would become separated, and harmonious relations might be more easily preserved.

THE METAL MARKETS.—Manufacturers of steel rails continue to report a scarcity of business, but a considerable improvement is expected soon. The price at present is about £6. 10s. There has been considerable activity in copper for March and April delivery, sales from 200,000lb. to 300,000lb. being at 16¾ cents (8¼d.), the total transactions amounting to about 900,000lb., mostly for export. The total production for 1887 was 182,500,000lb., of which about 45,000,000lb. has been exported, and a home consumption of 140,500,000lb. leaves in stock about 27,000,000lb. on January 1st. It is expected that the Calumet and Hecla mine will probably open by February 1st. This means the addition of about 2¼ million pounds of ingot copper per month, and the completion of the three new stamps of the company after March 1st would increase the output to about 5,000,000lb. Should these events come to pass, the output of the mine for 1888 should be 56,000,000lb., as against 45,500,000 for 1887. The most significant point is that the managers would become aggressive opponents of the "bull" speculators. It is not to be expected that prices will fall quickly to the normal figures, and those who are best conversant with the business do not expect an appreciable decline for some time to come. The tin market has been stronger, with a tendency for prices to increase for future delivery. There has been a moderate demand for spelter. Sheet zinc is scarce. There has been very little business in antimony.

LEAD.—The lead produced in the United States in 1887 reached the enormous total of 160,000 tons, but stocks of bullion and refined lead have not increased. The returns from most producers and refiners show that the stocks on hand are small, and including the foreign lead now in store in New York, about the same as at the end of 1886. Manufactured lead stock has probably increased, but is widely distributed. Of this production only 20,000 tons come from non-argentiferous regions. The increase in the production of lead from silver bearing ore is not due so much to the development of any great find as to using a lower grade of ore, this being made possible by improvements in processes and machinery, and to lessening the cost of transportation, smelting, &c. The recent discovery of some promising silver deposits will add more and more to the output of lead during the present year.

ALUMINIUM BRONZE.—At a series of comparative tests of common and aluminium bronze at the Watertown Arsenal, the results were as follow: Ordinary bronze showed a tensile strength of 24,500lb. per square inch, with an elongation of 8·2 per cent. Aluminium bronze, known commercially as "A 3," cast in sand, showed a tensile strength of 53,000lb., and an elongation of 6·2 per cent., while the same metal cast in chilled moulds resisted a strain of 67,600lb. to the square inch, with an elongation of 13 per cent. In the opinion of naval experts it is thought that steel and wrought iron will be displaced to a considerable extent by this metal.

PHILADELPHIA, 28TH JANUARY, 1888.

THE MELBOURNE AND PARIS EXHIBITIONS.—A resolution has been introduced in the House of Representatives to appropriate £40,000 for necessary expenses connected with the representation of the United States in the Paris Exhibition of 1889. While the amount asked for will probably be cut down, the United States will be creditably represented. A Bill to appropriate the amount necessary to represent the United States at Melbourne has passed the House.

EMMENSITE.—Tests of this new explosive have been lately made on the Croton Aqueduct, and by the Delaware, Lackawanna, and Western Railroad, with very satisfactory results as compared with dynamite and other explosives. A large piece of the explosive was put through a stone breaker and reduced from the condition resembling a bar of sulphur to a powder, and a revolver fired into a pile of the powder failed to explode it. It can readily be exploded by a fulminating cap, and is said to have four times the effect of dynamite.

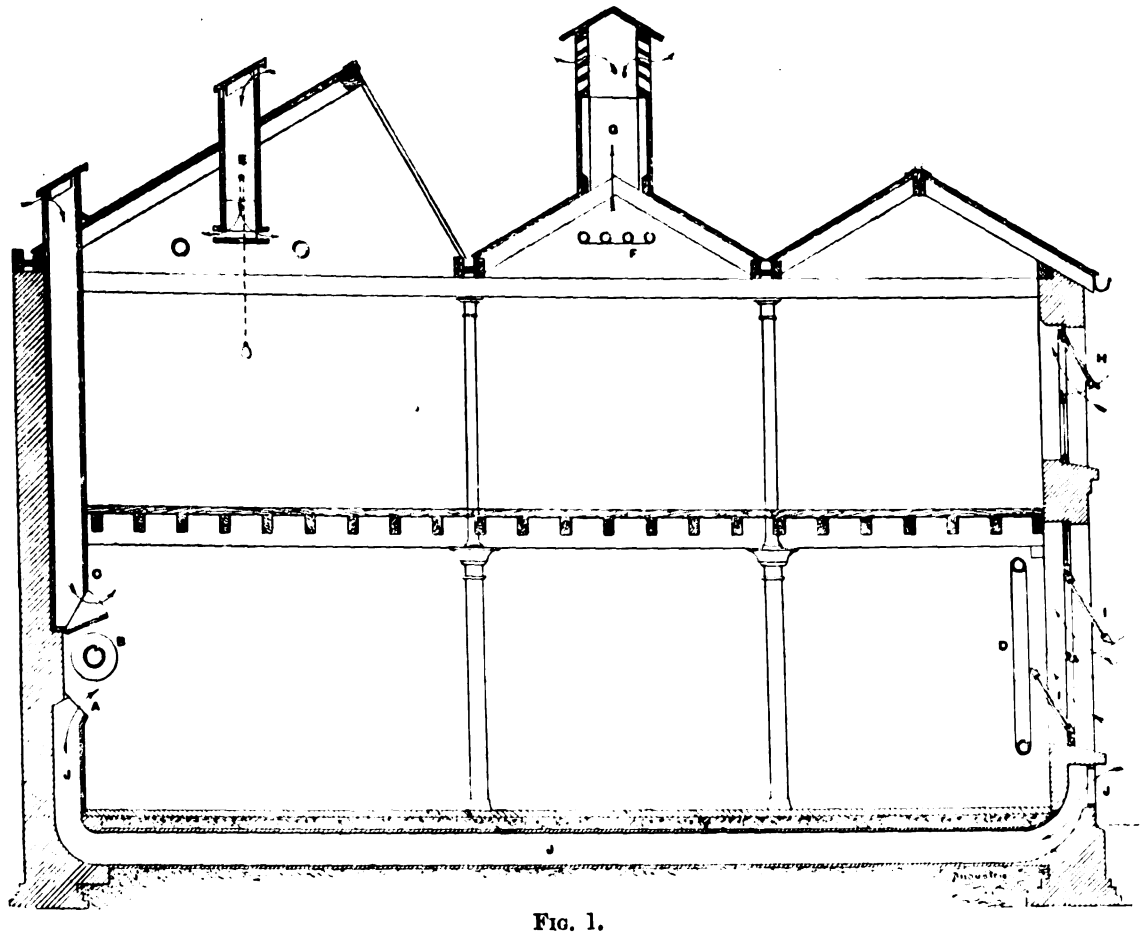
HEALTH IN ENGINEERING WORKSHOPS.



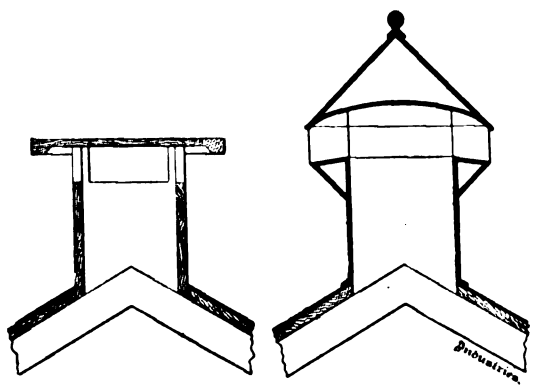


FIG. 1.

THE ECONOMY OF HEALTH IN ENGINEERING WORKSHOPS.*

THE author of this paper, in commencing, referred at some length to the importance, even on the ground of the self interest of the employer, of a workman being kept in good health, and said that the healthier workman is the more contented workman, that the healthier workshop is the more comfortable workshop, and therefore that a workshop which gets a repute among workmen for being more comfortable than others, and filled with more contented men, will always be sought after by the most thoughtful and valuable hands, so that the employer can have his choice of men without paying more than standard wages. He divided the subject into four departments: (1) Ventilating and Heating; (2) Lighting by Daylight or Artificial Light; (3) Water Supply, Dining Rooms, &c.; (4) Sewering and Waste Appliances. He stated

FIGS. 2 AND 3.

that each man should have at least 25 sq. ft. of floor area and at least 400 cub. ft. of space for comfortable ventilation. The volume of fresh air required per man per hour is not less than 1000 cub. ft., even in cold weather and with inactive employment, and four to ten times this amount is required for laborious work in warm weather. This minimum ventilation would have to be increased in warm weather, say by opening a window. In hot weather both window and door might be widely opened, and a moderate breeze through them would feel perfectly pleasant. It was pointed out that dependence on the wind or the rise of temperature in the room was fallacious, and that the whirligigs and cowls worked by the wind were most active when least wanted, and *vice versa*. For the purpose of being independent of the wind, all vent shafts should be well raised above the roofs like chimneys, and be roofed over and protected from rain, either by louvres on all sides, a flat top with side openings, or a circular double cone outlet, as shown in Figs. 1, 2, and 3. Each form mentioned allows the wind to blow through without materially affecting the draught. One important rule as to outlet ventilators is to have only one for each room, unless for rooms of great size; because if there are two or more outlets some of them will at times act as inlets, and thus reverse the intended currents. But even with one outlet there are circumstances which will reverse the current sometimes, so it is well to arrange for preventing back draughts causing inconvenience by a screen board arranged as at F (Fig. 1). No specific rule can be given for the size of outlet ventilators, but it may be stated that at least 12 sq. in. per man should be provided, and for hot work much more; the inlets being of similar area. Air inlets should be as numerous as circumstances permit, and arranged to disperse their draughts as widely and gently as possible. Of course windows offer the readiest means of inlet, and they should have many small opening casements hung so as to turn their draughts upward; several small casements causing less apparent draught than one large one, by their small currents dispersing into the air more readily. In Fig. 1, H and I show some good forms of casement, and in all such it is well to fix stop chains, or have short racks to prevent their being opened to more than about 30° pitch, for if opened more they often cause down draught. Air inlets through walls should always have deflectors to disperse their draughts. If no men work close to them, the best plan may be a simple flat board or plate fixed a few inches off the wall, so as to turn the draught out at all sides, as at M, in Fig. 5, the draught being turned from the face of the wall by a taper shaped casing. Where external appearance is no great object, the best weathering for an air inlet is simply a piece of glazed tile pipe, built with a slight outward slope into the wall, and projecting a couple of inches, as at O (Fig. 5); but the most efficient and neatest arrangement, where available, is to have a projecting shield, as at K, with openings on all sides of from 1¼in. to 3in. wide, not liable to get choked with dust; the shield protecting the inlet from gusts of wind. All these forms of inlet should have regulators, to fix them open more or less, or to close them. Sometimes it is well to have fixed ventilators giving the proper minimum amount of inlet and outlet, and have also supplementary openings for increased ventilation when desired. For extensive top lighted rooms, similar to loom sheds, it is necessary to bring in the fresh air from the roof, so as to reach all parts of the room. This can best be done by air tubes hanging down a few feet below the roof, and with dispersing boards below them, as at E. In dealing with a very broad room with other rooms over it, the equalisation of the air can best be effected by having the air outlet at the centre and the inlets round the sides, and some of these inlets may be brought down, as shown at C, through an upper storey; but as this plan tends to induce reversed currents, it is better, where possible, to bring the air by large tubes J below the floor from the nearest convenient open area. Air can be led up or down, round corners, or through big or little holes, in fact in any imaginable way, if a balance of tendencies in the required direction be arranged. In workshops such as are used for smith's work, with raised louvres along the ridges of each roof, the best means of regulating the ventilation is by light wooden doors, hung so as to close, or partly close, the opening just below the raised louvres, as shown at P, Q, and R, in Fig. 4. Such doors are cheaper than pivoted louvres. Smithy doors are often made in two heights, to aid ventilation; but a better plan is to have a second door hung just within the room, formed entirely of ventilating louvres, so as to turn the draught upward. A screen board may be hung over the lower part of the door when only moderate ventilation is required. Having referred to outlets depending on the heat of the room or the wind for their action, artificial means of ventilation was next dealt with. Heat applied in some suitable manner is the most constantly available power for artificial ventilation. It can be applied by a fire or gas burners; but a much safer plan is to put a coil of steam or hot water pipes below the up cast flue, as at F (Fig. 1), so that the most heat may be supplied in hot weather, and the least in cold weather. The best of all known means for inducing and regulating the ventilation of workshops are fans driven by power, which are easily applied; 1 i.h.p., under favourable conditions, will drive 12,000 cub. ft. of air per minute, or 720,000 cub. ft. per hour, in and out of a workshop. There is now no excuse for ill ventilated workshops, for all the risk of back draught, and the irregularities and contrarieties of wind ventilation, are overcome by the power fan, which will give as much or as little air as required by the

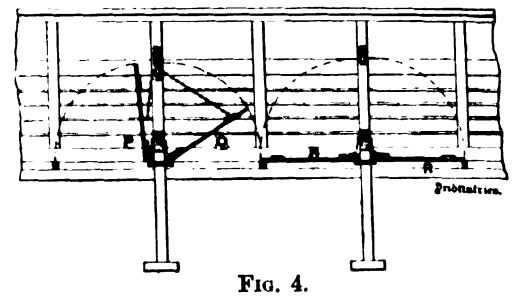

FIG. 4.

simple regulation of its speed. The fan should be fitted to the outlets, which should be of the form described and vertical. The speed of the fan may be regulated by stepped pulleys, like a lathe, or by cone pulleys and belting, or by curved cone friction pulleys, like a potter's wheel. In selecting a ventilating fan, the specially light work should be remembered, the best forms having very large airways throughout, with little frictional surface, fine cutting edges, and truly curved vanes, so as to lightly pass a great bulk of air, the Blackman propeller being one of the best for this purpose. Steam or air jets drawn from steam or air pipes can be used, and although the outlets need not be so large as those recommended for natural ventilation, it is well that the sizes of outlets and shafts, &c., should be arranged for an air speed not exceeding 600 lineal feet per minute. The inlets should, if convenient, be arranged for a speed of about 200ft. per minute, to avoid strong draughts. So far as heating apparatus is concerned, hot water or steam pipes of large diameter, or steam pipes of small diameter, could be used; but the heating pipes should be looped or fitted with "gills" or flanges, as at B (Fig. 1), and it is well to counteract the cooling effect of large windows by loops of heating pipe round them. The author advocated ample light for shops, and recommended either thick sheet or rough plate glass for daylight lighting; and pointed out that good gas burners were essential, alike on account of the better combustion

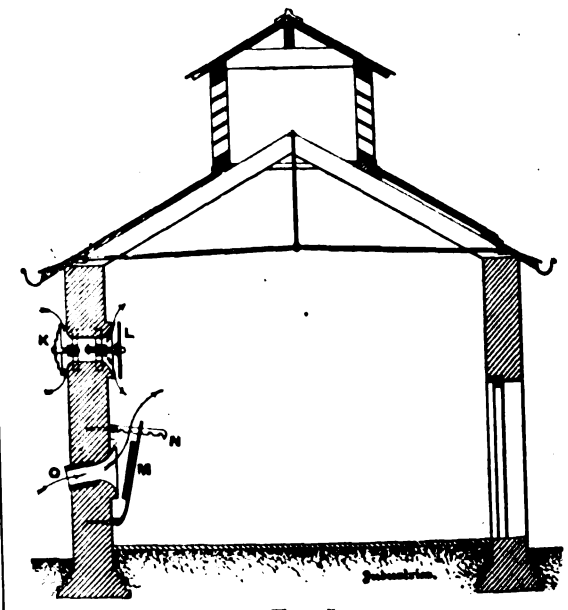

FIG. 5.

and of the effect of bad light on the sight. If each man has one gas burner, five-fold ventilation should be used whenever the gas is lighted. The electric glow light seemed to be the best for nearly all lighting purposes, the arc light being as yet too unsteady for long continued use. The author recommended that better attention should be given to the question of providing a comfortable dining room, and thought the provision of washing accommodation was also advisable. He then pointed out how badly kept the sanitary conveniences were in most workshops, and thought the right policy was to encourage habits of cleanliness and decency everywhere, and not risk a man's health and offend his decency through having defective closets. If tub closets are used, care should be taken to avoid leaky tubs, and to fit them closely up to the seats. The floor of cement or flagging should be well sloped to a gutter, and the partitions should be kept 6in. above the floor, to facilitate washing. Trough closets are the cleanest and best apparatus where sewers are available. Those made of strong earthenware, with seats like thick rounded pipe ends, and with self discharging syphon flushing cisterns, are thoroughly satisfactory, and give little trouble. Privies with middens are unsuitable for works, but where used should have the midden protected from rain and drained, so as to be as dry as practicable, and thus prevent

* Abstract of a paper read before the Manchester Association of Engineers, by Mr. J. Corbett, 25th January, 1888.

Digitized by Google

putrefaction. The walls of all such places should be lined with brown salt glazed bricks, or else well painted in dull colours. Glazed white bricks are better, but fully twice the cost. Ample light and ventilation, without due exposure to the weather, are, of course, needful for health and comfort. Urinals are best faced with slate, on account of its impervious and smooth surface. Flags or brick walls should be well coated with pitch, laid on hot, to form a good surface, and this can easily be renewed when necessary. The waste grids and surface water grids should all be set in stone or earthenware dishes, with glazed earthenware "gullies" or traps underneath. Iron traps are objectionable on many grounds. Of course, no sewer opening at the surface should be left untrapped, for if so, dangerous gases may escape and do injury. Other points were dealt with, after which the author said that by proper attention to health in the workshop any man now working in an uncomfortable and unhealthy shop might be made at least 1 per cent. abler, more active, and more efficient in his work. Taking an average workman to be worth £100 a year to his employer, this at 1 per cent. is £1 per year, or equal to £20 of capital; and as all that had been suggested would not cost £20 per man—in most shops not £5 per man—on the low ground of mere money value, and on the high ground of duty, employers must be convinced that the subject of his paper was truly called "Economy of Health in Workshops."

ENGINES OF THE S.S. "CITY OF BERLIN."

On page 140 of our present issue, we give an engraving illustrating the triple expansion engines recently constructed by Messrs. Laird Brothers, engineers and shipbuilders, Birkenhead, for the s.s. "City of Berlin," belonging to the Inman and International Steamship Company, Limited. This vessel, which was built in 1874 by Messrs. Caird and Co., of Greenock, has had not only new engines and boilers fitted, but has been completely renovated throughout. This vessel has the following dimensions: Length over all, 510ft.; length between perpendiculars, 488ft.; moulded width, 44ft.; depth to spar deck, 37ft.; depth to tonnage deck, 19ft. The vessel is four decked, with a gross measurement of 5490 tons, and a registered tonnage of 3139 tons. The new engines, which we now illustrate, are, as we have said, of the triple expansion type, with cylinders having diameters of 41in., 65in., and 101in. respectively, the stroke of each piston being 66in. A trial trip was made on the 22nd and 23rd December last, when the following satisfactory results as regards the engines were obtained: With the boilers working under natural draught, and the steam pressure 129lb. per square inch, the engines indicated, when running at 58½ revolutions, 4171 h.p.; under forced draught, while the steam pressure was easily maintained at 152lb. per square inch, the engines indicated 6025 h.p., while running at 66½ revolutions per minute, and with a vacuum of 25½in. As deduced from the indicator diagrams, the total horse power was proportioned between the three cylinders as follow: High pressure cylinder, 1963 h.p.; intermediate cylinder, 1885 h.p.; low pressure cylinder, 2177 h.p.; making a total of 6025 h.p. The total space occupied by the engines does not exceed that taken up by the old engines, although the power is now increased by over 20 per cent. The steam is supplied by eight boilers of the cylindrical return tubular type. They are of steel, and have an ordinary working pressure of 150lb. per square inch. Each boiler has three furnaces, and has been tested in conformity with the Board of Trade requirements to 300lb. per square inch. The total grate surface is 324 sq. ft., and the total heating surface 14,616 sq. ft. This gives a ratio of 18·6 i.h.p. per foot of grate surface, and ·413 i.h.p. per square foot of heating surface. An evaporator is fitted in the engine room to provide for waste, which is capable of producing 15 tons of fresh water per twenty-four hours. The crank and propeller shafts are of Whitworth's fluid compressed steel. The space taken up by the boilers is so much less than that formerly occupied by the old boilers that a gain of six first class state rooms on the main deck, and officers' cabins on the upper deck, have been obtained, besides an additional space for cargo. The consumption of fuel being smaller per horse power, less space is, of course, required for coal bunkers. Howden's system of forced draught is used, the air being supplied by four centrifugal fans, driven by independent engines. Circulating water for the condensers is supplied by two Tangye pumps, which are worked by a separate pair of engines. There are also fitted Worthington engines and pumps to feed the main boilers, and to supply water for fire and sanitary purposes. The vessel is illuminated throughout by means of electric lamps, electricity being supplied by a duplicate set of Messrs. Clarke, Chapman, & Parsons' engines and dynamos, each set being capable of supplying the whole of the lighting, so that there is no possibility of failure. The heating and ventilating arrangements of the ship have received special attention, fresh air being brought into every division by cowl ventilators from above, which communicate with fore and aft trunkways. Utley's patent ventilating side lights are also used, and can be opened in all weathers. The heating arrangements consist of an elaborate system of radiators. The steam for heating purposes, after passing through the various compartments, is conveyed back to an auxiliary condenser, and the water is returned to the boilers. The ship's hull has been thoroughly overhauled, and the upper and main decks plated. Additional water tight bulkheads have also been fitted. The rig has been altered from the old ship rig of the Inman Company to that of a three-masted schooner, which gives the vessel a much lighter appearance as regards her rigging. In addition to the number of boats required by the Board of Trade, three collapsible boats have been fitted, two made after Berthon's and one after Chambers' patented principles, each being capable of accommodating about one hundred passengers. Fire extinguishing apparatus is also supplied throughout the vessel. With the extensive alterations that have been made, the owners consider that the vessel is now not only faster and handsomer, but also much stronger than when first built.

Notices of Meetings.

THIS WEEK.

Society of Arts.—Friday, 10th February, 8 p.m. Indian Section. Paper to be read on "The Work of the Afghan Frontier Commission," by Captain Manisfold, R.A.

Royal Institution of Great Britain.—Friday, 10th February, 9 p.m. Lecture on "Safety Lamps in Collieries," by Mr. W. H. Preece.—Saturday, 11th February, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

Royal United Service Institution.—Friday, 10th February, 3 p.m. Paper to be read on "The Practical Value of the Kriegspiel," by Captain H. S. Wilkinson.

Physical Society.—Saturday, 11th February, 3 p.m. Paper to be read on "The Limit of Refraction in Relation to Temperature and Chemical Composition."

NEXT WEEK.

Society of Arts.—Monday, 13th February, 8 p.m. Cantor lecture on "Yeast: its Morphology and Culture," by Mr. A. Gordon Salomon, F.I.C., F.C.S.—Tuesday, 14th February, 8 p.m. Applied Art Section. Paper to be read on "Principles of Design as Applied to Bookbinding," by Mr. Henry B. Wheatley.—Wednesday, 15th February, 8 p.m. Ordinary meeting. Paper to be read on "Type Writers and Type Writing," by Mr. John Harrison.—Thursday, 16th February, 8 p.m. Special lecture on "Etching and Mezzotint Engraving," by Professor Hubert Herkomer, A.R.A.

Institution of Civil Engineers.—Tuesday, 14th February, 8 p.m. Ordinary meeting. Paper to be read with a view to discussion, "The Economic Use of the Plane Table in Topographical Surveying," by Mr. Josiah Pierce, jun., M.A., Assoc.M.Inst.C.E.

Royal Meteorological Society.—Wednesday, 15th February, 7 p.m. Papers to be read on "Electrical and Meteorological Observations on the Peak of Teneriffe," by the Hon. Ralph Abercomby, F.R.Met.Soc.; "Rainfall of South Africa, 1842-1886," by W. B. Tripp, M.Inst.C.E., F.R.Met. Soc.; and "Some Methods of Cloud Measurements," by Nils Ekholm.

Civil and Mechanical Engineers' Society.—Wednesday, 15th February, 7 p.m. Paper to be read on "Sea Water for Street Watering," by Mr. S. Hardy Terry, M.Inst.C.E., M.Inst.M.E.

Royal Institution of Great Britain.—Friday, 17th February, 9 p.m. Lecture on "The Development of English Pottery," by Sir H. Doulton.—Saturday, 18th February, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

Architectural Association.—Friday, 17th February, 7-30 p.m. Ordinary meeting. Paper to be read by Mr. W. H. Bidlake, M.A.

Royal United Service Institution.—Friday, 17th February, 3 p.m. Paper to be read on "The Advantages of a Simple Drill Nomenclature Consistent for all arms, apropos to an incident of the Battle of Tel-el-Kebir," by Colonel J. F. Maurice, R.A.

PRICES CURRENT, 9th February.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—We have very little new to report. Chili bars have been sold during the week at £74. 2s. 6d. to £76. 12s. 6d. for sharp cash parcels. Quotations for manufactured are unaltered, and very few orders are coming forward.

Tin.—The advance has been maintained, and at £170 per ton a fair business has been done in Straits sharp cash parcels; for forward delivery £145 is quoted.

Lead is much firmer and higher prices ruling.

Spelter.—Quotations are easier, with very little business doing.

HOME INDUSTRIES.

MANCHESTER, 9TH FEBRUARY, 1888.

THE ENGINEERING TRADE.—The engineers of the district are finding a little more work, principally on foreign account; but in almost every case they could easily undertake a great deal more if it could be obtained. Messrs. Goodfellow & Matthews, of Hyde, are very busy, and are in this respect better off than most of their neighbours. Millwrights are only moderately employed, and can hardly expect any great improvement until there is another move towards the extension of spinning concerns. Tool makers are finding both inquiries and orders more numerous, but the tendency is rather in the direction of orders for specialties than in that of ordinary workshop tools. Boiler makers continue to be well employed, almost without exception, and there is no prospect of a scarcity of orders at present. There is very little call for general iron foundry work, and constructional iron founders especially are poorly engaged. Makers of special soft castings are busy, but as this department supplies special customers, it is no indication of the general state of trade. Coppersmiths and brass founders are suffering largely from the effects of the excessive advance in the price of the raw materials used. For many purposes for which copper has been exclusively used other metals are being tried, and this tendency will have its effect shortly on the copper market. There is a very decided inclination not to use more copper than is possible, and a maintenance of present rates will result in a permanent diminution of the number of its uses. Almost without exception cotton machinists are well under order, and there is also a steady demand which keeps them fully supplied with work. In this department there will be, speaking generally, no lack of employment for some time to come. In spite of this undoubted fact, there is as much cutting down of prices as ever to obtain work, and there is such keen competition that makers are deriving little advantage from the prevailing briskness. Considering that the competition in textile machinery is a purely local one, some advantage ought to be obtained from the present large demand, and to a partial extent at any rate, the pressure of the excessively low prices should be relieved.

A NEW MULE.—Mr. Richard Threlfall, of Bolton, is just introducing a new cotton mule, patented by Mr. Henry Ashworth, which is constructed with two rows of spindles. One row is set so that the points are higher than those in the other, and the spindles are arranged so that there are two threads in 2in., which is equal to an inch gauge of spindles. Special provision is made for working the fallers, but otherwise the whole of the motions are from a headstock of the usual construction. The saving of space from this arrangement is equal to nearly 40 per cent. A further trial will be needed to enable a definite opinion to be passed, but the machine appears likely to succeed.

THE MERCHANDISE MARKS ACT.—The working of this Act has been attended with many inconveniences, and there have been one or two decisions on legal points which show that it is not yet fully understood. It is provided that an offence against the Act may be defined by reference to a trade custom, and as there exists some doubt about the exact operation of this rule, steps are being taken to bring about a meeting of merchants at which certain points should be discussed. In this way it is hoped that trade customs may be distinctly defined, so that it will be easy for the courts to define what is an offence and what is not. It is hoped that the formation of a strong committee will result in advantage to the merchants, by enabling them to protect each other from trivial and vexatious prosecutions, and also to combine for the prosecution of any persons guilty of fraudulent practices. The Chamber of Commerce is therefore to be presented with a requisition to appoint such a committee.

LONDON, 9TH FEBRUARY, 1888.

THE MONEY MARKET.—There is still a great difficulty in finding employment for money, and the absolute flatness of the Stock Exchange helps to retain the exceedingly low rates for loans and discounts, which have now prevailed for some weeks. The stock markets have been completely demoralised by the anxiety resulting from the political tension on the Continent. Last Saturday speculation and investment was absolutely dead, and on Monday the market still waited for Prince Bismarck's speech. On the strength of his pacific declarations prices mended a little, but a relapse set in again. Every species of security was depressed in sympathy with the foreign department. Home railways have mended a good deal, but the anticipated rise in Southern deferred stocks, consequent on the provisional treaty between the Brighton and the South-Eastern lines, has been interfered with by the prevailing depression. Southern railways are, of course, particularly susceptible to bad news from the Continent. Copper shares have not been so good, and the price for the metal itself shows a slight inclination to fall.

COMPANIES.—Since our last report the following new companies have been registered: Farmer, Robey, & Co., Limited, with a capital of £50,000, to purchase the engineering business carried on by Messrs. Farmer, Robey, Brown, & Co., Limited, at Trent Foundry, Gainsborough; Henry Mitchell & Co., Limited, with a capital of £450,000, to carry on business as brewers; the Exploration Company of Central South Africa, Limited, with a capital of £5,000; the Electrical Automatic Delivery Box Company, Limited, with a capital of £60,000; the Anglo-Colonial Syndicate, Limited, with a capital of £100,000, to work mines in Cape Colony, the Transvaal Republic, and other parts of South Africa; the Monte Christo Gold Mines, Limited (Queensland), with a capital of £150,000; Bishop's Creek Gold Mining Company, Limited, with a capital of £100,000, to work mines in Queensland; Ashley's Patent Machine-made Bottle Company, Limited, with a capital of £200,000; Swansea Oil and Grease Company, Limited, with a capital of £15,000; the Property Realisation Company, Limited, with a capital of £50,000; Weaver Hall Brine, Salt, and Chemical Company, Limited, with a capital of £150,000; the Aubriot Enamels Syndicate, Limited, with a capital of £11,000; the Colonial Ammunition Company, Limited, with a capital of £50,000; Heaton's Cloisonné Mosaic, Limited, with a capital of £5,000; William Wilkinson and Sons, Limited, with a capital of £5,000, to carry on business as shear manufacturers; the Manchester Mat Manufacturing Company, Limited, with a capital of £6,000; Ira Ickringill & Co., Limited, with a capital of £80,000, to carry on a wool combing and worsted spinning business at Keighley; Manila Railway Company, Limited, with a capital of £500,000; President Gold Mining Company, Limited (South Africa), with a capital of £52,000; Patent Hydraulic Freestone Company, Limited, with a capital of £10,000; and Plas Winter Halkyn Mining Company, Limited, with a capital of £12,000. A total of 212 companies, with an aggregate capital of £19,463,758, were registered during last month; the figures for January, 1887, being £7,433,270.

COAL.—The total imports of coal into London during January amounted to 1,172,109 tons, as compared with 1,143,124 tons in the same month of last year. The total exported was 274,473 tons, as compared with 240,862 during the same period of 1887.

COPPER.—The total stocks of copper in England and France on 31st January, together with the quantities advised from Chili and Australia, are stated by Messrs. Merton at 45,692 tons.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 29th January, amounted to £1,130,061, on 15,831¼ miles, as compared with £1,102,105 in the corresponding period of 1887, when the mileage was 15,706¾ miles. An increase is thus shown in the mileage of 124¾ miles, or 0·7 per cent., and in the receipts of 2·5 per cent.

THE PARIS INTERNATIONAL EXHIBITION.—The Council of the Telegraph Engineers and Electricians is taking steps to organise an English Electrical Section. A circular has been issued to the leading electrical firms in this country inviting them to attend a meeting at the offices of the society, 4, The Sanctuary, Westminster, on Monday afternoon next, to consider the measures to be adopted in connection with the Exhibition. The Paris secretary of the Society, who has been in communication with the Director-General on the subject, will be present to give all necessary explanations.

SOCIETY OF ENGINEERS.—The first ordinary meeting of this Society was held on Monday evening, when the president, Mr. Arthur T. Walmsley, delivered his inaugural address, in which he reviewed the work of last session, and drew special attention to the various works in progress which had been visited during the summer vacation. In speaking of the future prospects of the profession and of trade, he pointed out the necessity of a personal inquiry into the requirements of foreign markets.

TECHNICAL EDUCATION.—A special course of lectures, commencing on 16th inst., is to be given at the Finsbury Technical College, by Professor Perry, on the mechanical engineering involved in the design and manufacture of dynamo machines and motors. These lectures will be of a thoroughly practical character, illustrated by working drawings and dynamos actually constructed by leading makers. There will also be drawing office work in connection with the same subject.

GLASGOW, 9TH FEBRUARY, 1888.

PIG IRON.—The market is still extremely flat. A fall of about 5s. per ton in all has taken place during the last few weeks, and if the price has now reached its lowest point there seems no immediate prospect of permanent recovery. The revival occasioned by the placing of shipbuilding orders seems to have passed away, and no other elements in the economic situation suffice to afford any new impetus.

SHIPBUILDING AND ENGINEERING.—Messrs. Lees, Anderson, & Co. have secured an order for a set of triple expansion engines for a steamer to be built at Londonderry at the Foyle Shipbuilding yard of Mr. Charles Biggar. The steamer is intended for the Londonderry trade of Messrs. A. A. Laird & Co., of Glasgow. A considerable number of yachting contracts have been placed during the past few days. Four of these have been designed by Mr. G. L. Watson, one of which, a large racing yacht, is to be built by Messrs. D. & W. Henderson & Co., the builders of the "Thistle." Another is to be built by the Culzean Shipbuilding Company, Ayr, and two others are to be built by the well known yacht builders, Messrs. Wm. Fyfe & Son, Fairlie, on the Clyde. One of the latter is said to be designed as a centre board boat. Messrs. Fleming and Ferguson, Paisley, have been commissioned by Mr. Sholto Douglas, of Coatbridge, to build a 40-ton steel yacht. The same firm will fit the vessel with their patent quadruple expansion engines.

MINERAL SHIPMENTS.—The mineral shipments last week show an increase over those of the corresponding period last year. Pig iron shipments show a large increase—from 5646 tons during the same week of last year to 8367 tons last week. Freights are various and fluctuating from day to day. There seems a tendency in Bombay freights to fall off, though others remain firm.

THE MINERAL OIL TRADE.—An amalgamation has now practically been effected by the Scottish mineral oil companies. Prices have been fixed according to a scale agreed upon, and although all the companies have not yet given in their adhesion, the syndicate is so far definitely formed that no practical difficulty is anticipated.

PHILOSOPHICAL SOCIETY.—On Wednesday evening, by invitation of Sir William Thomson, the Philosophical Society met in the natural philosophy class room in the University. Prof. MacKendrick exhibited and explained Von Fleischl's spectro-polarimeter for the estimation of grape sugar, a gas pump for the removal of gases from the blood, and other mechanical appliances for the study of physiological physics. Sir William Thomson then read a paper upon "A new composite form of electric balance adapted to measure currents from $\frac{1}{10}$th of an ampère to 500 ampères." This instrument may also be used as a volt meter and watt meter, and forms an important addition to the series of electric measuring instruments which were described in *Industries* for January 27th.

THE TECHNICAL COLLEGE.—The Glasgow and West of Scotland Technical College has arranged for the delivery of a course of lectures upon "Navigation." This important feature will supplement the existing opportunities for instruction in the principles of navigation, and facilitate the studies of those who are preparing for Board of Trade examinations.

FORTH BRIDGE RAILWAY COMPANY.—The half yearly meeting of the company was held on Tuesday. The report presented by the engineers indicated a prospect of this undertaking being completed in October, 1889; and the adverse rumours lately circulated in some quarters were contradicted by the official report of satisfactory progress. A special meeting was subsequently held to authorise parliamentary proceedings for the raising of additional capital.

(From our own Correspondents.)

LIVERPOOL, 8TH FEBRUARY, 1888.

THE WATER SUPPLY OF LIVERPOOL.—An alarming statement was made by Alderman Anthony Bower, at the last meeting of the Water Committee, concerning the serious condition of the water supply at the present time. It appears that this time last year there were 3,700,000,000 gallons stored in the reservoir at Rivington, whereas at the present time there are only 1,015,000,000 gallons in stock. Liverpool, however, is not entirely dependent upon the supply from Rivington. A sub-committee has been formed to consider the question of obtaining a temporary supply from elsewhere, and the Water Committee had every reason to hope, that although the present supply was in such a serious condition, the precautionary steps they were now taking would prevent the possibility of a water famine taking place. At a previous meeting they had decided not to obtain the proposed preliminary supply from the Vyrnwy works, on account of the great expense.

LIVERPOOL UNIVERSITY COLLEGE EXTENSION.—An enthusiastic meeting of the governors, members of the senate, and friends of the University was held on Monday, to consider the question of erecting permanent college buildings, which are estimated to cost £35,000. A subscription list was opened, headed by Lord Derby, with £1,000; the same amount being also subscribed by the Mayor of Liverpool, Mr. George Holt, Mr. Henry Tate, Mr. Alfred Booth, and Mr. E. K. Muspratt. The building for the Walker Engineering Laboratory is progressing favourably, the sub-structure being completed. Mr. A. Waterhouse, R.A., is the architect for all the buildings in connection with the University, including the chemical laboratory completed, the engineering laboratory in course of erection, and the proposed new permanent buildings.

SHEFFIELD, 8TH FEBRUARY, 1888.

IRON AND STEEL.—The Sheffield trade continues to improve. Large quantities of iron and steel, particularly Bessemer, are changing hands, and the output is much more extensive than it was a year ago. Railway material is in growing demand, and rails for home and colonial use are being urgently inquired for. Several large orders have recently been placed with Sheffield houses for railway material at rather better prices. Messrs. Charles Cammell & Co. are very busy in their rail mills at Workington, turning out great supplies of steel rails for shipment to distant markets. Another well known firm near Sheffield has also secured good orders for steel rails of best quality. An interesting fact in connection with modern manufacture is that one local firm, largely engaged in making first quality railway material, pays no less than £2,000 a year for analysis alone. Engineers are still actively employed on good orders, and there is plenty of work at the rolling mills. Edge tool makers are tolerably busy, and both the cutlery houses and the silver-plating firms are doing a more satisfactory business.

LEEDS, 8TH FEBRUARY, 1888.

THE HEAVY TRADES.—The fall in the price of pig iron has had comparatively little effect upon local trade. There

Digitized by Google

is little anticipation of a further drop, and makers think the present healthy prices will be maintained. The engineers are well employed on heavy machinery; and there is a more encouraging inquiry for locomotives, and various descriptions of railway material. A number of very large boilers have lately been turned out, and heavy work for shipbuilding is in better request. There are also a few orders on hand for steam tram engines. Whether these engines will ever be equipped with anything like the American cow catcher it is impossible to say. Perhaps something may be done to diminish the danger to children who so carelessly get on the track in some of our large towns. A good business is being done in machine tools, as has been done for some weeks past. Cut nails also find a ready market.

EXPORTS.—It is a significant fact that Leeds is greatly developing its woollen and worsted trade with the United States. Its exports in woollens, worsteds, and cotton, in January, 1887, amounted to £21,480; during the past month the exports have increased to £24,191. The value of metals and machinery sent to the States during the past month amounted only to £2,624, compared with £5,142 in January last year; £4,822 was the value of hair and wools exported from Leeds, compared with only £1,191 in the first month of 1887. For the first month of this year the total exports amount to £37,381, compared with £34,474 in January, 1887, showing an increase of 8½ per cent.

NORTH STAFFORDSHIRE, 8TH FEBRUARY, 1888.

NORTH STAFFORDSHIRE RAILWAY COMPANY.—The half yearly meeting of this company was held in London on Friday last. The report recommended a dividend of 4¼ per cent. on the ordinary shares, a balance of £2,346 being carried forward. The accounts showed an increase of £3,255 from coaching traffic, and £8,030 from minerals. The chairman suggested, in moving the adoption of the report, that the capital expenditure, which had now been brought down to something like £5,000 per annum, should in future be debited to revenue. Owing to the spirited policy pursued by the present traffic manager, Mr. W. D. Phillips, the value of this property has developed considerably, and the company are now able to provide a dividend about double that which was paid a few years ago. The increase in mineral traffic appears to point to an enlarged volume of trade over the past year.

THE POTTERIES.—Mr. W. H. Turner, of Tunstall, has patented a pottery printing machine which is likely to effect a considerable saving of labour and expense in printing on china and earthenware. It is already in operation at several large manufactories. The printing is done from coils of paper drawn over cylindrical plates on the principle of the machinery used in the printing of some newspapers. It produces good, regular, and even work, and in large establishments, where the demand for printed goods is great, its adoption would effect a large saving in labour. The first cost of the necessary arrangements for printing by this patent is much less than that required for the old method.

COAL MINES REGULATION ACT.—The provisions of this Act with regard to blasting are still causing great trouble in this district, the men refusing to comply with them except at an advance in the price of getting. The multiplication of foremen and other officials is having a detrimental effect on the cost of getting.

BIRMINGHAM, 8TH FEBRUARY, 1888.

THE IRON TRADE.—There is a slight lull in the local iron trade, which is rather of the nature of a failure to go forward than of an actual retrogression. Business is fairly steady, and prices remain unchanged. There is a tendency to increase the output of pig iron, and it is stated that there are now 30 blast furnaces at work in South Staffordshire, against 27 this time last year. The output of these is on an average about 220 tons per week, and a rather hopeful feeling prevails in this branch of the trade. The present crisis in Europe, however, is tending to unsettle matters somewhat. Unmarked iron is fairly active at £5 to £5. 10s., but the marked iron is not in good request at £7 for first and £6 for second qualities. The galvanisers are busy in the sheet departments, many having orders that will occupy them for a month or two. In the hollow ware and wire netting shops there is no pressure, but not much scarcity of work.

THE HARDWARE TRADE.—The revival in railway traffic is leading to a demand for locomotive tubes, carriage fittings, and general stores. The makers of agricultural implements, trowels, rakes, shovels, &c., are busy, many of these goods going to foreign markets. Australia, India, and South America are improving in this respect, and better prospects are apparent with regard to several European countries. The gun trade is better off than formerly, and the brass trades are fairly occupied, although still crippled by the dearness of copper. The makers of cycles or cycle parts for export are busy. Ammunition of the smaller sizes is not much in demand, but Messrs. Kynoch & Co. and the Small Arms and Ammunition Company are well engaged upon shells for machine guns. The works of the Aluminium Company at Oldbury are progressing rapidly. This company has a capital of half a million sterling, the works occupying 4½ acres of ground, and it is expected that the metal will be produced to the extent of 300lb. per day, at a cost of less than £1 per pound. Sodium will also be manufactured by Castner's process.

LEICESTER, 8TH FEBRUARY, 1888.

WOOL, SPINNING, AND YARN TRADES.—There has been very little alteration in business since the last report; whilst there is no diminution, there is not any increase. Prices remain unaltered, but, if anything, the tone of the market is firmer, and the recent London sales have tended to confirm the tendency. Growers and country dealers still hold out for full rates; but staplers are not inclined to buy, and hence it becomes a question of who can wait the longest. Staplers are not doing much, as spinners are not very busily employed, and their purchases are small and to cover present wants only. Spinners are experiencing considerable difficulty in keeping their machinery employed. It is stated that there are heavy stocks on hand of yarn, and that lower prices have been taken to clear them out. Yarn merchants are not doing very much business. Yarns generally are firm in price, and cashmeres especially so.

HOSIERY TRADE.—There is a slight improvement in most branches of the manufacture, but generally firms are not very busy. Plain hosiers are fairly well off, but manufacturers of specialties are the best employed, and it is likely they will continue so. Buyers are now moving amongst the various houses, and it is anticipated that there will shortly be a considerable accession of business.

SOUTH WALES, 8TH FEBRUARY, 1888.

CARDIFF DOCKS.—Rapid progress is being made in the matter of rendering these docks unrivalled for the quick dispatch of steamers loading coal. By means of Messrs. Lewis & Hunter's cranes an average of 250 tons per hour can be put into the ships' holds, but how largely this can be increased will be seen from the fact that for a portion of the time the steamship "Ambient" was loaded at the rate of 428 tons per hour—a feat quite unprecedented. The "Asama," a new steel steamer, is sailing with 9000 tons of coal on board—the largest quantity any ship has sailed with from Cardiff. The dock authorities are also engaged in a scheme to light their property by electricity. The first installation is to consist of twenty-two arc lights, each of between 2000 and 3000 c.p., which will be placed at the entrance of the docks and basins. The lights are to be carried in couples on poles about 40ft. high, and so arranged that by means of coloured lenses they can be used for signalling with ships lying in the Roads. The motive power is to be obtained from two of Messrs. Davy Paxman & Co.'s engines; the purely electrical apparatus having been supplied by Messrs. Crompton & Co.

PROPOSED SCHOOL OF ENGINEERING FOR CARDIFF.—On the first of this month a meeting of the Council of the University of South Wales was held to consider the report of the Principal on the above subject. The Principal recommended the recently established school in the Yorkshire College as an ultimate model; but at present the want of funds would preclude the possibility of establishing such a school in Cardiff. The scheme proposed for consideration under present circumstances involves an extension of the workshop already erected by the building of a fitting and pattern making shop, and the acquirement of some modern machine tools.

BARROW-IN-FURNESS, 8TH FEBRUARY, 1888.

MINING ENTERPRISE.—The Hodbarrow Mining Company have determined, subject to the approval of the Board of Trade, to construct an enormous sea embankment at the margin of their mines on the Duddon Estuary, with the object of preventing the sea getting into their workings. This will cost not less than £50,000, and is considered a necessary expenditure of money in view of the great value of the hematite ore found in this place. It always commands from 1s. to 2s. per ton more than any other ore in the district, by reason of the high percentage of metal it contains. The demand for iron ore remains steady, at from 9s. 6d. to 12s. 6d. per ton net at mines.

IRON AND STEEL.—There is a brisk demand for both iron and steel, although the markets are not buoyant. Pig iron is quoted at 43s. 6d. to 44s. for mixed numbers of Bessemer iron; but "bearing" operations are said to be responsible for the quieter tone which pervades the market, despite the evidences which are everywhere apparent of the activity which characterises all the industries which use hematite iron or Bessemer and Siemens-Martin steel. The quotations for steel are practically the same as last week.

MIDDLESBROUGH, 8TH FEBRUARY, 1888.

PIG IRON.—The market is very quiet, and prices have fallen, although they are but nominal. Makers have little or none to offer at present, and what little is done is amongst merchants. As low as 31s. 6d. per ton for No. 3 G.M.B. prompt delivery has been quoted by sellers, but even at this buyers are not to be had. Warrants are quoted at 31s. per ton cash for Connal's No. 3 G.M.B., and Connal's No. 1, 2, and 3 hematite at 42s. 6d. per ton.

SALT.—The boring for salt at Seaton-Carew has turned out a failure, after having been carried down for 1200ft. without finding salt. The geological indications have induced the company to continue their boring in the hope of finding coal.

IRON MASTERS' RETURNS.—These returns, which have been looked forward to with considerable expectation, have turned out more favourable than anticipated. There has been an increase of 6599 tons added to stocks during the month of January. The increase was expected to be 10,000 tons. There has been an increase in the make of pig iron amounting to 2208 tons, and a decrease in the shipments of 4873 tons, as compared with those of December. There has been an increase in the make of Cleveland iron, amounting to 2380 tons over December, and a decrease in the make of hematite, &c., of 172 tons.

NEWCASTLE, 8TH FEBRUARY, 1888.

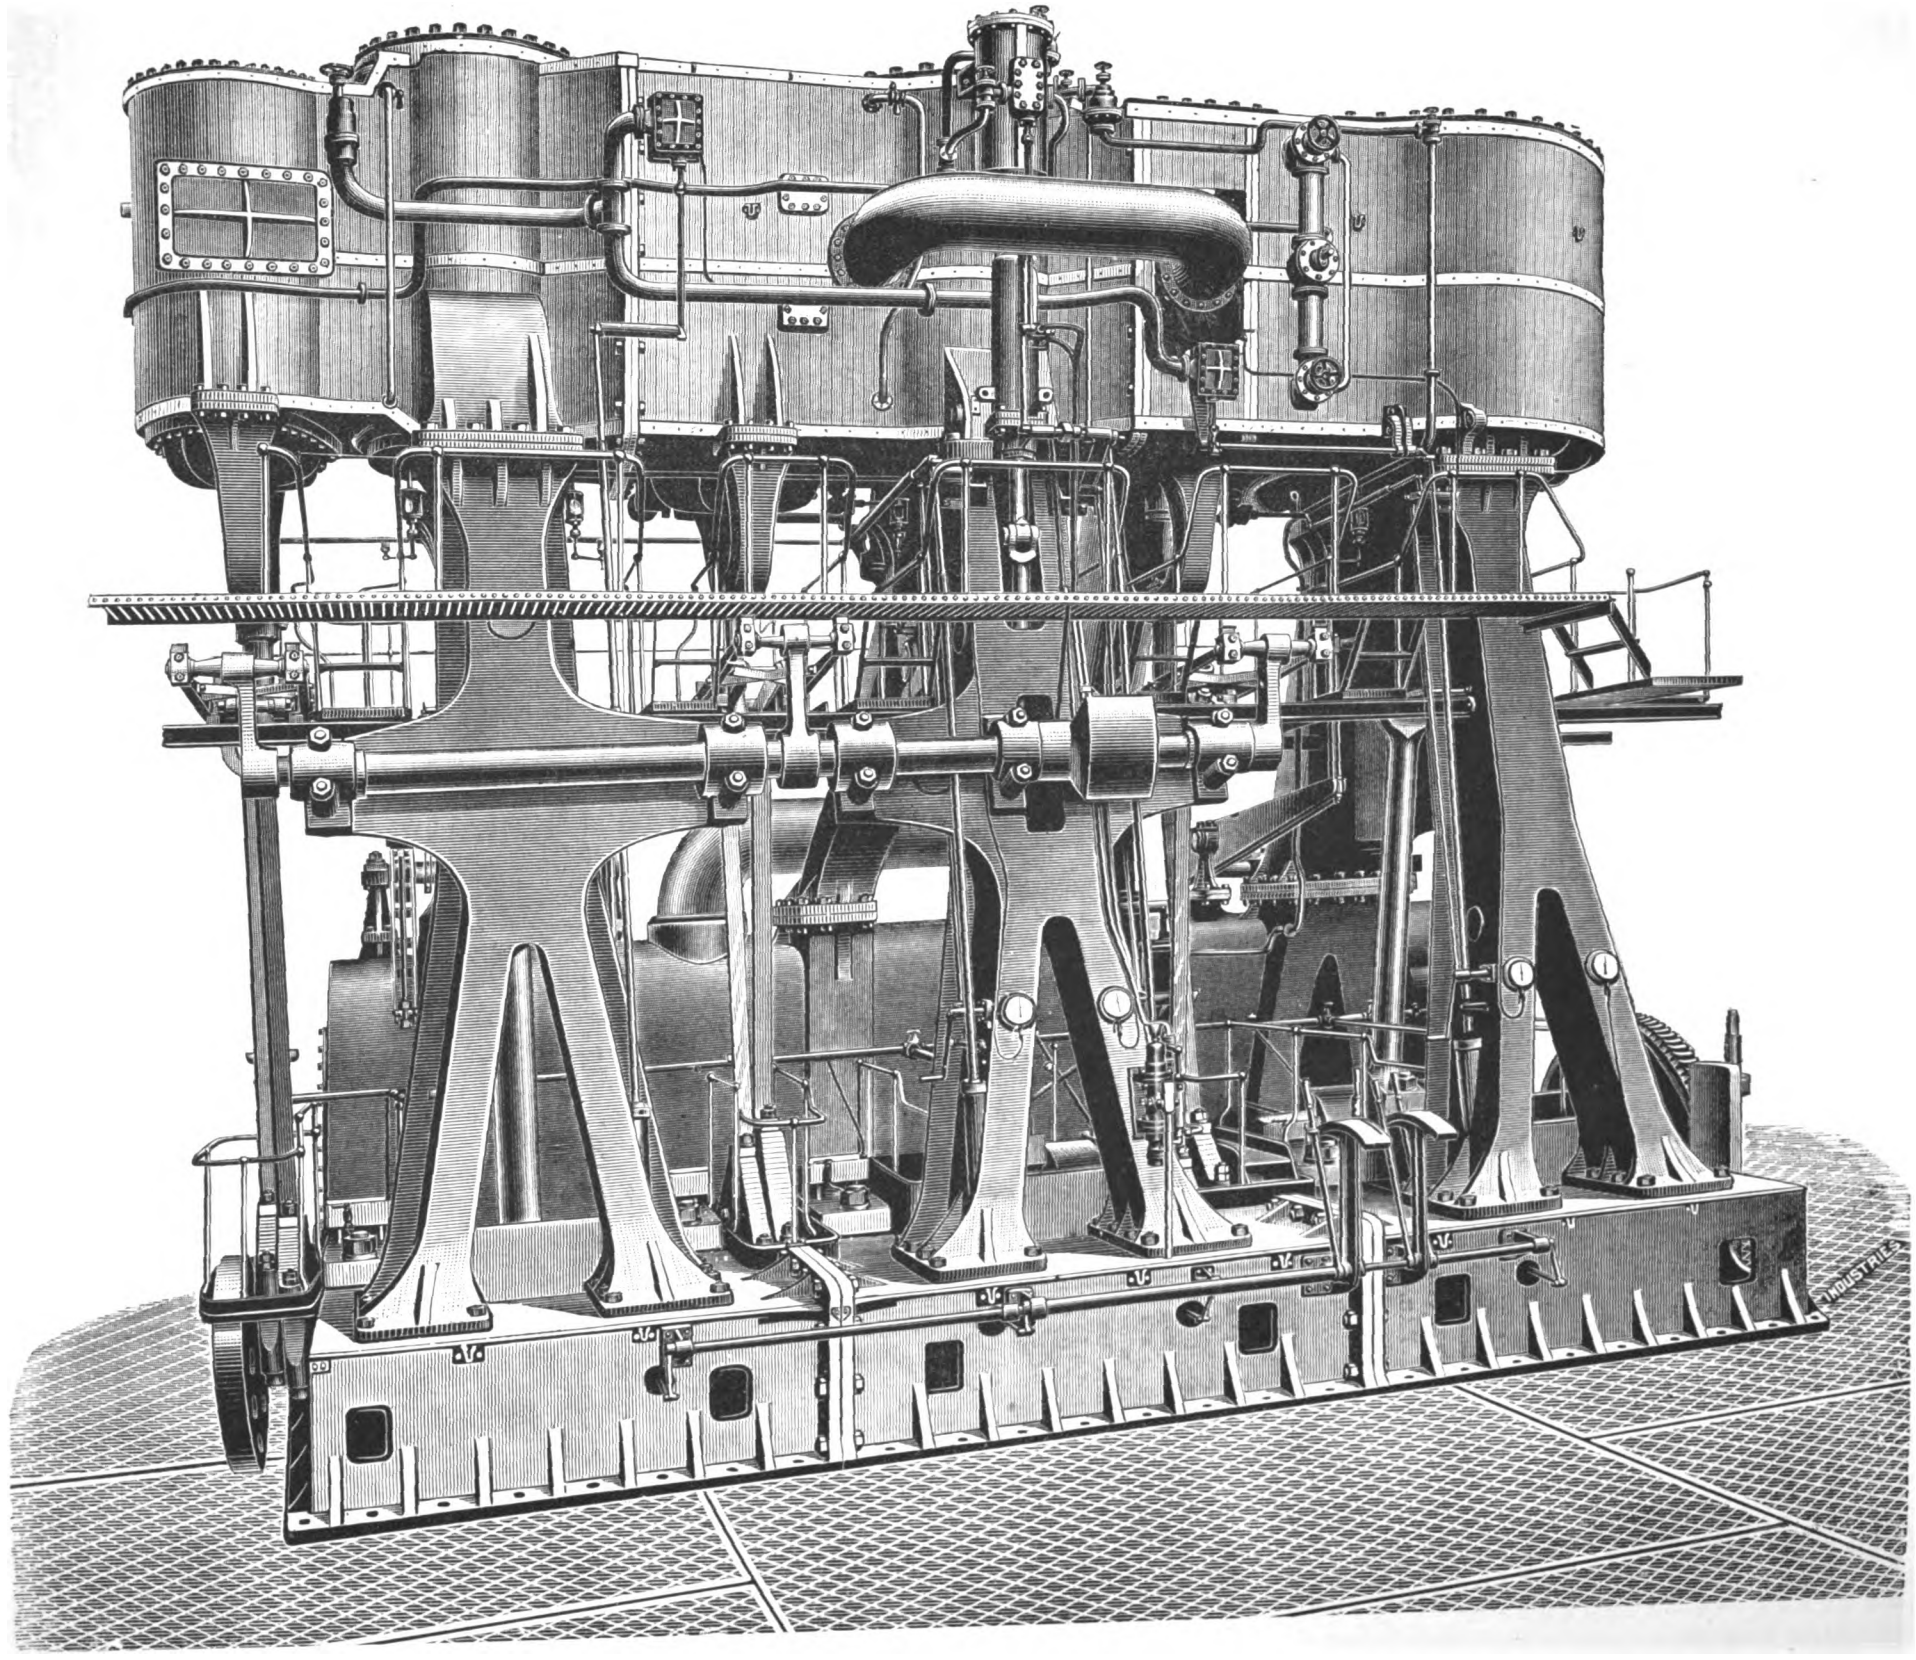
SHIPBUILDING.—Messrs. Armstrong, Mitchell, & Co. have just put down the keels for four vessels of considerably more than the average dimensions, and a berth is being cleared for the laying down of a fifth vessel. They have ordered from the patentees (Messrs. Arthur Dixon & Co., Wallsend) a powerful frame bevelling machine, and it is intended that this shall be utilised in connection with a new frame furnace of improved design, the erection of which has lately been completed. Messrs. W. Richardson and Co., having effected the sale of an exceptionally large steamer, which was originally intended to form one of the now defunct Monarch Line, are altering the stern to what is commonly known as the "clipper" type, and are making other changes which seem to indicate that the vessel is meant for service on one of the great ocean routes, for the conveyance of passengers as well as ordinary cargo. Messrs. R. Stephenson & Co. have secured an order, from Messrs. Wilson, of Hull, for a steel steamer, to be over 400ft. in length. The firm have also orders for two composite lightships, and other vessels. The new boiler and engine works which this firm are erecting in connection with their shipbuilding works, are now so nearly completed that operations in the boiler department are expected to be commenced by the middle of March. Messrs. Hawthorn, Leslie, & Co. have some important orders to proceed with, but frame turning has been stopped for some days owing to the non-delivery of materials. The difficulty of procuring supplies of steel continues to be a source of great inconvenience to shipbuilders on the Tyne, as well as at other northern ports. Messrs. Palmer & Co. have now seven berths occupied. This constitutes the whole of their building accommodation at their Jarrow establishment with the exception of one berth, and it is expected that this will very shortly be filled by a keel. The Tyne Shipbuilding Company and Messrs. Edwards & Sons have each laid down keels for vessels lately, and it may be stated that the latter firm have a good deal of repair work in hand.

ENGINEERING.—The works belonging to Messrs. Hawthorn, Leslie, & Co., at Forth Banks, as well as those at St. Peter's, are extremely active, the marine orders in hand being sufficient to provide full occupation for the machinery in both establishments. Messrs. W. Richardson and Co. are making engines for a large vessel lately launched by Messrs. Hawthorn, Leslie, & Co., to the order of Messrs. Milburn, Newcastle. The North-Eastern Engineering Company, Wallsend, are about to utilise some steam hammers which have hitherto been inoperative, in manufacturing a portion of the heavy forgings required in their own establishment. Night work is still the rule at this and other marine works on the river. Those establishments that are devoted to other branches of engineering are, on the whole, doing well. Messrs. Clark, Chapman, Parsons, & Co. are receiving a good many orders for steam winches, steering gears, &c., and those departments of their works are again quite busy. Messrs. H. Watson & Sons, High Bridge, Newcastle, are having a well sustained demand for their various specialties, and their extensive resources are being put to a somewhat exceptional strain. Messrs. Donkin and Nichol, of the St. Andrew's Engine Works, are also very busy. Among other contracts in hand by this firm is one for the fitting up of electric bells and telegraphs in the three passenger steamers for the Hall Line, now being completed by Messrs. Palmer, and one for the fitting of similar appliances in the armour plated ship "Victoria," now receiving the finishing touches at Elswick.

BELFAST, 8TH FEBRUARY, 1888.

SHIPBUILDING AND ENGINEERING.—Trade still continues to be good, and large numbers of hands are now employed, especially in the shipbuilding yards. Machine makers, who have been suffering from the long continued depression in the linen trade, are now finding more work. Boiler makers have several orders on their books both for land and marine work. The various shipbuilders are preparing handsome models for the coming Glasgow Exhibition.

WOOLLEN TRADE.—The efforts which are being made by Irish woollen manufacturers to extend their trade are meeting with very encouraging success. The exports are very much increased, and the goods give much satisfaction. A special effort is now being made to increase the home trade, which is not nearly so large as it might be.



LINEN TRADE.—The late advance in prices still continues to be maintained; a steady trade is being transacted, while stocks are diminishing. The demand for yarns continues steady, with prices as before. Tows are in good demand, and prices are expected to rise. Cloths, brown goods, and finished linens are in improved demand, with prices in most instances hardening. Exports continue well up to the average. The supply of home grown flax is becoming very limited, and for good quality a high price has to be paid. Owing to an accident in the engine room, the large factory of the Braidwater Spinning Company, at Ballymena, has had to be closed, and over a thousand hands have been thrown out of employment for some weeks.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 3d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*
